3 Membranes and Cell Organelles

3.1 The preparation of subcellular organelles from mouse liver in self-generated gradients of iodixanol.
Graham, J., Ford, T. and Rickwood, D.
*Anal. Biochem., **220**, 367-373 (1994*)

This paper reports the use of a new density gradient compound, **iodixanol**, for the resolution of the major organelles from mouse liver. A major advantage of iodixanol over other iodinated density gradient media is its ready ability to form self-generated gradients. Gradient-forming conditions have been modulated to provide optimal recoveries of Golgi membranes, lysosomes, mitochondria and peroxisomes. The organelles were isolated in high yield (80-90% of gradient input) and high purity. Nycodenz and iodixanol were compared using preformed gradients. Iodixanol provided resolution superior to that of Nycodenz, notably of peroxisomes and mitochondria and the separation of lysosomes from endoplasmic reticulum. Because iodixanol does not interfere significantly with marker enzyme activities, gradient fractions can be analyzed without removal of the gradient media.

3.2 A detergent-free method for purifying caveolae membrane from tissue culture cells.
Smart, E.J., Ying, Y-S, Mineo, C. and Anderson, R.G.W.
*Proc. Natl. Acad. Sci. USA, **92**, 10104-10108 (1995)*

Current methods for purifying caveolae from tissue culture cells take advantage of the Triton X-100 insolubility of this membrane domain. To circumvent the use of detergents, we have developed a method that depends upon the unique buoyant density of caveolae membrane. The caveolae fractions that we obtain are highly enriched in caveolin. As a consequence we are able to identify caveolae-associated proteins that had previously gone undetected. Moreover, resident caveolae proteins that are soluble in Triton X-100 are retained during the isolation.

3.3 Acylation targets endothelial nitric-oxide synthase to plasmalemmal caveolae.
Shaul, P.W. et al
*J. Biol. Chem., **271(11)**, 6518-6522 (1996)*

Endothelial nitric-oxide synthase (eNOS) generates the key signaling molecule nitric oxide in response to intralumenal hormonal and mechanical stimuli. We designed studies to determine whether eNOS is localized to plasmalemmal microdomains implicated in signal transduction called caveolae. Using immunoblot analysis, eNOS protein was detected in caveolar membrane fractions isolated from endothelial cell plasma membranes by a newly developed detergent-free method; eNOS protein was not found in noncaveolar plasma membrane. Similarly, NOS enzymatic activity was 9.4-fold enriched in caveolar membrane versus whole plasma membrane, whereas it was undetectable in non-caveolar plasma membrane. 51-86% of total NOS activity in postnuclear supernatant was recovered in plasma membrane, and 57-100% of activity in plasma membrane was recovered in caveolae. Immunoelectron microscopy showed that eNOS heavily decorated endothelial caveolae, whereas coated pits and smooth plasma membrane were devoid of gold particles. Furthermore, eNOS was targeted to caveolae in COS-7 cells transfected with wild-type eNOS cDNA. Studies with eNOS mutants revealed that both myristoylation and palmitoylation are required to target the enzyme to caveolae and that each acylation process enhances targeting by 10-fold. Thus, acylation targets eNOS to plasmalemmal caveolae. Localization to this microdomain is likely to optimize eNOS activation and the extracellular release of nitric oxide.

3.4 Clustered folate receptors deliver 5-methyltetrahydrofolate to cytoplasm of MA104 cells
Smart, E.J., Mineo, C. and Anderson, R.G.W.
*J. Cell Biol., **134(5)**, 1169-1177 (1996)*

Previously, a high affinity, glycosylphosphatidylinositol-anchored receptor for folate and a caveolae internalization cycle have been found necessary for potocytosis of 5-methyltetrahydrofolate in MA104. We now show by cell fractionation that folate receptors also must be clustered in caveolae for potocytosis. An enriched fraction of caveolae from control cells retained 65-70% of the [^{3}H]folic acid bound to cells in culture. Exposure of cells to the cholesterol-binding drug, filipin, which is known to uncluster receptors, shifted approximately 50% of the bound [^{3}H]folic acid from the caveolae fraction to the noncaveolae membrane fraction and markedly inhibited internalization of [^{3}H]folic acid. An mAb directed against the folate receptor also shifted approximately 50% of the caveolae associated [^{3}H]folic acid to noncaveolae membrane, indicating the antibody perturbs the normal receptor distribution. Concordantly, the mAb

inhibited the delivery of 5-methyl[^{3}H]tetrahydrofolate to the cytoplasm. Receptor bound 5-methyl [^{3}H]tetrahydrofolate moved directly from caveolae to the cytoplasm and was not blocked by phenylarsine oxide, an inhibitor of receptor-mediated endocytosis. These results suggest cell fractionation can be used to study the uptake of molecules by caveolae.

3.5 Localization of epidermal growth factor-stimulated Ras/Raf-1 interaction to caveolae membrane.
Mineo, C., James, G.L., Smart, E.J. and Anderson, R.G.W.
*J. Biol. Chem., **271(20)**, 11930-11935 (1996)*

An essential step in the epidermal growth factor (EGF)-dependent activation of MAP kinase is the recruitment of Raf-1 to the plasma membrane. Here we present evidence that caveolae are the membrane site where Raf-1 is recruited. Caveolae fractions prepared from normal Rat-1 cells grown in the absence of serum were highly enriched in both EGF receptors and Ras. Thirty seconds after EGF was added to these cells Raf-1 began to appear in caveolae but not in non-caveolae membrane fractions. The maximum concentration was reached at 3 min followed by a decline over the next 60 min. During this time EGF receptors disappeared from the caveolae fraction while the concentration of Ras remained constant. The Raf-1 in this fraction was able to phosphorylate MAP kinase, whereas cytoplasmic Raf-1 in the same cell was inactive. Elevation of cellular cAMP blocked the recruitment of Raf-1 to caveolae. Overexpression of Ha-Ras^{v12} caused the recruitment of Raf-1 to caveolae independently of EGF stimulation, and this was blocked by the farnesyltransferase inhibitor BZA-5B. Finally, prenylation appeared to be required for localization of Ras to caveolae.

3.6 A role for caveolin in transport of cholesterol from endoplasmic reticulum to plasma membrane.
Smart, E.J., Ying, Ys., Donzell, W.C. and Anderson, R.G.W.
*J. Biol. Chem., **271(46)**, 29427-29435 (1996)*

Caveolin is a 22-kDa membrane protein found associated with a coat material decorating the inner membrane surface of caveolae. A remarkable feature of this protein is its ability to migrate from caveolae directly to the endoplasmic reticulum (ER) when membrane cholesterol is oxidized. We now present evidence caveolin is involved in transporting newly synthesized cholesterol from the ER directly to caveolae. MA104 cells and normal human fibroblasts transported new cholesterol to caveolae with a half-time of approximately 10 min. The cholesterol then rapidly flowed from caveolae to non-caveolae membrane. Cholesterol moved out of caveolae even when the supply of fresh cholesterol from the ER was interrupted. Treatment of cells with 10 μg/ml progesterone blocked cholesterol movement from ER to caveolae. Simultaneously, caveolin accumulated in the lumen of the ER, suggesting cholesterol transport is linked to caveolin movement. Caveolae fractions from cells expressing caveolin were enriched in cholesterol 3-4-fold, while the same fractions from cells lacking caveolin were not enriched. Cholesterol transport to the cell surface was nearly 4 times more rapid in cells expressing caveolin than in matched cells lacking caveolin.

3.7 Subcellular colocalization of the cellular and scrapie prion proteins in caveolae-like membranous domains.
Vey, M. et al
*Proc. Natl. Acad. Sci. USA, **93**, 14945-14949 (1996)*

Results of transgenetic studies argue that the scrapie isoform of the prion protein (PrP^{Sc}) interacts with the substrate cellular PrP (PrP^{C}) during conversion into nascent PrP^{Sc}. While PrP^{Sc} appears to accumulate primarily in lysosomes, caveolae-like domains (CLDs) have been suggested to be the site where PrP^{C} is converted into PrP^{Sc}. We report herein that CLDs isolated from scrapie-infected neuroblastoma (ScN2a) cells contain PrP^{C} and PrP^{Sc}. After lysis of ScN2a cells in ice-cold Triton X-100, both PrP isoforms and an N-terminally truncated form of PrP^{C} (PrP^{C}-II) were found concentrated in detergent-insoluble complexes resembling CLDs that were isolated by flotation in sucrose gradients. Similar results were obtained when CLDs were purified from plasma membranes by sonication and gradient centrifugation; with this procedure no detergents are used, which minimizes artifacts that might arise from redistribution of proteins among subcellular fractions. The caveolar markers ganglioside GM1 and H-ras were found concentrated in the CLD fractions. When plasma membrane proteins were labeled with the impermeant reagent sulfo-N-hydroxysuccinimide-biotin, both PrP^{C} and PrP^{Sc} were found biotinylated in CLD fractions. Similar results on the colocalization of PrP^{C} and PrP^{Sc} were obtained when CLDs were isolated from Syrian hamster brains. Our findings demonstrate that both PrP^{C} and PrP^{Sc} are present in CLDs and, thus, support the hypothesis that the PrP^{Sc} formation occurs within this subcellular compartment.

3.8 Iodixanol (OptiPrep), an improved density gradient medium for the iso-osmotic isolation of rat liver peroxisomes.
Van Veldhoven, P.P., Baumgart, E. and Mannaerts, G.P.
Anal. Biochem. ***237****, 17-23 (1996)*

The suitability of **iodixanol**, a nonionic iodinated compound with a molecular weight of 1550, for the isolation of peroxisomes from rat liver was investigated. Centrifugation of light mitochondrial fractions in 20 to 40% (w/v) iodixanol gradients, made iso-osmotic by the addition of sucrose, resulted in an excellent separation of peroxisomes from the remaining organelles, which were not able to enter the gradient. Peroxisomes banded around 30% (w/v) iodixanol (d–1.175) and, as revealed by marker enzyme analysis, were enriched 35- to 40-fold. Morphological examination of the peroxisomal fractions confirmed the near absence of other organelles and revealed structurally well-preserved peroxisomes. Free cores, also present in the starting fractions, migrated to higher densities and were trapped on a cushion. No interference of iodixanol with marker enzyme determinations was observed, except for the UV-metric determination of urate oxidase and for the analysis of protein.

3.9 Potential chitinase activating factor from yeast cells of *Candida albicans*.
Jackson, D.J., Saunders, V.A. and Humphreys, A.M.
Lett. Appl. Microbiol., ***23****, 159-162 (1996)*

Microsomal chitinase from yeast and hyphal cells of *Candida albicans* was activated endogenously by incubation at 30^0C and exogenously by trypsin. The putative activating factor of yeast cells was separated from chitinase activity by fractionation of lysed protoplasts on an **Iodixanol** density gradient. The vacuole fraction contained no significant chitinase activity, but was enriched in chitinase activating factor. Activity of microsomal chitinase increased upon incubation with this, but no other gradient factor. Results suggest that the regulatory system governing microsomal chitinase activity, like that governing chitin synthase, involves a >vacuolar= activating factor in *Candida albicans*.

3.10 Localization of platelet-derived growth factor-stimulated phosphorylation cascade to caveolae
Liu, P., Ying, Y., Ko, Y.G and Anderson, R.G.W.
J Biol. Chem., 271(17), 10299-10303 (1996)

Previously we showed that interleukin lβ stimulates the conversion of sphingomyelin to ceramide in the caveolae fraction of normal human fibroblasts. The ceramide, in turn, blocked platelet-derived growth factor (PDGF) stimulated DNA synthesis. We now present evidence that the PDGF receptor initiates signal transduction from caveolae. Cell fractionation and immunocytochemistry show caveolae to be the principal location of PDGF receptors at the cell surface. Multiple caveolae proteins acquire phosphotyrosine when PDGF binds to its receptor, but the hormone appears to have little effect on the tyrosine phosphorylation of non-caveolae membrane proteins. Five proteins known to interact with the phosphorylated receptor were found to be highly enriched in caveolae membrane. PDGF caused the concentration of three of these proteins to significantly increase in the caveolae fraction. Finally, PDGF stimulated the association of a 190-kDa phosphoprotein with the caveolae marker protein, caveolin. Therefore, ceramide may modulate PDGF receptor function directly in caveolae.

3.11 Tissue-specific distribution and subcellular distribution of phospholipase D in rat: evidence for distinct RhoA- and ADP-ribosylation factor (ARF)-regulated isoenzymes.
Provost, J.J. et al.
Biochem. J., ***319(2)****, 285-291 (1996)*

Phospholipase D (PLD) is regulated by many factors including the small G-proteins, RhoA and ADP-ribosylation factor (ARF). The present study examined the distribution of RhoA- and ARF-responsive PLD in membranes, microsomes and cytosol of rat tissues and in rat liver subcellular fractions. PLD was present in all tissue fractions examined and was stimulated by guanosine 5'-[γ -thio]triphosphate (GTP[S]), with the highest specific activities being in lung, kidney and spleen. When myristoylated recombinant ARF (mARF) was added with GTP[S], the PLD activity was stimulated further, but the addition of RhoA was without effect. However, in extracts from crude membranes both mARF and RhoA enhanced the stimulation by GTP[S], with high specific activities of PLD being observed in all tissues except muscle. The response to mARF was usually greater than to RhoA, and the responses were additive, except for liver, which showed synergism. When the PLD activity of subcellular fractions of liver was examined, GTP[S] caused increases in all fractions except microsomes and mitochondria, which exhibited low activity. All fractions except mitochondria showed responses to RhoA and mARF, with the response to RhoA being greater in plasma membranes and that to

mARF being greater in Golgi and nuclei. Western blotting showed that RhoA was located mainly in the cytosol and plasma membranes, whereas ARF was principally in the cytosol. These findings demonstrate the widespread occurrence of significant activity of both Rho- and ARF-responsive forms of PLD in membranes from all tissues except muscle, and the presence of both forms in liver subcellular fractions except mitochondria. The large variations in the relative responses of PLD to Rho and ARF observed in different tissues and fractions support the existence of different isoforms of the enzyme.

3.12 Transport of an external Lys-Asp-Glu-Leu (KDEL) protein from the plasma membrane to the endoplasmic reticulum: studies with cholera toxin in Vero cells
Majoul, I.V., Bastiaens, P.I.H. and Soling H-D.
*J. Cell Biol., **133**, 777-789 (1996)*

The A2 chain of cholera toxin (CTX) contains a COOH-terminal Lys-Asp-Glu-Leu (KDEL) sequence. We have, therefore, analyzed by immunofluorescence and by subcellular fractionation in Vero cells whether CTX can be used to demonstrate a retrograde transport of KDEL proteins from the Golgi to the ER. Immunofluorescence studies reveal that after a pulse treatment with CTX, the CTX-A and B subunits CTX-A and CTX-B) reach Golgi-like structures after 15-20 min (maximum after 30 min). Between 30 and 90 min, CTX-A (but not CTX-B) appear in the intermediate compartment and in the ER, whereas the CTX-B are translocated to the lysosomes. Subcellular fractionation studies confirm these results: after CTX uptake for 15 min, CTX-A is associated only with endosomal and Golgi compartments. After 30 min, a small amount of CTX-A appears in the ER in a trypsin-resistant form, and after 60 min, a significant amount appears. CTX-A seems to be transported mainly in its oxidized form (CTX-A1-S-S-CTX-A2) from the Golgi to the ER, where it becomes slowly reduced to form free CTX A1 and CTX-A2, as indicated by experiments in which cells were homogenized 30 and 90 rain after the onset of CTX uptake in the presence of N-ethylmaleimide. Nocodazol applied after accumulation of CTX in the Golgi inhibits the appearance of CTX-A in the ER and delays the increase of 3', 5'cAMP, indicating the participation of microtubules in the retrograde Golgi-ER transport.

3.13 Murine SR-BI, a high density lipoprotein receptor that mediates selective lipid uptake, is N-glycosylated and fatty acylated and colocalizes with plasma membrane caveolae.
Babitt, J. et al
*J. Biol. Chem., **272(20)**, 13242-13249 (1997)*

The class B, type I scavenger receptor, SR-BI, was the first molecularly well defined cell surface high density lipoprotein (HDL) receptor to be described. It mediates transfer of lipid from HDL to cells via selective lipid uptake, a mechanism distinct from receptor-mediated endocytosis via clathrin-coated pits and vesicles. SR-BI is expressed most abundantly in steroidogenic tissues (adrenal gland, ovary), where trophic hormones coordinately regulate its expression with steroidogenesis, and in the liver, where it may participate in reverse cholesterol transport. Here we have used immunochemical methods to study the structure and subcellular localization of murine SR-BI (mSR-BI) expressed either in transfected Chinese hamster ovary cells or in murine adrenocortical Y1-BS1 cells. mSR-BI, an approximately 82-kDa glycoprotein, was initially synthesized with multiple high mannose N-linked oligosaccharide chains, and some, but not all, of these were processed to complex forms during maturation of the protein in the Golgi apparatus. Metabolic labeling with [^{3}H]palmitate and [^{3}H]myristate demonstrated that mSR-BI was fatty acylated, a property shared with CD36, another class B scavenger receptor, and other proteins that concentrate in specialized, cholesterol- and glycolipid-rich plasma membrane microdomains called caveolae. **OptiPrep** density gradient fractionation of plasma membranes established that mSR-BI copurified with caveolin-1, a constituent of caveolae; and immunofluorescence microscopy demonstrated that mSR-BI colocalized with caveolin-1 in punctate microdomains across the surface of cells and on the edges of cells. Thus, mSR-BI colocalizes with caveolae, and this raises the possibility that the unique properties of these specialized cell surface domains may play a critical role in SR-BI-mediated transfer of lipids between lipoproteins and cells.

3.14 Investigation of the role of lipids in the assembly of very low density lipoproteins in rabbit hepatocytes.
Cartwright, I.J. et al
*J. Lipid Res., **38**, 531-545 (1997)*

Our aims were (i) to determine which lipids co-localise with newly-synthesised apo-B in the lumen of the rough endoplasmic reticulum (RER), and thus may play a role in the stabilisation and/or translocation of this

protein: and (ii) to determine the intracellular sites of assembly of lipids into VLDL. In order to do this, we have developed a new method for the separation of ER derived microsomes on self-generated gradients of iodixanol (**OptiPrep)**.
Rabbit liver microsomes were resolved into two broad peaks, the lighter peak contained smooth vesicles, and the heavier peak contained rough vesicles. Each peak was collected in a number of fractions. A single gradient thus separates the initial events in the secretion process (RER fractions), from later events (SER fractions)**.** The microsomal fractions were separated into membranes and lumenal contents, and the mass of apo-B and VLDL lipids determined by ELISA or high performance thin layer chromatography, respectively. The biosynthetic relationships of apo-B and lipids were investigated, in timed or chase-experiments, by incubation of isolated rabbit hepatocytes with radiolabelled precursors of apo-B or lipids, followed by isolation, and analysis of the microsomal fractions. The results indicate that very small amounts of triacylglycerol, cholesterol and cholesterol ester co-localise with apo-B into the lumen of RER. The bulk of the VLDL lipids were in the lumen of the SER. However, some newly synthesised triacylglycerol, phospholipid, cholesterol and cholesterol ester were transferred to the lumen of the RER and were chased into the SER lumen. Double-labelling experiments, showed that cholesterol ester produced from newly synthesised cholesterol (labelled with [^{3}H]-mevalonate and [^{14}C]-oleate) was almost exclusively present in the RER, while cholesterol ester in the SER was labelled only with [^{14}C]-oleate. Thus, distinct intracellular lipid-pools may be involved at different stages in the assembly of VLDL.

3.15 Protein-disulfide isomerase-mediated reduction of the A subunit of cholera toxin in a human intestinal cell line.
Orlandi, P.A.
*J. Biol. Chem., **272(7)**, 4591-4599 (1997)*

A key step in the action of cholera toxin (CT) is the reduction of its A subunit to the A_1 peptide. The latter is an ADP-ribosyltransferase, which activates the α-subunit of the stimulatory G protein of adenylyl cyclase. In this study, the enzymatic reduction of membrane-bound CT in CaCo-2 human intestinal epithelial cells was characterized. Whereas diphtheria toxin was found to be reduced by a cell surface population of protein-disulfide isomerase (PDI) and its cytotoxicity was inhibited by *p*- chloromercuri-benzenesulfonic acid, bacitracin, or anti-PDI antibodies, these inhibitors had no effect on CT reduction or activity in intact cells. In contrast, the reduction of CT *in vitro* by either postnuclear supernatants (PNS) or microsomal membranes in the presence of Triton X-100 was significantly inhibited by p-chloromercuribenzenesulfonic acid and bacitracin. Anti-PDI monoclonal antibodies likewise inhibited the *in vitro* reduction of CT and also were effective in depleting reductase activity from PNS. Since inhibition and depletion were not observed in the absence of detergent, these results suggested that the reductase activity was a soluble component localized to the lumen of microsomal vesicles and correlated with the presence of protein-disulfide isomerase. This was further confirmed by showing a corresponding depletion of reductase activity and PDI in alkali-treated microsomes. This activity was restored when purified bovine PDI was added back to alkali-treated microsomes in a redox buffer that reflected conditions found in the lumen of endoplasmic reticulum (ER). When the CT-related reductase activity was assayed in subcellular fractions of PNS-derived membranes isolated on a 9-30% **iodixanol** gradient, the activity, as measured by CT-A_1 peptide formation localized to those membrane fractions containing the majority of cellular PDI. Furthermore, the banding density corresponded to a region of the gradient containing ER-derived membranes. These results indicated that CT was a substrate for PDI-catalyzed reduction in intact cells and supported the hypothesis that CT reduction and activation occurs in the ER.

3.16 The transmembrane domain of a carboxyl-terminal anchored protein determines localization to the endoplasmic reticulum.
Yang, M., Ellenberg, J., Bonifacino, J.S. and Weissman, A.M.
*J. Biol.Chem., **272(3)**, 1970-1975 (1997)*

UBC6 is a C-terminal membrane-anchored (type IV) protein, native to *Saccharomyces cerevisiae*, where it is found in the endoplasmic reticulum. When expressed in mammalian cells, this novel ubiquitin-conjugating enzyme also localizes to the endoplasmic reticulum. UBC6 lacks a lumenal domain and contains no known endoplasmic reticulum retention signals. Analysis of chimeric proteins in which the cytosolic domain of UBC is linked to a heterologous transmembrane domain, or in which the UBC6 transmembrane domain is appended to an unrelated soluble protein, led to the determination that the transmembrane domain of UBC6 plays a dominant role in its compartmental localization. The basis for the transmembrane domain-mediated subcellular targeting of UBC6 was evaluated by lengthening the wild type UBC6 hydrophobic segment from 17 to 21 amino acids, which resulted in re-targeting to the Golgi complex. A further increase in length to 26 amino

acids allowed this modified protein to traverse the secretory pathway and gain expression at the plasma membrane. These findings are consistent with models in which, in the absence of dominant cytosolic or lumenal targeting determinants, proteins may be sorted within the secretory pathway based on interactions between their transmembrane domains and the surrounding lipid bilayer.

3.17 Tyrosine kinase receptors concentrated in caveolae-like domains from neuronal plasma membrane
Wu, C., Butz, S., Ying, Y-S and Anderson, R.G.W.
J. Biol. Chem., ***272(6)***, *3554-3559 (1997)*

Recent evidence suggests that tyrosine kinases are highly organized in caveolae of tissue culture cells. We now report the isolation of a membrane domain from neuronal plasma membranes that has the biochemical characteristics of caveolae. A low density membrane (LDM) fraction with the same density as caveolae was highly enriched in tyrosine kinases such as insulin receptors, neurotrophin receptors, Eph family receptors, and Fyn. Grb2, Ras, heterotrimeric GTP-binding proteins, and Erk2 were also concentrated in the LDM. Incubation of the LDM fraction at 37°C stimulated the phosphorylation on tyrosine of multiple, resident proteins, whereas the bulk membrane fraction was devoid of tyrosine kinase activity. The LDM, which makes up ~5-10% of the plasma membrane protein, appears to be organized for signal transduction.

3.18 Physical association with Ras enhances activation of membrane-bound Raf (RafCAAX)
Mineo, C., Anderson, R.G.W. and White, M.A.
J. Biol. Chem., ***272(16)***, *10345-10348 (1997)*

The transforming activity of artificially membrane targeted Rafl suggests that Ras-mediated recruitment of Rafl to the plasma membrane is an important step in Rafl activation. Cellular Ras is concentrated in the caveolae, a microdomain of the plasma membrane that is highly enriched in caveolin, glycosylphosphatidylinositol-anchored proteins, and signal transduction molecules. Growth factor stimulation recruits Rafl to this membrane domain. Whether Ras simply promotes Rafl association with caveolae membranes or also modulates subsequent activation events is presently unclear. We have identified a ras variant, ras12V,37G, that does not interact with Raf1 but does interact with a mutant raf1, raf1(257L). To examine the role of Ras in the activation of membrane-bound Raf1, raf1CAAX, and raf1(257L)CAAX membrane-targeted variants of Raf1 and raf1(257L), respectively, were expressed in fibroblasts with or without coexpression of ras12V,37G. Cell fractionation localized both raf1CAAX and raf1(257L)CAAX to caveolae membranes independent of rasl2V,37G expression; however, coexpression of rasl2V,37G enhanced the activation of raf(257L)CAAX, but not raf1CAAX, as monitored by induction of cellular transformation, increased Raf kinase activity, and induction of activated MAP kinase. These results suggest that the Ras/Raf1 interaction plays a role in Raf1 activation that is distinct from membrane recruitment.

3.19 Organization of G proteins and adenylyl cyclase at the plasma membrane
Huang, C., Hepler, J.R., Chen, L.T., Gilman, A.G., Anderson, R.G.W. and Mumby, S.M.
Mol. Biol. Cell, ***8****, 2365-2378 (1997)*

There is mounting evidence for the organization and compartmentation of signaling molecules at the plasma membrane. We find that hormone-sensitive adenylyl cyclase activity is enriched in a subset of regulatory G protein-containing fractions of the plasma membrane. These subtractions resemble, in low buoyant density, structures of the plasma membrane termed caveolae. Immunofluorescence experiments revealed a punctate pattern of G protein α and β subunits, consistent with concentration of these proteins at distinct sites on the plasma membrane. Partial coincidence of localization of G protein α subunits with caveolin (a marker for caveolae) was observed by double immunofluorescence. Results of immunogold electron microscopy suggest that some G protein is associated with invaginated caveolae, but most of the protein resides in irregular structures of the plasma membrane that could not be identified morphologically. Because regulated adenylyl cyclase activity is present in low-density subtractions of plasma membrane from a cell type (S49 lymphoma) that does not express caveolin, this protein is not required for organization of the adenylyl cyclase system. The data suggest that hormone-sensitive adenylyl cyclase systems are localized in a specialized subdomain of the plasma membrane that may optimize the efficiency and fidelity of signal transduction.

3.20 Platelet-derived growth factor activates mitogen-activated protein kinase in isolated caveolae
Liu, P., Ying, Y-S., and Anderson. R.G.W.
Proc. Natl. Acad. Sci., USA, ***94****, 13666-13670 (1997)*

The ability of a peptide hormone to affect many different intracellular targets is thought to be possible because of the modular organization of signal transducing molecules in the cell. Evidence for the presence of signaling modules in metazoan cells, however, is incomplete. Herein we show, with morphology and cell fractionation, that all the components of a mitogen-activated protein kinase pathway are concentrated in caveolae of unstimulated human fibroblasts. Addition of platelet-derived growth factor to either the intact cell or caveolae isolated from these cells stimulates tyrosine phosphorylation and activates mitogen-activated protein kinases in caveolae. The molecular machinery for kinase activation, therefore, is preorganized at the cell surface of quiescent cells.

3.21 Aminopeptidase I is targeted to the vacuole by a nonclassical vesicular mechanism
Scott, S.V., Baba, M., Ohsumi, Y. and Klionsky, D.J.
J. Cell Biol., ***138(1)****, 37-44 (1997)*

The yeast vacuolar protein aminopeptidase I (API) is synthesized as a cytosolic precursor that is transported to the vacuole by a nonclassical targeting mechanism. Recent genetic studies indicate that the biosynthetic pathway that transports API uses many of the same molecular components as the degradative autophagy pathway. This overlap coupled with both in vitro and in vivo analysis of API import suggested that, like autophagy, API transport is vesicular. Subcellular fractionation experiments (**OptiPrep**) demonstrate that API precursor (prAPI) initially enters a nonvacuolar cytosolic compartment. In addition, subvacuolar vesicles containing prAPI were purified from a mutant strain defective in breakdown of autophagosomes, further indicating that prAPI enters the vacuole inside a vesicle. The purified subvacuolar vesicles do not appear to contain vacuolar marker proteins. Immunogold EM confirms that prAPI is localized in cytosolic and in subvacuolar vesicles in a mutant strain defective in autophagic body degradation. These data suggest that the cytosolic vesicles containing prAPI fuse with the vacuole to release a membrane-bounded intermediate compartment that is subsequently broken down, allowing API maturation.

3.22 Bisecting GlcNac structures act as negative sorting signals for cell surface Glycoproteins in forskolin-treated rat hepatoma cells
Sultan, A.S. et al
J. Biol. Chem., ***272(5)****, 2866-2872 (1997)*

The bisecting N-acetylglucosamine residue is formed by UDP-N-acetylglucosamine:β-D-mannoside-β-1,4-N-acetylglucosaminyltransferase III (GnT-III), a key branching enzyme for N-glycans. We found that forskolin, an adenylyl cyclase activator, markedly enhanced GnT-III at the transcriptional level in various hepatoma cells and hepatocytes, resulting in an increase of bisecting GlcNAc residues in various glycoproteins, as judged from the lectin binding to erythroagglutinating phytohemagglutinin (E-PHA). In whole cell lysates, the E-PRA binding was increased, and leukoagglutinating phytohemagglutinin (L-PHA) binding was decreased at 12 h after forskolin treatment, by time, both GnT-III activity and mRNA had reached the maximum levels. In contrast, the binding capacity as to E-PHA, determined by fluorescence-activated cell sorting on the cell surface, was decreased, suggesting that bisecting GlcNAc structures in certain glycoproteins changed the expression levels of glycoproteins and decreased their sorting on the cell surface. Fractionated organelles of M31 cells showed that the binding capacity as to E-PHA was mainly localized in Golgi membranes and lysosomes. This was also supported by a fluorescence microscopy. In order to determine whether or not the bisecting GlcNAc residue acts as a sorting signal for glycoproteins, N-oligosaccharide structures of lysosomal-associated membrane glycoprotein 1 and β-glucuronidase, γ-glutamyltranspeptidase, and secretory glycoproteins such as ceruloplasmin and α-fetoprotein were measured by E-PHA and L-PHA blotting after immunoprecipitation. The expression levels of lysosomal membrane glycoprotein 1 and γ-glutamyltranspeptidase on the cell surface were decreased at 12 h after forskolin treatment, indicating that the bisecting GlcNAc structure may act as a negative sorting signal for the cell surface glycoproteins and may alter the characteristics of hepatoma cells. This is the first report on glycoprotein sorting related to a specific structure of oligosaccharides, bisecting GlcNAc.

3.23 Rapid plasma membrane anchoring of newly synthesized $p59^{fyn}$. Selective requirement for NH_2-terminal myristoylation and palmitoylation at cysteine-3.
van't Hof, W. and Resh, M.D.
J. Cell Biol., ***136(5)****, 1023-1035 (1997)*

Abstract. The trafficking of Src family proteins after biosynthesis is poorly defined. Here we studied the role of dual fatty acylation with myristate and palmitate in biosynthetic transport of $p59^{fyn}$. Metabolic labeling of transfected COS or NIH 3T3 cells with [^{35}S]methionine followed by analysis of cytosolic and total membrane fractions showed that Fyn became membrane bound within 5 min after biosynthesis. Newly synthesized Src, however, accumulated in the membranes between 20-60 min. Northern blotting detected Fyn mRNA specifically in soluble polyribosomes and soluble Fyn protein was only detected shortly (1-2 min) after radiolabeling. Use of chimeric Fyn and Src constructs showed that rapid membrane targeting was mediated by the myristoylated NH_2-terminal sequence of Fyn and that a cysteine at position 3, but not 6, was essential. Examination of $G\alpha_0$-, $G\alpha_s$-, or GAP43-Fyn fusion constructs indicated that rapid membrane anchoring is exclusively conferred by the combination of N-myristoylation plus palmitoylation of cysteine-3. Density gradient analysis colocalized newly synthesized Fyn with plasma membranes. Interestingly, a 10-20-min lag phase was observed between plasma membrane binding and the acquisition of non-ionic detergent insolubility. We propose a model in which synthesis and myristoylation of Fyn occurs on soluble ribosomes, followed by rapid palmitoylation and plasma membrane anchoring, and a slower partitioning into detergent-insoluble membrane subdomains. These results serve to define a novel trafficking pathway for Src family proteins that are regulated by dual fatty acylation.

3.24 Molecular cloning and expression of a chloride ion channel of cell nuclei
Valenzuela, S.M. et al
*J. Biol. Chem., **272(19)**, 12575-12582 (1997)*

Ion channels are known to be present on the plasma membrane of virtually all cells and have been found on the membranes of various intracellular organelles. However, until recently they were believed not to occur at the nuclear membrane. In this study we describe the molecular cloning and characterization of a nuclear ion channel protein, designated nuclear chloride channel-27 (NCC27), from the human myelomonocytic cell line, U937. NCC27 is a novel chloride ion channel protein that was found to localize principally to the cell nucleus. Its only known homologue is a bovine chloride ion channel protein (p64) believed to localize to internal organelles. NCC27 therefore represents the first human member of a new class of organellar chloride ion channel proteins.

3.25 Bradykinin sequesters B2 bradykinin receptors and the receptor-coupled Gα subunits $G\alpha_q$ and $G\alpha_i$ in caveolae in DDT_1 MF-2 smooth muscle cells
de Weerd, W.F.C. and Leeb-Lundberg, L.M.F.
*J. Biol. Chem., **272(28)**, 17858-17866 (1997)*

In this report, we show that the vasoactive peptide agonist bradykinin (BK) when bound to B2 BK receptors on DDT_1MF-2 smooth muscle cells promotes the recruitment and sequestration of the occupied receptors and the receptor-coupled G-protein a subunits $G\alpha_q$ and $G\alpha_i$ in caveolae. Association of ligand receptor complexes and Gα subunits with caveolae was indicated by their co-enrichment on density gradients with caveolin, a marker protein for caveolae. Caveolin and Gα subunits were monitored by immunoblotting, whereas receptors were monitored as ligand receptor complexes formed by labeling receptors with the agonist BK or the antagonist NPC17731 prior to cell disruption and caveolae enrichment. These complexes were detected with radioligand and by immunoblotting with BK antibodies. A direct interaction of Gα subunits with caveolin was also indicated by their co-immunoprecipitation. Immunoelectron microscopy revealed that the enriched caveolin, Gα subunits, and BK receptor complexes were present in structures of 0.1-0.2 μm. At 4°C, BK and NPC17731 receptor complexes were detected in caveolae, and both complexes were sensitive to acid washing prior to cell disruption and caveolae enrichment. Elevation of the temperature to 37°C increased the amount of BK receptor complexes in caveolae with a maximal response at 10 min (continuous labeling) or 20 min (single-round labeling), and the complexes became acid-resistant. These conditions also increased the amount of $G\alpha_q$ and $G\alpha_i$. in caveolae with a maximal response at 5-10 min. In contrast, the NPC17731 receptor complexes remained acid sensitive and dissociated at this temperature, and antagonists did not increase the amount of Gα subunits in caveolae. These results show that some agonists that act through G-protein-coupled receptors promote the association of their receptors and receptor-coupled Gα subunits with caveolae.

3.26 Vacuoles induced by *Helicobacter pylori* toxin contain both late endosomal and lysosomal markers
Molinari, M.et al
*J. Biol. Chem., **272(40)**, 25339-25344 (1997)*

Intoxication of mammalian cells with the vacuolating toxin (VacA) released by *Helicobacter pylori* causes the formation of large acidic vacuoles containing the vacuolar ATPase proton pump and Rab7, a late endosome marker. Here, we describe a novel subcellular fractionation procedure, and we show that nanomolar concentrations of VacA induce a clear redistribution of lysosomal membrane glycoproteins among endocytic compartments. This redistribution is an early event in the process of cellular intoxication by VacA and precedes the formation of macroscopic vacuoles. The absence of the cation independent mannose 6-P receptor and the presence of Rab7 and of lysosomal membrane proteins in the newly formed compartment suggest that the vacuolating toxin induces the accumulation of a post-endosomal hybrid compartment presenting both late endosomal and lysosomal features.

3.27 Inhibition of endosome function in CHO cells bearing a temperature-sensitive defect in the coatomer (COPI) component ∈-COP

Daro, E., Sheff, D., Gomez, M., Kreis, T. and Mellman, I.
J. Cell Biol., ***139(7)***, *1747-1759 (1997)*

Abstract. Recent evidence has suggested that subunits of the coatomer protein (COPI) complexes are functionally associated with endosomes in mammalian cells. We now provide genetic evidence that COPI plays a role in endocytosis in intact cells. The 1D1F mutant CHO cell line bears a temperature-sensitive defect in the COPI subunit ∈-COP**.** In addition to exhibiting conditional defects in the secretary pathway, we find that the cells are also defective at mediating endosome-associated functions. As found for cells microinjected with anti-COPI antibodies, 1D1F cells at the restrictive temperature could not be infected by vesicular stomatitis (VSV) or Semliki Forest virus (SFV) that require delivery to acidic endosomes to penetrate into the cytosol. Although there was no temperature-sensitive defect in the internalization of receptor-bound transferrin (Tfn), Tfn recycling and accumulation of HRP were markedly inhibited at the restrictive temperature. Sorting of receptor-bound markers such as EGF to lysosomes was also reduced, although delivery of fluid-phase markers was only partially inhibited. In addition, lysosomes redistributed from their typical perinuclear location to the tips of the 1D1F cells. Mutant phenotypes began to emerge within 2 h of temperature shift, the time required for the loss of detectable ∈-COP**,** suggesting that the endocytic defects were not secondary to a block in the secretary pathway. Importantly, the mutant phenotypes were also corrected by transfection of wild-type ∈-COP cDNA demonstrating that they directly or indirectly reflected the ∈-COP defect. Taken together, the results suggest that ∈-COP acts early in the endocytic pathway, most likely inhibiting the normal sorting and recycling functions of early endosomes.

3.28 Identification of caveolin and caveolin-related proteins in the brain

Cameron, P.L., Ruffin, J.W., Bollag, R., Rasmussen, H. and Cameron, R.S.
J. Neurosci., ***17(24)***, *9520-9535 (1997)*

Caveolae are 50-100 nm, nonclathrin-coated, flask-shaped plasma membrane microdomains that have been identified in most mammalian cell types, except lymphocytes and neurons. To date, multiple functions have been ascribed to caveolae, including the compartmentalization of lipid and protein components that function in transmembrane signaling events, biosynthetic transport functions, endocytosis, potocytosis, and transcytosis. Caveolin, a 21-24 kDa integral membrane protein, is the principal structural component of caveolae. We have initiated studies to examine the relationship of detergent-insoluble complexes identified in astrocytes to the caveolin-caveolae compartment detected in cells of peripheral tissues. Immunolocalization studies performed in astrocytes reveal caveolin immunoreactivity in regions that correlate well to the distribution of caveolae and caveolin determined in other cell types, and electron microscopic studies reveal multiple clusters of flask-shaped invaginations aligned along the plasma membrane. Immunoblot analyses demonstrate that detergent insoluble complexes isolated from astrocytes are composed of caveolin-1 a, an identification verified by Northern blot analyses and by the cloning of a CDNA using reverse transcriptase-PCR amplification from total astrocyte RNA. Using a full-length caveolin-1 probe, Northern blot analyses suggest that the expression of caveolin-1 may be regulated during brain development. Immunoblot analyses of detergent-insoluble complexes isolated from cerebral cortex and cerebellum identify two immunoreactive polypeptides with apparent molecular weight and isoelectric points appropriate for caveolin. The identification of caveolae microdomains and caveolin-1 in astrocytes and brain, as well as the apparent regulation of caveolin-1 expression during brain development, identifies a cell compartment not detected previously in brain.

3.29 High-density-lipoprotein subfraction 3 interaction with glycosylphosphatidyl-inositol-anchored proteins

Nion, S. et al

*Biochem. J., **328**, 415-423 (1997)*

To elucidate further the binding of high-density-lipoprotein subfraction 3 (HDL_3) to cells, the involvement of glycosylphosphatidylinositol-anchored proteins (GPI-proteins) was studied. Treatment of cultured cells, such as fibroblasts or SK-MES-1 cells, with a phosphatidylinositol-specific phospholipase C(PI-PLC) significantly decreases specific HDL_3 binding. Moreover, PI-PLC treatment of cultured cells or cellular plasma membrane fractions results in releasing proteins. These proteins have a soluble form and can also bind HDL_3, as revealed by ligand blotting experiments with HDL_3. In order to obtain enriched GPI-proteins, we used a detergent-free purification method to prepare a caveolar membrane fraction. In the caveolar fraction, we obtained, by ligand blotting experiments, the enrichment of two HDL_3-binding proteins with molecular masses of 120 and 80 kDa. These proteins were also revealed in a plasma membrane preparation with two other proteins, with molecular masses of 150 and 104 kDa, and were sensitive to PI-PLC treatment. Electron microscopy also showed the binding of Au-labelled HDL_3 inside the vacuolar membrane invaginations. In SK-MES-1 cells, HDL_3 are internalized into a particular structure, resulting in the accumulation and concentration of such specific membrane domains. To sum up, a demonstration has been made of the implication of GPI-proteins as well as caveolae in the binding of HDL_3 to cells.

3.30 Reduction of protein disulfide bonds in an oxidizing environment

Majoul, I., Ferrari, D. and Soling, H-D.

*FEBS Lett., **401**, 104-108 (1997)*

Following retrograde transport to the endoplasmic reticulum (ER) the A-subunit of cholera toxin (CTX-A) is partially cleaved into CTX-A1 and CTX-A2 by reduction of a disulfide bridge [Majoul et al (1996) J. Cell Biol. 133, 777-789], although the redox state in the ER favors disulfide formation. We show here that the disulfide bridge of CTX-A is cleaved in vitro already at GSH/GSSG ratios between 1 and 3. Protein disulfide isomerase (PDI) exerts only a minor accelerating effect. Various mixed disulfide intermediates (CTX-A1-S-S-CTX-A1; PDI-S-S-A2; PDI-S-S-A1) appear during CTX-A reduction. These results indicate that in the ER protein disulfide formation and protein disulfide reduction can take place simultaneously.

3.31 Calbindin-D_{28k} in nerve cell nuclei

German, D.C., Ng, M.C., Liang, C.L., McMahon, A and Iacopino, A.M.

*Neurosci., **81(3)**, 735-743 (1997)*

Calbindin-D_{28k} is a member of the large EF-hand family of calcium-binding proteins that is believed to function, in part, as a cytosolic calcium buffer. Recent studies have demonstrated that cells containing Calbindin-D_{28k} are protected from degeneration caused by conditions that elevate intracellular calcium concentration. Since its initial discovery in 1966, Calbindin-D_{28k} has been localized in the cytoplasm of many neuronal populations, but its nuclear localization has been uncertain. Using light and electron microscopic immunochemistry, and nuclear fractionation methods, we demonstrate localization of Calbindin-D_{28k} not only in the cytoplasm, but also in the nucleus of rodent midbrain dopaminergic neurons and cerebellar Purkinje cells. The Calbindin-D_{28k} immunoreactive staining intensity in the nucleus was routinely equal or greater than that in the cytoplasm. Since calcium signals are propagated to the nucleus, where they can regulate gene expression, the existence of nuclear Calbindin-D_{28k} has important implications for cellular functions.

3.32 Membrane association of FtsY, the *E. coli* SRP receptor

DeLeeuw, et al

*FEBS Lett., **416**, 225-229 (1997)*

FtsY, the *Escherichia coli* homologue of the eukaryotic SRP receptor (SRα), is located both in the cytoplasm and in the inner membrane of *E. coli*. Similar to SRα, FtsY consists of the two major domains: a strongly acidic N-terminal domain (A) and a C-terminal GTP binding domain (NG) of which the crystal structure has recently been determined. The domains were expressed both in vivo and in vitro to examine their subcellular localization. The results suggest that both domains associated with the membrane but that the nature of the association differs.

3.33 Role for the target enzyme in deactivation of photoreceptor G protein in vivo
Tsang, S.H., et al**.**
*Science, **282(5386)**, 117-121(1998)*

Heterotrimeric guanosine 5'-triphosphate (GTP)-binding proteins (G proteins) are deactivated by hydrolysis of the GTP that they bind when activated by transmembrane receptors. Transducin, the G protein that relays visual excitation from rhodopsin to the cyclic guanosine 3', 5'-monophosphate phosphodiesterase (PDE) in retinal photoreceptors, must be deactivated for the light response to recover. A point mutation in the γ subunit of PDE impaired transducin-PDE interactions and slowed the recovery rate of the flash response in transgenic mouse rods. These results indicate that the normal deactivation of transducin in vivo requires the G protein to interact with its target enzyme.

3.34 Characterization of a cytosolic heat-shock protein-caveolin chaperone complex.
Uittenbogaard, A., Ying, Y.S. and Smart, E.J.
*J. Biol. Chem., **273(11)**, 6525-6532, (1998)*

Caveolin is a 22-kDa protein that appears to play a critical role in regulating the cholesterol concentration of caveolae. Even though caveolin is thought to be a membrane protein, several reports suggest that this peculiar protein can traffic independently of membrane vesicles. We now present evidence that a cytosolic pool of caveolin is part of a heat-shock protein-immunophilin chaperone complex consisting of caveolin, heat-shock protein 56, cyclophilin 40, cyclophilin A, and cholesterol. Treatment of NIH 3T3 cells with 1 μm cyclosporin A or 100 nm rapamycin disrupted the putative transport complex and prevented rapid (10-20 min) transport of cholesterol to caveolae. The lymphoid cell line, L1210-JF, does not express caveolin, does not form an immunophilin-caveolin complex, and does not transport newly synthesized cholesterol to caveolae. Transfection of caveolin cDNA into L1210-JF cells allowed the assembly of a transport complex identical to that found in NIH 3T3 cells. In addition, newly synthesized cholesterol in transfected cells was rapidly (10-20 min) and specifically transported to caveolae. These data strongly suggest that a caveolin-chaperone complex is a mechanism by which newly synthesized cholesterol is transported from the endoplasmic reticulum through the cytoplasm to caveolae.

3.35 Dissection of hepatic receptor-mediated endocytic pathways using self-generated gradients of iodixanol (OptiPrep).
Billington, D., Maltby, P.J. Jackson, A.P. and Graham, J.M.
*Anal. Biochem., **258**, 251-258 (1998).*

Iodixanol is a new, non-ionic, iodinated density gradient medium which has the advantage over other similar media in that it rapidly forms self-generated gradients in vertical or near-vertical rotors. Endocytosis of ^{99m}Tc-labelled neogalactosyl albumin (^{99m}Tc-NGA), a synthetic ligand for the asialoglycoprotein receptor, was studied by administering the ligand as a short pulse to perfused rat livers operating under single pass conditions. Intracellular processing was arrested at various times after the pulse and the resultant homogenate cleared of nuclei and heavy mitochondria by centrifugation at 3000g for 10 min. After adjusting to 12.5% (w/v) iodixanol, the 3000g supernatants were centrifuged at 350,000g for 60 min to form the gradients in which early, clathrin-containing vesicles, low-density endosomes and lysosomes were well-resolved. ^{99m}Tc-NGA bound to the sinusoidal membrane could be partially resolved from clathrin-containing vesicles by inclusion of 1 mM $CaCl_2$ in the homogenisation and gradient buffers. Two populations of early clathrin-containing vesicles could be resolved by rate-zonal centrifugation in pre-formed iodixanol gradients. Thus, iodixanol is an excellent density gradient medium for the rapid and efficient resolution of endosome compartments.

3.36 Subcellular distribution and turnover of presenilins in transfected cells.
Zhang, J. et al
*J. Biol. Chem., **273(20)**, 12436-12442 (1998)*

The mechanisms by which mutations in presenilin-1 (PS1) and presenilin-2 (PS2) result in the Alzheimer=s disease phenotype are unclear. Full-length PS1 and PS2 are each processed into stable proteolytic fragments after their biosynthesis in transfected cells. PS1 and PS2 have been localized by immunocytochemistry to the endoplasmic reticulum (ER) and Golgi compartments, but previous studies could not differentiate between the full-length presenilins and their fragments. Full-length PS1 and PS2 were principally distributed in ER fractions, whereas the N- and C-terminal fragments were localized predominantly to the Golgi fractions. In cells expressing the PS1 mutant lacking exon (ΔE9), we observed only full-length molecules that were present

in the ER and Golgi fractions. The turnover rate was considerably slower for the ΔE9 holoprotein, apparently due to decreased degradation within the ER. Our results suggest that full-length presenilin proteins are primarily ER resident molecules and undergo endoproteolysis within the ER. The fragments are subsequently transported to the Golgi compartment, where their turnover rate is much slower than that of the full-length presenilin in the ER.

3.37 Dietary fish oils modify the assembly of VLDL and expression of the LDL receptor in rabbit liver.
Wilkinson, J., Higgins, J.A., Fitzsimmons, C. and Bowyer, D.E.
*Arterioscler. Thromb. Vasc. Biol., **18**, 1490-1497 (1998)*

Supplementation of the diet of rabbits with fish oil or sunflower oil resulted in significant changes in the lipoproteins and lipids in serum. Compared with chow-fed rabbits, dietary fish oils decreased very low density lipoprotein (VLDL), increased low density lipoprotein (LDL), and shifted the peak of the LDL to denser fractions, whereas sunflower oil increased high density lipoprotein and shifted LDL to the lighter fractions. The amount of LDL receptors in fish oil-fed rabbit liver decreased by > 70% while there was only a small fall in these levels in sunflower oil-fed rabbit liver. The concentrations of apolipoprotein (apo) B in the subcellular organelles of the secretory compartment (rough and smooth endoplasmic reticula and Golgi fractions) were also changed by dietary lipids. In both sunflower oil- and fish oil-fed liver, apo B was increased in the lumen of the rough endoplasmic reticulum compared with fractions from chow-fed rabbit liver. The apo B in the trans-Golgi lumen from fish oil-fed livers was reduced and occurred in particles of $d \approx 1.21$ g/mL. In contrast, apo B in the trans-Golgi lumen from livers of sunflower oil-fed rabbits was increased and occurred in particles of $d < 1.21$ g/mL. These results suggests that feeding of fish oils causes an interruption in the intracellular transfer of apo B and hence assembly of VLDL. This leads to an enrichment of the rough endoplasmic reticulum membranes with cholesterol, thus down regulating the expression of the LDL receptor.

3.38 Phosphatidylinositol 4-phosphate synthesis in immunoisolated caveolae-like vesicles and low buoyant non-caveolar membranes.
Waugh, M.G., Lawson, D., Tan, S.K. and Hsuan, J.J.
*J. Biol. Chem., **273(27)**, 17115-17121 (1998)*

This study examined phosphatidylinositol 4-phosphate (PtdIns4P) synthesis in caveolae that have been suggested to be discrete signaling microdomains of the plasma membrane and are enriched in the marker protein caveolin. Caveolin-rich light membranes (CLMs) were isolated from A431 cells by detergent-free, discontinuous density-gradient centrifugation method. The CLM fraction was separated from the bulk of the cellular protein and was greatly enriched in PtdIns, PtdIns4P, and phosphatidylinositol 4,5-bisphosphate (PtdIns(4,5)P_2) and an adenosine-sensitive type II PtdIns 4-kinase activity. Preparation of CLMs by an **OptiPrep**-based cell fractionation procedure confirmed the co-localization of PtdIns 4-kinase and caveolin. Electron microscopy confirmed that an anti-caveolin antiserum immunopurified vesicles from CLMs that were within the size range described for caveolae in other systems. Co-immunoprecipitated PtdIns 4-kinase activity could utilize endogenous PtdIns, present within the caveolae and CLMs. However, less than 1% of the total cellular PtdIns and PtdIns 4-kinase activity was present in caveolae-like vesicles, indicating that non-caveolar light membranes rafts are the main sites for cellular PtdIns4P production.

3.39 Rapid enzyme-free preparation of starch-free nuclei from plants facilitates studies of chromatin structure.
Ford, T.C., Baldwin, J.P. and Lambert, S.J.
Plant proteins in abiotic stress responses, Plant Protein Club, 1998 Annual Symposium, University of York, p24 (1998)

Several studies of the chromatin structure of normal or stressed plant cells require rapid purification of the cell nuclei under conditions which do not alter the structure of the active or inactive genes under investigation. We have developed a very simple, rapid and enzyme-free method for preparing wheatgerm nuclei by centrifugation on an **iodixanol** step between densities 1.168 and 1.234 g/ml with a minimal contribution of the iodixanol to solution colligative properties (osmotic pressure). Histone octamers, which are key molecular complexes in the regulation of transcription and which are acetylated in specific lysines in active genes have been purified rapidly from the pure nuclei.

3.40 Insulin-induced protein tyrosine phosphorylation cascade and signalling molecules are localized in a caveolin-enriched cell membrane domain.
Smith, R.M., Harada, S., Smith, J.A., Zhang, S. and Jarett, L.
*Cell. Signalling, **10(5)**, 355-362 (1998)*

The cellular localisation of time- and temperature-dependent ^{125}I-insulin binding, insulin-sensitive signalling proteins and the insulin-induced protein tyrosine phosphorylation cascade were assessed in subcellular fractions isolated on **Iodixanol** gradients from control and insulin-treated H35 hepatoma cells. Western blot analysis demonstrated that the concentrations of IRS-1, Shc, GRB-2, SOS, Syp, PI 3-kinase, MAP kinase and $G_{1\alpha}$ were at least 10-fold higher in cell surface-derived, caveolin-enriched fraction than in a cell surface-derived, caveolin-poor fraction (i.e., the plasma membranes). Insulin treatment caused a 15-fold increase in tyrosine phosphorylation of IRS-1 in the caveolin-enriched fraction in 5 min at 37°C compared with a 3-fold increase in plasma membranes and a 6-fold increase in the cytosol and endosomes. Insulin also increased tyrosine phosphorylation of both a 72-kDa protein and the 46-kDa Shc isoform only in the caveolin-enriched fraction. Insulin treatment did not change the concentrations of insulin receptors or Shc but increased IRS-1 in the caveolin-enriched fraction, possibly recruited from the cytosolic pool. Insulin also increased the concentrations of insulin receptors, IRS-1 and Shc in endosomes, suggesting insulin-induced internalization of the insulin receptors and proteins activated with them. Electron microscopic analysis, with the use of a combination of colloidal gold-labelled insulin to label the insulin receptor and immunolabelling to detect caveolin or IRS-1, demonstrated the co-localisation of insulin receptors in caveolin- and IRS-1 containing vesicular structures. Differences in the insulin-induced protein tyrosine phosphorylation and concentrations of these proximal signalling proteins in the caveolin-enriched fraction, plasma membranes, and cytosol suggest that insulin receptors in the caveolae play a major role in the initiating insulin's signal transduction processes.

3.41 Purification and characterization of autophagosomes from rat hepatocytes.
Strømhaug, P.E., Berg, T.O.,
and Seglen, P.O.
*Biochem. J., **335**, 217-224 (1998)*

To investigate the properties and intracellular origin of autophagosomes, a procedure for the purification and isolation of these organelles from rat liver has been developed. Isolated hepatocytes were incubated with vinblastine to induce autophagosome accumulation; the cells were then homogenized and treated with the cathepsin C substrate glycyl-1-phenylalanine 2-naphthylamide to cause osmotic disruption of the lysosomes. Nuclei were removed by differential centrifugation, and the postnuclear supernatant was fractionated on a discontinuous Nycodenz density gradient. The autophagosomes, recognized by their content of autophagocytosed lactate dehydrogenase (LDH), could be recovered in an intermediated-density fraction, free from cytosol and mitochondria. Finally, the autophagosomes were separated from the endoplasmic reticulum and other membraneous elements by centrifugation in a Percoll colloidal density gradient, followed by flotation in **iodixanol** to remove the Percoll particles. The final autophagosome preparation represented a 24-fold purification of autophagocytosed LDH relative to intact cells, with a 12% recovery. The purified autophagosomes contained sequestered cytoplasm with a normal ultrastructure, including mitochondria, peroxisomes and endoplasmic reticulum in the same proportions as in intact cells. However, immunoblotting indicated a relative absence of cytoskeletal elements (tubulin, actin and cytokeratin), which may evade autophagic sequestration. The autophagosomes showed no enrichment in protein markers typical of lysosomes (acid phosphatase, cathepsin B, lysosomal glycoprotein of 120 kDa), endosomes (early-endosome-associated proteins 1, cation-independent mannose 6-phosphate-regulated protein of 78 kDa, protein disulphide isomerase), suggesting that the sequestering membranes are not derived directly from any of these organelles, but rather represent unique organelles (phagophores).

3.42 Presenilin 1 regulates the processing of β-amyloid precursor protein C-terminal fragments and the generation of amyloid β-protein in endoplasmic reticulum and Golgi.
Xia, W. et al
*Biochemistry, **37(47)**, 16465-71 (1998)*

Progressive cerebral deposition of the amyloid β-protein (Aβ) is believed to play a pivotal role in the pathogenesis of Alzheimer's disease (AD). The highly amyloidogenic 42-residue form of Aβ ($A\beta_{42}$) is the first species to be deposited in both sporadic and familial AD. Mutations in two familial AD-linked genes, presenilins 1 (PS1) and 2 (PS2), selectively increase the production of $A\beta_{42}$ in cultured cells and the brains of transgenic mice, and gene deletion of PS1 shows that it is required for normal gamma-secretase cleavage of the beta-amyloid precursor protein (APP) to generate Aβ. To establish the subcellular localization of the PS1

regulation of APP processing to Aβ, fibroblasts from PS1 wild-type (wt) or knockout (KO) embryos as well as Chinese hamster ovary (CHO) cells stably transfected with wt or mutant PS1 were subjected to subcellular fractionation on discontinuous **Iodixanol** gradients. APP C-terminal fragments (CTF) were markedly increased in both endoplasmic reticulum- (ER-) and Golgi-rich fractions of fibroblasts from KO mice; moreover, similar increases were documented directly in KO brain tissue. No change in the subcellular distribution of full-length APP was detectable in fibroblasts lacking PS1. In CHO cells, a small portion of APP, principally the N-glycosylated isoform, formed complexes with PS1 in both ER- and Golgi-rich fractions, as detected by coimmunoprecipitation. When the same fractions were analyzed by enzyme-linked immunosorbent assays for $A\beta_{total}$ and $A\beta_{42}$, $A\beta_{42}$ was the major Aβ species in the ER fraction ($A\beta_{42}$:$A\beta_{total}$ ratio 0.5-1.0), whereas absolute levels of both $A\beta_{42}$ and $A\beta_{40}$ were higher in the Golgi fraction and the $A\beta_{42}$:$A\beta_{total}$ ratio was 0.05-0.16 there. Mutant PS1 significantly increased $A\beta_{42}$ levels in the Golgi fraction. Our results indicate PS1 and APP can interact in the ER and Golgi, where PS1 is required for proper γ-secretase processing of APP CTFs, and that PS1 mutations augment $A\beta_{42}$ levels principally in Golgi-like vesicles.

3.43 Role of plasmalemmal caveolae in signal transduction

Shaul, P.W. and Anderson, R.G.W.
*Am. J. Physiol., **275**, 843-851 (1998)*

Caveolae are specialized plasmalemmal microdomains originally studied in numerous cell types for their involvement in the transcytosis of macromolecules. They are enriched in glycosphingolipids, cholesterol, sphingomyelin, and lipid-anchored membrane proteins, and they are characterized by a light buoyant density and resistance to solubilization by Triton X-100 at 4°C. Once the identification of the marker protein caveolin made it possible to purify this specialized membrane domain, it was discovered that caveolae also contain a variety of signal transduction molecules. This includes C protein-coupled receptors, G proteins and adenylyl cyclase, molecules involved in the regulation of intracellular calcium homeostasis, and their effectors including the endothelial isoform of nitric oxide synthase, multiple components of the tyrosine kinase-mitogen-activated protein kinase pathway, and numerous lipid signaling molecules. More recent work has indicated that caveolae further serve to compartmentalize, modulate, and integrate signaling events at the cell surface. This specialized plasmalemmal domain warrants direct consideration in future investigations of both normal and pathological signal transduction in pulmonary cell types.

3.44 Targeting of protein Kinase Cα to caveolae

Mineo, C., Ying, Y-S, Chapline, C., Jaken, S. and Anderson, R.G.W.
*J. Cell Biol., **141(3)**, 601-610 (1998)*

Previously, we showed caveolae contain a population of protein kinase Cα (PKCα) that appears to regulate membrane invagination. We now report that multiple PKC isoenzymes are enriched in caveolae of unstimulated fibroblasts. To understand the mechanism of PKC targeting, we prepared caveolae lacking PKCα and measured the interaction of recombinant PKCα with these membranes. PKCα bound with high affinity and specificity to caveolae membranes. Binding was calcium dependent, did not require addition of factors that activate the enzyme, and involved the regulatory domain of the molecule. A68-kD PKCα-binding protein identified as sdr (serum deprivation response) was isolated by interaction cloning and localized to caveolae. Antibodies against sdr inhibited PKCα binding. A 100-aminoacid sequence from the middle of sdr competitively blocked PKCα binding while flanking sequences were inactive. Caveolae appear to be a membrane site where PKC enzymes are organized to carry out essential regulatory functions as well as to modulate signal transduction at the cell surface.

3.45 SR-BII, an isoform of the scavenger receptor BI containing an alternate cytoplasmic tail, mediates lipid transfer between high density lipoprotein and cells

Webb, N.R. et al
*J. Biol. Chem., **273(24)**, 15241-15248 (1998)*

The scavenger receptor class B, type I (SR-BI), binds high density lipoprotein (HDL) and mediates selective uptake of cholesteryl ester from HDL and HDL-dependent cholesterol efflux from cells. We recently identified a new MRNA variant that differs from the previously characterized form in that the encoded C-terminal cytoplasmic domain is almost completely different. In the present study, we demonstrate that the mRNAs for mouse SR-El and SR-BII (previously termed SR-BI.2) are the

alternatively spliced products of a single gene. The translation products predicted from human, bovine, mouse, hamster, and rat cDNAs exhibit a high degree of sequence similarity within the SR-BII C-terminal domain (62-67% identity when compared with the human sequence), suggesting that this variant is biologically important. SR-BII protein represents approximately 12% of the total immunodetectable SR-BI/II protein in mouse liver. Subcellular fractionation of transfected Chinese hamster ovary cells showed that SR-BII, like SR-BI, is enriched in caveolae, indicating that the altered cytoplasmic tail does not affect targeting of the receptor. SR-BII mediated both selective cellular uptake of cholesteryl ether from HDL as well as HDL-dependent cholesterol efflux from cells, although with approximately 4-fold lower efficiency than SR-BI. *In vivo* studies using adenoviral vectors showed that SR-BII was relatively less efficient than SR-BI in reducing plasma HDL cholesterol. These studies show that SR-BII, an HDL receptor isoform containing a distinctly different cytoplasmic tail, mediates selective lipid transfer between HDL and cells, but with a lower efficiency than the previously characterized variant.

3.46 Cholesterol depletion of caveolae causes hyperactivation of extracellular signal-related kinase (ERK)
Furuchi, T. and Anderson, R.G.W.
J. Biol. Chem., ***273(33)****, 21009-21104 (1998)*

Previously we showed that activation of Erk in quiescent cells occurs in the caveolae fraction isolated from fibroblasts. Since the structure and function of caveolae is sensitive to the amount of cholesterol in the membrane, it might be that a direct link exists between the concentration of membrane cholesterol and mitogen activated protein (MAP) kinase activation. We acutely lowered the cholesterol level of the caveolae fraction by incubating Rat-1 cells in the presence of either cyclodextrin or progesterone. Cholesterol-depleted caveolae had a reduced amount of several key protein components of the MAP kinase complex, including Ras, Grb2, Erk2, and Src. Incubation of these cells in the presence of epidermal growth factor (EGF) caused a rapid loss of EGF receptor from the caveolae fraction, but the usual recruitment of c-Raf was markedly inhibited. Despite the reduced amount of c-Raf and Erk2 in the cholesterol depleted caveolae fraction, EGF caused a hyperactivation of the remaining caveolae Erk isoenzymes. This was followed by an increase in the amount of active Erk in the cytoplasm. The increased amount of activated Erk produced under these conditions was linked to a 2-fold higher level of EGF-stimulated DNA synthesis. Even cholesterol depletion by itself stimulated Erk activation and DNA synthesis. These results suggest that the MAP kinase pathway can connect the cholesterol level of caveolae membrane to the control of cell division.

3.47 Sec6/8 complex is recruited to cell-cell contacts and specifies transport vesicle delivery to the basal-lateral membrane in epithelial cells
Grindstaff, K.K., Yeaman, C., Anandasabapathy, N., Hsu, S.C., Rodriguez-Boulan,E., Scheller R.H. and Nelson, W.J.
Cell, ***93****, 731-740 (1998)*

In budding yeast, the Sec6/8p complex is essential for generating cell polarity by specifying vesicle delivery to the bud tip. We show that Sec6/8 homologs are components of a cytosolic, ~17S complex in nonpolarized MDCK epithelial cells. Upon initiation of calcium-dependent cell-cell adhesion, ~70% of Sec6/8 is rapidly ($t_{1/2} \approx$ 3-6 hr) recruited to sites of cell-cell contact. In streptolyslin-O-permeabilized MDCK cells, Sec6/8 antibodies inhibit delivery of LDL receptor to the basal-lateral membrane, but not $p75^{NTR}$ to the apical membrane. These results indicate that lateral membrane recruitment of the Sec6/8 complex is a consequence of cell-cell adhesion and is essential for the biogenesis of epithelial cell surface polarity.

3.48 ARNO is a guanine nucleotide exchange factor for ADP-ribosylation factor 6
Frank, S., Upender, S., Hansen, S.H. and Casanova, J.E.
J. Biol. Chem., ***273(1)****, 23-27(1998)*

ADP-ribosylation factors (ARFS) constitute a family of small monomeric GTPases. ARFs 1 and 3 function in the recruitment of coat proteins to membranes of the Golgi apparatus, whereas ARF6 is localized to the plasma membrane, where it appears to modulate both the assembly of the actin cytoskeleton and endocytosis. Like other GTPases, ARF activation is facilitated by specific guanine nucleotide exchange factors (GEFs). ARNO (ARF nucleotide-binding site opener) is a member of a growing family of ARF-GEFs that share a common, tripartite structure consisting of an N-terminal coiled-coil domain, a central domain with homology to the yeast protein Sec7p, and a C-terminal pleckstrin homology domain. Recently, ARNO and its close homologue cytohesin-1 were found to catalyze *in vitro*

nucleotide exchange on ARF1 and ARF3, respectively, raising the possibility that these GEFs function in the Golgi. However, the actual function of these proteins may be determined in part by their ability to interact with specific ARFs and in part by their subcellular localization. We report here that *in vitro* ARNO can stimulate nucleotide exchange on both ARF1 and ARF6. Furthermore, based on subcellular fractionation and immunolocalization experiments, we find that ARNO is localized to the plasma membrane in mammalian cells rather than the Golgi. It is therefore likely that ARNO functions in plasma membrane events by modulating the activity of ARF6 *in vivo*. These findings are consistent with the previous observation that cytohesin-1 regulates the adhesiveness of $\alpha L\beta_2$ integrins at the plasma membrane of lymphocytes.

3.49 Retrograde transport of Golgi-localized proteins to the ER
Cole, N.B., Ellenberg, J., Song, J., DiEuliis, D. and Lippincott-Schwarz, J.
J. Cell Biol., ***140(1)****, 1-15 (1998)*

Abstract. The ER is uniquely enriched in chaperones and folding enzymes that facilitate folding and unfolding reactions and ensure that only correctly folded and assembled proteins leave this compartment. Here we address the extent to which proteins that leave the ER and localize to distal sites in the secretary pathway are able to return to the ER folding environment during their lifetime. Retrieval of proteins back to the ER was studied using an assay based on the capacity of the ER to retain misfolded proteins. The lumenal domain of the temperature-sensitive viral glycoprotein VSVGtsO45 was fused to Golgi or plasma membrane targeting domains. At the nonpermissive temperature, newly synthesized fusion proteins misfolded and were retained in the ER, indicating the VSVGtsO45 ectodomain was sufficient for their retention within the ER. At the permissive temperature, the fusion proteins were correctly delivered to the Golgi complex or plasma membrane, indicating the lumenal epitope of VSVGtsO45 also did not interfere with proper targeting of these molecules. Strikingly, Golgi-localized fusion proteins, but not VSVGtsO45 itself, were found to redistribute back to the ER upon a shift to the nonpermissive temperature, where they misfolded and were retained. This occurred over a time period of 15 min-2 h depending on the chimera, and did not require new protein synthesis. Significantly, recycling did not appear to be induced by misfolding of the chimeras within the Golgi complex. This suggested these proteins normally cycle between the Golgi and ER, and while passing through the ER at 40°C become misfolded and retained. The attachment of the thermosensitive VSVGtsO45 lumenal domain to proteins promises to be a useful tool for studying the molecular mechanisms and specificity of retrograde traffic to the ER.

3.50 Isolation of functional Golgi-derived vesicles with a possible role in retrograde transport
Love, H.D., Lin, C.C., Short, C.S. and Ostermann, J.
J. Cell Biol., ***140(3)****, 541-551 (1998)*

Secretory proteins enter the Golgi apparatus when transport vesicles fuse with the *cis* -side and exit in transport vesicles budding from the *trans*-side. Resident Golgi enzymes that have been transported in the *cis-to-trans* direction with the secretary flow must be recycled constantly by retrograde transport in the opposite direction. In this study, we describe the functional characterization of Golgi-derived transport vesicles that were isolated from tissue culture cells. We found that under the steady-state conditions of a living cell, a fraction of resident Golgi enzymes was found in vesicles that could be separated from cistemal membranes. These vesicles appeared to be depleted of secretary cargo. They were capable of binding to and fusion with isolated Golgi membranes, and after fusion their enzymatic contents most efficiently processed cargo that had just entered the Golgi apparatus. Those results indicate a possible role for these structures in recycling of Golgi enzymes in the Golgi stack.

3.51 Caveolin-1 and –2 in the exocytic pathway of MDCK cells
Scheiffele, P. et al
J. Cell Biol., ***140(4)****, 795-806 (1998)*

Abstract. We have studied the biosynthesis and transport of the endogenous caveolins in MDCK cells. We show that in addition to homooligomers of caveolin-1, heterooligomeric complexes of caveolin-1 and -2 are formed in the ER. The oligomers become larger, increasingly detergent insoluble, and phosphorylated on caveolin-2 during transport to the cell surface. In the TGN caveolin-l/-2 heterooligomers are sorted into basolateral vesicles, whereas larger caveolin-I homooligomers are targeted to the apical side. Caveolin-1 is present on both the apical and basolateral plasma membrane, whereas caveolin-2 is enriched on the basolateral surface where caveolae are present. This suggests that caveolin-1 and -2 heterooligomers are involved in caveolar biogenesis in the basolateral plasma membrane. Anti-

caveolin-1 antibodies inhibit the apical delivery of influenza virus hemagglutinin without affecting basolateral transport of vesicular stomatitis virus G protein. Thus, we suggest that caveolin-1 homooligomers play a role in apical transport.

3.52 Caveolae, plasma membrane microdomains for α-secretase-mediated processing of the amyloid precursor protein

Ikezu, T et al

*J. Biol. Chem., **273(17)**, 10485-10495 (1998)*

Caveolae are plasma membrane invaginations where key signaling elements are concentrated. In this report, both biochemical and histochemical analyses demonstrate that the amyloid precursor protein (APP), a source of Aβ amyloid peptide, is enriched within caveolae. Caveolin-1, a principal component of caveolae, is physically associated with APP, and the cytoplasmic domain of APP directly participates in this binding. The characteristic C-terminal fragment that results from APP processing by α-secretase, an as yet unidentified enzyme that cleaves APP within the Aβ amyloid sequence, was also localized within these caveolae-enriched fractions. Further analysis by cell surface biotinylation revealed that this cleavage event occurs at the cell surface. Importantly, α-secretase processing was significantly promoted by recombinant overexpression of caveolin in intact cells, resulting in increased secretion of the soluble extracellular domain of APP. Conversely, caveolin depletion using antisense oligonucleotides prevented this cleavage event. Our current results indicate that caveolae and caveolins may play a pivotal role in the α-secretase-mediated proteolysis of APP in *vivo.*

3.53 Lipid domain structure of the plasma membrane revealed by patching of membrane components

Harder, T., Scheiffele, P., Verkade, P. and Simons K.

*J. Cell Biol., **141(4)**, 929-942 (1998)*

Abstract. Lateral assemblies of glycolipids and cholesterol, "rafts," have been implicated to play a role in cellular processes like membrane sorting, signal transduction, and cell adhesion. We studied the structure of raft domains in the plasma membrane of non-polarized cells. Overexpressed plasma membrane markers were evenly distributed in the plasma membrane. We compared the patching behavior of pairs of raft markers (defined by insolubility in Triton X-100) with pairs of raft/non-raft markers. For this purpose we cross-linked glycosyl-phosphatidylinositol (GPI)-anchored proteins placental alkaline phosphatase (PLAP), Thy-1, influenza virus hemagglutinin (HA), and the raft lipid ganglioside GM1 using antibodies and/or cholera toxin. The patches of these raft markers overlapped extensively in BHK cells as well as in Jurkat T-lymphoma cells. Importantly, patches of GPI-anchored PLAP accumulated src-like protein tyrosine kinase fyn, which is thought to be anchored in the cytoplasmic leaflet of raft domains. In contrast patched raft components and patches of transferrin receptor as a non-raft marker were sharply separated. Taken together, our data strongly suggest that coalescence of cross-linked raft elements is mediated by their common lipid environments, whereas separation of raft and non-raft patches is caused by the immiscibility of different lipid phases. This view is supported by the finding that cholesterol depletion abrogated segregation. Our results are consistent with the view that raft domains in the plasma membrane of non-polarized cells are normally small and highly dispersed but that raft size can be modulated by oligomerization of raft components.

3.54 Cholesterol depletion inhibits the generation of β-amyloid in hippocampal neurons

Simons, M., Keller, P., De Strooper, B., Beyreuther, K., Dotti, C.G. and Simons, K.

*Proc. Natl. Acad. Sci. USA, **95**, 6460-6464 (1998)*

The amyloid precursor protein (APP) plays a crucial role in the pathogenesis of Alzheimer's disease. During intracellular transport APP undergoes a series of proteolytic cleavages that lead to the release either of an amyloidogenic fragment called β-amyloid (Aβ) or of a nonamyloidogenic secreted form consisting of the ectodomain of APP (APP_{sec}). It is Aβ that accumulates in the brain lesions that are thought to cause the disease. By reducing the cellular cholesterol level of living hippocampal neurons by 70% with lovastatin and methyl-β-cyclodextrin, we show that the formation of Aβ is completely inhibited while the generation of APP_{sec} is unperturbed. This inhibition of Aβ formation is accompanied by increased solubility in the detergent Triton X-100 and is fully reversible by the readdition of cholesterol to previously depleted cells. Our results show that cholesterol is required for Aβ formation to occur and imply a link between cholesterol, Aβ, and Alzheimer's disease.

3.55 CD14-dependent endotoxin internalization via a macropinocytic pathway

Poussin, C., Foti, M., Carpentier, J.L. and Pugin, J.
J. Biol. Chem., ***273(32)****, 20285-20291 (1998)*

Gram-negative bacterial endotoxin (a lipopolysaccharide (LPS)) specifically binds to CD14, a glycosylphosphatidyl inositol (GPI)-anchored surface myeloid glycoprotein. This interaction leads to cell activation, but it also promotes LPS internalization and detoxification. In this work, we investigated the route of LPS and CD14 internalization and the relevance of CD14 GPI anchor in the endocytic pathway. In promonocytic THP-1 ells transfected with a GPI or a chimeric integral form of CD14, we showed by differential buoyancy 'm sucrose density gradients that these two forms of CD14 were sorted to different plasma membrane subdomains. However, both forms of CD14 associated preferentially with the same surface microfilament-enriched microvilli or ruffles. Electron microscopic studies indicated that CD14 internalized via macropinocytosis, a process resembling that of phagocytosis, different from "classical" receptor-mediated endocytic pathways, such as clathrin-coated pits or caveolae. With cell warming, the CD14-enriched ruffles fused and formed large vesicles. Later, these vacuoles made stacks and condensed into phago-lysosomes. CD14 was specifically associated with all of these structures. Radiolabeled LPS internalization paralleled CD14 internalization. Confocal microscopic studies confirmed the co-localization of LPS and CD14 both at the cell surface and in endosomal compartments. The microfilament-disrupting, macropinocytosis blocking agent cytochalasin D inhibited LPS and CD14 internalization but did not prevent LPS-dependent activation, indicating that these two processes are dissociated.

3.56 Isolation and characterization of rat liver amphisomes

Berg, T.O., Fengsrud, M., Stromhaug, P.E., Berg, T. and Seglen, P.O.
J. Biol. Chem., ***273(34)****, 21883-21892 (1998)*

Amphisomes, the autophagic vacuoles (AVs) formed upon fusion between autophagosomes and endosomes, have so far only been characterized in indirect, functional terms. To enable a physical distinction between autophagosomes and amphisomes, the latter were selectively density-shifted in sucrose gradients following fusion with AOM-gold-loaded endosomes (endosomes made dense by asialoorosomucoid-conjugated gold particles, endocytosed by isolated rat hepatocytes prior to subcellular fractionation). Whereas amphisomes, by this criterion, accounted for only a minor fraction of the AVs in control hepatocytes, treatment of the cells with leupeptin (an inhibitor of lysosomal protein degradation) caused an accumulation of amphisomes to about one-half of the " population. A quantitative electron microscopic study confirmed that leupeptin induced a severalfold increase in the number of hepatocytic amphisomes (recognized by their gold particle contents; otherwise, their ultrastructure was quite similar to antophagosomes). Leupeptin caused, furthermore, a selective retention of endocytosed AOM-gold in the amphisomes at the expense of the lysosomes, consistent with an inhibition of amphisome-lysosome fusion. The electron micrographs suggested that autophagosomes could undergo multiple independent fusions, with multivesicular (late) endosomes to form amphisomes and with small lysosomes to form large autolysosomes. A biochemical comparison between autophagosomes and amphisomes, purified by a novel procedure, showed that the amphisomes were enriched in early endosome markers (the asialoglycoprotein receptor and the early endosome-associated protein 1) as well as in a late endosome marker (the cation-independent mannose 6-phosphate receptor). Amphisomes would thus seem to be capable of receiving inputs both from early and late endosomes.

3.57 Apg14p and Apg6/Vps30p form a protein complex essential for autophagy in the yeast *Saccharomyces cerevisiae*

Kametaka, S., Okano, T., Ohsumi, M. and Ohsumi, Y.
J. Biol. Chem., ***273(35)****, 22284-22291 (1998)*

Mutation in the *Saccharomyces cerevisiae APG14* gene causes a defect in autophagy. Cloning and structural analysis of the APG14 gene revealed that APG14 encodes a novel hydrophilic protein with a predicted molecular mass of 40.5 kDa, and that Apgl4p has a coiled-coil motif at its N terminus region. We found that overproduction of Apgl4p partially reversed the defect in autophagy induced by the *apg6-1* mutation. The *apg6-1* mutant was found to be defective not only in autophagy but also in sorting of carboxypeptidase Y (CPY), a vacuolar-soluble hydrolase, to the vacuole. However, overexpression of *APG14* did not alter the CPY sorting defect of the *apg6-l* mutant, nor did the *apgl4* null mutation affect the CPY sorting pathway. Structural analysis of *APG6* revealed that *APG6* is identical to *VPS30*, which is involved in a retrieval step of the CPY receptor, Vpsl0p, to the late Golgi from the endosome (Seaman, M. N. J., Marcusson, E. G., Cereghino, J. L., and Emr, S. D. (1997) *J. Cell Biol* 137, 79-92). Subcellular

fractionation indicated that Apgl4p and Apg6p peripherally associated with a membrane structure(s). Apgl4p was co-immunoprecipitated with Apg6p, suggesting that they form a stable protein complex. These results imply that Apg6/Vps30p has two distinct functions in the autophagic process and the vacuolar protein sorting pathway. Apgl4p may be a component specifically required for the function of Apg6/Vps30p through the autophagic pathway.

3.58 Annexin XIIIb associates with lipid microdomains to function in apical delivery
Lafont, F., Lecat, S., Verkade, P. and Simons K.
J. Cell Biol., ***142(6)***, *1413-1427 (1998)*

A member of the annexin XIII sub-family, annexin XIIIb, has been implicated in the apical exocytosis of epithelial kidney cells. Annexins are phospholipid-binding proteins that have been suggested to be involved in membrane trafficking events although their actual physiological function remains open. Unlike the other annexins, annexin XIIIs are myristoylated. Here, we show by immunoelectron microscopy that annexin XIIIb is localized to the *trans*-Golgi network (TGN), vesicular carriers and the apical cell surface. Polarized apical sorting involves clustering of apical proteins into dynamic sphingolipid-cholesterol rafts. We now provide evidence for the raft association of annexin XIIIb. Using in vitro assays and either myristoylated or unmyristoylated recombinant annexin XIIIb, we demonstrate that annexin XIIIb in its native myristoylated form stimulates specifically apical transport whereas the unmyristoylated form inhibits this route. Moreover, we show that formation of apical carriers from the TGN is inhibited by an anti-annexin XIIIb antibody whereas it is stimulated by myristoylated recombinant annexin XIIIb. These results suggest that annexin XIIIb directly participates in apical delivery.

3.59 The *Escherichia coli* SRP and SecB targeting pathways converge at the translocon
Valent, Q.A. et al
The EMBO J., ***17(9)***, *2504-2512 (1998)*

Two distinct protein targeting pathways can direct proteins to the *Escherichia coli* inner membrane. The Sec pathway involves the cytosolic chaperone SecB that binds to the mature region of pre-proteins. SecB targets the pre-protein to SecA that mediates preprotein translocation through the SecYEG translocon. The SRP pathway is probably used primarily for the targeting and assembly of inner membrane proteins. It involves the signal recognition particle (SRP) that interacts with the hydrophobic targeting signal of nascent proteins. By using a protein cross-linking approach, we demonstrate here that the SRP pathway delivers nascent inner membrane proteins at the membrane. The SRP receptor FtsY, GTP and inner membranes are required for release of the nascent proteins from the SRP. Upon release of the SRP at the membrane, the targeted nascent proteins insert into a translocon that contains at least SecA, SecY and SecG. Hence, as appears to be the case for several other translocation systems, multiple targeting mechanisms deliver a variety of precursor proteins to a common membrane translocation complex of the *E.coli* inner membrane.

3.60 Functions of lipid rafts in biological membranes
Brown, D.A. and London, E.
Annu. Rev. Cell Dev. Biol., ***14***, *111-136 (1998)*

Recent studies showing that detergent-resistant membrane fragments can be isolated from cells suggest that biological membranes are not always in a liquid-crystalline phase. Instead, sphingolipid and cholesterol-rich membranes such as plasma membranes appear to exist, at least partially, in the liquid-ordered phase or a phase with similar properties. Sphingolipid and cholesterol-rich domains may exist as phase-separated “rafts” in the membrane. We discuss the relationship between detergent-resistant membranes, rafts, caveolae, and low-density plasma membrane fragments. We also discuss possible functions of lipid rafts in membranes. Signal transduction through the high-affinity receptor for IgE on basophils, and possibly through related receptors on other hematopoietic cells, appears to be enhanced by association with rafts. Raft association may also aid in signaling through proteins anchored by glycosylphosphatidylinositol, particularly in hematopoietic cells and neurons. Rafts may also function in sorting and trafficking through the secretary and endocytic pathways.

3.61 The calcium-sensing receptor is localized in caveolin-rich plasma membrane domains of bovine parathyroid cells

Kifor, O., Diaz, R., Butters, R., Kifor, I. And Brown, E.M.

J. Biol. Chem., ***273(34)****, 21708-21713 (1998)*

Parathyroid cells have an intracellular machinery for parathyroid hormone (PTH) secretion that is inversely regulated by the extracellular calcium concentration (Ca^{2+}_o). The recently characterized Ca^{2+}_o sensing receptor (CaR) is a G protein-coupled, seven-transmembrane receptor mediating the inhibitory effects of high Ca^{2+}_o on PTH secretion. The CaR's precise cell surface localization and the signal transduction pathway(s) mediating its inhibitory effects on PTH secretion have not been characterized fully. Here, we demonstrate that the CaR resides within caveolin-rich membrane domains in bovine parathyroid cells. Chief cells within bovine parathyroid glands exhibit a similar pattern of staining for caveolin-1 and for alkaline phosphatase, a glucosylphosphatidyl-inositol-anchored protein often enriched in caveolae. Purified caveolin-enriched membrane fractions (CEMF) from bovine parathyroid cells are highly enriched in the CaR and alkaline phosphatase. Other signaling proteins, including $G_{q/11}$, ENOS, and several protein kinase C isoforms (i.e. α, δ, and ζ) are also present in CEMF. Activation of the CaR by high Ca^{2+}_o increases tyrosine phosphorylation of caveolin-1 in CEMF, suggesting that CaR-mediated signal transduction potentially involved in Ca^{2+}_o regulated processes in parathyroid cells occur in caveolae-like domains.

3.62 Palmitoylation of Neurofascin at a Site in the Membrane-Spanning Domain Highly Conserved Among the L1 Family of Cell Adhesion Molecules

Ren, Q. and Bennett, V.

J. Neurochem., ***70(5)****, 1839-1849 (1998)*

This report presents the first evidence that a member of the L1 family of nervous system cell-adhesion molecules is covalently modified by thioesterification with palmitate, and identifies a highly conserved cysteine in the predicted membrane-spanning domain as the site of modification. Neurofascin is constitutively palmitoylated at cysteine-1213 at close to a 1:1 molar stoichiometry. Kinetics of palmitate incorporation into neurofascin expressed in resting neuroblastoma cells indicate that the palmitate modification has the same turnover rate as the polypeptide chain and does not affect the protein stability of neurofascin. Palmitoylation of neurofascin expressed in dorsal root ganglion neurons is not required for delivery of neurofascin to the plasma membrane or targeting to axons. Palmitoylation also has no effect on ankyrin-binding activity of neurofascin, on the oligomeric state of neurofascin in solution, or on cell-adhesion activity of neurofascin expressed in neuroblastoma cells. A significant difference between native and C1213L neurofascin is that these proteins were localized in distinct fractions within a low-density membrane population enriched in signaling molecules. These results indicate a palmitate-dependent targeting of neurofascin to a specialized membrane microdomain.

3.63 The receptor recycling pathway contains two distinct populations of early endosomes with different sorting functions.

Sheff, D.R., Daro, E.A., Hull, M. and Mellmann, I.

J. Cell Biol., ***145(1),*** *123-139 (1999)*

Receptor recycling involves two endosome populations, peripheral early endosomes and perinuclear recycling endosomes. In polarized epithelial cells, either or both populations must be able to sort apical from basolateral proteins, returning each to its appropriate plasma membrane domain. However, neither the roles of early versus recycling endosomes in polarity nor their relationship to each other has been quantitatively evaluated. Using a combined morphological, biochemical, and kinetic approach, we found these two endosome populations to represent physically and functionally distinct compartments. Early and recycling endosomes were resolved on **Optiprep** gradients and shown to be differentially associated with rab4, rab11, and transferrin receptor; rab4 was enriched on early endosomes and at least partially depleted from recycling endosomes, with the opposite being true for rab11 and transferrin receptor. The two populations were also pharmacologically distinct, with AlF_4 selectively blocking export of transferrin receptor from recycling endosomes to the basolateral plasma membrane. We applied these observations to a detailed kinetic analysis of transferrin and dimeric IgA recycling and transcytosis. The data from these experiments permitted the construction of a testable, mathematical model which enabled a dissection of the roles of early and recycling endosomes in polarized receptor transport. Contrary to expectations, the majority (>65%) of recycling to the basolateral surface is likely to occur from early endosomes, but with relatively little sorting of apical from

basolateral proteins. Instead, more complete segregation of basolateral receptors from receptors intended for transcytosis occurred upon delivery to recycling endosomes.

3.64 Opposing effects of reactive oxygen species and cholesterol on endothelial nitric oxide synthase and endothelial cell caveolae.
Peterson, T.E. et al.
*Circulation Res., **85**, 29-37 (1999)*

Synthesis of nitric oxide (NO) by endothelial nitric oxide synthase (eNOS) is critical for normal vascular home-ostasis. eNOS function is rapidly regulated by agonists and blood flow and chronically by factors that regulate mRNA stability and gene transcription. Recently, localization of eNOS to specialized plasma membrane invagin-ations termed caveolae has been proposed to be required for maximal eNOS activity. Because caveolae are highly enriched in cholesterol, and hypercholesterolemia is associated with increased NO production, we first studied the effects of cholesterol loading on eNOS localization and NO production in cultured bovine aortic endothelial cells (BAECs). Caveolae-enriched fractions were prepared by OptiPrep gradient density centrifug-ation. Treatment of BAECs with 30 μg/mL cholesterol for 24 hours stimulated significant increases in total eNOS protein expression (1.50-fold), eNOS associated with caveolae-enriched membranes (2.23-fold), and calcium ionophore-stimulated NO production (1.56-fold). Because reactive oxygen species (ROS) contribute to endothelial dysfunction in hypercholesterolemia, we next studied the effects of ROS on eNOS localization and caveolae number. Treatment of BAECs for 24 hours with 1 μmol/L LY83583, a superoxide-generating naptho-quinolinedione, decreased caveolae number measured by electron microscopy and prevented the cholesterol-mediated increases in eNOS expression. In vitro exposure of caveolae-enriched membranes to ROS (xanthine + xanthine oxidase) dissociated caveolin more readily than eNOS from the membranes. These results show that cholesterol treatment increases eNOS expression, whereas ROS treatment decreases eNOS expression and the association of eNOS with caveolin in caveolae-enriched membranes. Our data suggest that oxidative stress modulates endothelial function by regulating caveolae formation, eNOS expression, and eNOS-caveolin interactions.

3.65 Purification and characterization of rat hippocamal CA3-dendritic spines associated with mossy fiber terminals
Kiebler, M.A., Lopez-Garcia, J.C. and Leopold, P.L.
*FEBS Lett., **445**, 80-86 (1999)*

We report a revised and improved isolation procedure for CA3-dendritic spines, most of them still in association with mossy fiber terminals resulting in a 7.5-fold enrichment over nuclei and a 29-fold enrichment over myelin. Additionally, red blood cells, medullated fibers, mitochondria and small synaptosomes were significantly depleted. We show by high resolution electron microscopy that this subcellular fraction contains numerous dendritic spines with a rich ultrastructure, e.g. an intact spine apparatus, membranous organelles, free and membrane-bound polyribosomes, endocytic structures and mitochondria. This improved experimental system will allow us to study aspects of post-synaptic functions at the biochemical and molecular level.

3.66 Separation of the intracellular secretory compartment of rat liver and isolated rat hepatocytes in a single step using self-generating gradients of iodixanol
Plonne, D., Cartwright, I., Linss, W., Dargel, R., Graham, J.M. and Higgins, J.A.*Anal. Biochem., **276(1)**, 88-96 (1999)*

A novel method is described for the separation on a single gradient of the major intracellular organelles of the secretory pathway, the Golgi, the smooth endoplasmic reticulum (ER), and the rough (ER). Total microsomes were prepared from rat liver by differential centrifugation and resuspended in 20% **iodixanol**. The microsomal suspension was then layered between a 30% iodixanol cushion and a layer of 15% iodixanol and centrifuged in a vertical rotor for 2 h. The microsomes distributed in four visible bands. The gradients were collected by upward displacement and were characterized (i) by determination of UDP galactose-galactosyl-transferase (Golgi marker) NADPH-cytochrome c reductase (ER marker) and RNA (rough endoplasmic reticulum marker); (ii) by immunoblotting for TGN38 (*trans*-Golgi marker) and GS28 (*cis*-Golgi marker) and for protein disulfide isomerase (endoplasmic reticulum lumenal marker); (iii) by determination of the lipid composition; and (iv) by electron microscopy. The results suggest that the top band (density 1.045-1.090 g/ml), which contains 68% of the galactosyltransferase activity, consists of vesicles derived from the Golgi. The second broad band in the middle of the tube (density 1.130-1.160 g/ml), which contains 54% of the NADPH-cytochrome c reductase activity, consists mainly of vesicles derived from the smooth endoplasmic reticulum, overlapped at the top by a small band of Golgi-derived lamellae. The two bands at the bottom of the tube

(density 1.130-1.160 and density 1.180-1.220 g/ml) appear to contain two subfractions of vesicles derived from the rough endoplasmic reticulum.

3.67 Raft association of SNAP receptors acting in apical trafficking in Madin-Darby canine kidney cells
Lafont, F., Verkade, P., Galli, T., Wimmer, C., Louvard, D. and Simons, K.
*Proc. Natl. Acad. Sci. USA, **96**, 3734-3738 (1999)*

We have investigated the relationship between apical sorting mechanism using lipid rafts and the soluble N-ethyl maleimide-sensitive factor attachment protein receptor (SNARE) machinery, which is involved in membrane docking and fusion. We first confirmed that anti-alpha-SNAP antibodies inhibit the apical pathway in Madin-Darby canine kidney (MDCK) cells; in addition, we report that a recombinant SNAP mutant inhibits this transport step. Based on t-SNARE overexpression experiments and the effect of botulinum neurotoxin E, syntaxin 3 and SNAP-23 have been implicated in apical membrane trafficking. Here, we show in permeabilized MDCK cells that antisyntaxin 3 and anti-SNAP-23 antibodies lower surface delivery of an apical reporter protein. Moreover, using a similar approach, we show that tetanus toxin-insensitive, vesicle-associated membrane protein (TI-VAMP; also called VAMP7), a recently described apical v-SNARE, is involved. Furthermore, we show the presence of syntaxin 3 and TI-VAMP in isolated apical carriers. Polarized apical sorting has been postulated to be mediated by the clustering of apical proteins into dynamic sphingolipid-cholesterol rafts. We provide evidence that syntaxin 3 and TI-VAMP are raft-associated. These data support a raft-based mechanism for the sorting of not only apically destined cargo but also of SNAREs having functions in apical membrane-docking and fusion events.

3.68 Analysis of CD44-containing lipid rafts: Recruitment of Annexin II and stabilization by the actin cytoskeleton
Oliferenko, S., et al
*J. Cell Biol., **146(4)**, 843-854 (1999)*

CD44, the major cell surface receptor for hyaluronic acid (HA), was shown to localize to detergent-resistant cholesterol-rich microdomains, called lipid rafts, in fibroblasts and blood cells. Here, we have investigated the molecular environment of CD44 within the plane of the basolateral membrane of polarized mammary epithelial cells. We show that CD44 partitions into lipid rafts that contain annexin II at their cytoplasmic face. Both CD44 and annexin II were released from these lipid rafts by sequestration of plasma membrane cholesterol. Partition of annexin II and CD44 to the same type of lipid rafts was demonstrated by cross-linking experiments in living cells. First, when CD44 was clustered at the cell surface by anti-CD44 antibodies, annexin II was recruited into the cytoplasmic leaflet of CD44 clusters. Second, the formation of intracellular, submembranous annexin II-p11 aggregates caused by expression of a trans-dominant mutant of annexin II resulted in coclustering of CD44. Moreover, a frequent redirection of actin bundles to these clusters was observed. These basolateral CD44/annexin II-lipid raft complexes were stabilized by addition of GTPγS or phalloidin in a semipermeabilized and cholesterol depleted cell system. The low lateral mobility of CD44 in the plasma membrane, as assessed with fluorescent recovery after photobleaching (FRAP), was dependent on the presence of plasma membrane cholesterol and an intact actin cytoskeleton. Disruption of the actin cytoskeleton dramatically increased the fraction of CD44 which could be recovered from the light detergent-insoluble membrane fraction. Taken together, our data indicate that in mammary epithelial cells the vast majority of CD44 interacts with annexin II in lipid rafts in a cholesterol-dependent manner. These CD44-containing lipid microdomains interact with the underlying actin cytoskeleton.

3.69 Subcellular distribution of tuberin in cells derived from brain and liver
Yamamoto, Y. and Yeung, R.S.
*Proc. Amer. Assoc. Cancer Res., **40**, #4515 (1999)*

Mutations of TSC1 and TSC2 are responsible for the autosomal syndrome of tuberous sclerosis which predisposes carriers to the development of hamartomas and neoplasia. The TSC2 product, tuberin, possesses tumor suppressor activity and *in vitro* GAP activity towards Rap1 and Rab5. However, the physiological function of tuberin remains poorly understood. Primary sequence analysis suggested a putative transmembrane domain consistent with its abundance in the P100 post nuclear fraction and indirect immunofluorescence demonstrated co-localization with Rap1 and other Golgi markers. In light of the potential role of tuberin in the vesicular trafficking, we studied its subcellular distribution in cells of primary tissues using biochemical fractionation. Microsomal fractions of rat brain and liver were separated on a continuous Iodixanol gradient and analyzed for protein expression of tuberin, rabaptin-5, a TSC2

associated protein, EEA1, and endosomal protein, and TGN38, a trans-Golgi marker. The pattern of expression was similar between tuberin, rabaptin-5 and EEA1 but distinct from that of TGN38. Further, a substantial fraction of tuberin was found free in the cytosol and was re-distributed to the supernatant under conditions of high pH. These findings suggest that tuberin may shuttle between the cytosol and membranous organelles. Further, tuberin localization is not restricted to the Golgi but includes the endosomal compartment. This is consistent with a role of tuberin in vesicular transport.

3.70 Spatial organization of EGF receptor transmodulation by PDGF

Liu, P. and Anderson, R.G.W.
Biochem. Biophys. Res. Commun., ***261****, 695-700 (1999)*

Even though the modulation of EGF receptors by PDGF is well documented, it is not known where on the cell surface cross-talk between the two receptor systems takes place. The recent finding that both populations of receptors are concentrated in cell surface caveolae suggests that the confinement of the two' receptors to this space might facilitate their interaction. Here we show that stimulation of PDGF receptors in caveolae with PDGF causes a subpopulation of EGF receptors in the same membrane fraction to become phosphorylated on tyrosine. Coincident with tyrosine phosphorylation, the binding of EGF to its receptor markedly declines. Loss of EGF binding is partially blocked by tyrosine kinase inhibitors. Despite the close proximity of the two receptors in caveolae, we saw no evidence that EGF could stimulate PDGFR tyrosine phosphorylation. These results suggest that these two receptor systems are highly organized in caveolae.

3.71 Co-expression of scavenger receptor-BI and caveolin-1 is associated with enhanced selective cholesterol ester uptake in THP-1 macrophages

Matveev, S., van der Westhuyzen, D.R. and Smart, E.J**.**
J. Lipid Res., ***40****, 1647-1654 (1999)*

Scavenger receptor (SR)-BI mediates the selective uptake of high density lipoprotein (HDL) cholesteryl esters and the efflux of free cholesterol. In Chinese hamster ovary (CHO) cells, SR-BI is predominantly associated with caveolae which we have recently demonstrated are the initial loci for membrane transfer of HDL cholesteryl esters. Because cholesterol accumulation in macrophages is a critical event in atherogenesis, we investigated the expression of SR-BI and caveolin-1 in several macrophage cell lines. Human THP-1 monocytes were examined before and after differentiation to macrophages by treatment with 200 nM phorbol ester for 72 h. Undifferentiated THP-1 cells expressed caveolin-1 weakly whereas differentiation upregulated caveolin-1 expression greater than 50-fold. In contrast, both undifferentiated and differentiated THP-1 cells expressed similar levels of SR-BI. Differentiation of THP-1 cells increased the percent of membrane cholesterol associated with caveolae from 12% ± 1.9% to 38% ± 3.1%. The increase in caveolin-1 expression was associated with a 2- to 3-fold increase in selective cholesterol ether uptake from HDL. Two mouse macrophage cell lines, J774 and RAW, expressed levels of SR-BI similar to differentiated THP-1 cells but did not express detectable levels of caveolin-1. In comparison to differentiated THP-1 cells, RAW and J774 cells internalized 9- to 10-fold less cholesteryl ester. We conclude that differentiated THP-1 cells express both caveolin-1 and SR-BI and that their co-expression is associated with enhanced selective cholesteryl ester uptake.

3.72 The class B, type I scavenger receptor promotes the selective uptake of high density lipoprotein cholesterol ethers into caveolae

Graf, G.G., Connell, P.M., van der Westhuyzen, D.R. and Smart, E.J.
J. Biol. Chem., ***274(17)****, 12043-12048 (1999)*

The uptake of cholesterol esters from high density lipoproteins (HDLS) is characterized by the initial movement of cholesterol esters into a reversible plasma membrane pool. Cholesterol esters are subsequently internalized to a nonreversible pool. Unlike the uptake of cholesterol from low density lipoproteins, cholesterol ester uptake from HDL does not involve the internalization and degradation of the particle and is therefore termed selective. The class B, type I scavenger receptor (SR-BI) has been identified as an HDL receptor and shown to mediate selective cholesterol ester uptake. SR-BI is localized to cholesterol- and sphingomyelin- rich microdomains called caveolae. Caveolae are directly involved in cholesterol trafficking. Therefore, we tested the hypothesis that caveolae are acceptors for HDL-derived cholesterol ether (CE). Our studies demonstrate that in Chinese hamster ovary cells expressing SR-BI, >80% of the plasma membrane associated CE is present in caveolae after 7.5 min of selective cholesterol ether uptake. We also show that excess, unlabeled HDL can extract the radiolabeled CE from caveolae,

demonstrating that caveolae constitute a reversible plasma membrane pool of CE. Furthermore, 50% of the caveolae-associated CE can be chased into a nonreversible pool. We conclude that caveolae are acceptors for HDL-derived cholesterol ethers, and that caveolae constitute a reversible, plasma membrane pool of cholesterol ethers.

3.73 Polarized distribution of endogenous Racl and RhoA at the cell surface

Michaely, P.A., Mineo, C. Ying, Y-S. and Anderson, R.G.W.
*J. Biol. Chem., **274(30)**, 21430-21436 (1999)*

Racl and RhoA regulate membrane ruffling and stress fiber formation. Both molecules appear to exert their control from the plasma membrane. In fibroblasts stimulated with platelet-derived growth factor or lysophosphatidic acid, the reorganization of the cytoskeleton begins at specific sites on the cell surface. We now report that endogenous Racl and RhoA also have a polarized distribution at the cell surface. Cell fractionation and immunogold labeling show that in quiescent fibroblasts both of these molecules are concentrated in caveolae, which are plasma membrane domains that are associated with actin-rich regions of the cell. Treatment of these cells with platelet-derived growth factor stimulated the recruitment of additional Racl and RhoA to caveolae fractions, while lysophosphatidic acid only caused the recruitment of RhoA. We could reconstitute the recruitment of RhoA using either whole cell lysates or purified caveolae. Surprisingly, pretreatment of the lysates with exoenzyme C3 shifted both resident and recruited RhoA from caveolae to noncaveolae membranes. The shift in location was not caused by inactivation of the RhoA effector domain. Moreover, chimeric proteins containing the C-terminal consensus site for Racl and RhoA prenylation were constitutively targeted to caveolae fractions. These results suggest that the polarized distribution of Rho family proteins at the cell surface involves an initial targeting of the protein to caveolae and a mechanism for retaining it at this site.

3.74 Regulated migration of epidermal growth factor receptor from caveolae

Mineo, C., Gill, G.N. and Anderson, R.G.W.
*J. Biol. Chem., **274(43)**, 30636-30643 (1999)*

In quiescent fibroblasts, epidermal growth factor (EGF) receptors (EGFR) are initially concentrated in caveolae but rapidly move out of this membrane domain in response to EGF. To better understand the dynamic localization of EGFR to caveolae, we have studied the behavior of wild-type and mutant receptors expressed in cells lacking endogenous EGFR. All of the receptors we examined, including those missing the first 274 amino acids or most of the cytoplasmic tail, were constitutively concentrated in caveolae. By contrast, migration from caveolae required EGF binding, an active receptor kinase domain, and at least one of the five tyrosine residues present in the regulatory domain of the receptor. Movement appears to be modulated by Src kinase, is blocked by activators of protein kinase C, and occurs independently of internalization by clathrin coated pits. Two mutant receptors previously shown to induce an oncogenic phenotype lack the ability to move from caveolae in response to EGF, suggesting that a prolonged residence in this domain may contribute to abnormal cell behavior.

3.75 Oxidized low density lipoprotein displaces endothelial nitric-oxide synthase (eNOS) from plasmalemmal caveolae and impairs eNOS activation

Blair, A., Shaul, P.W., Yuhanna, I.S., Conrad, P.A. and Smart, E.J.
*J. Biol Chem., **274(45)**, 32512-32519 (1999)*

Hypercholesterolemia-induced vascular disease and atherosclerosis are characterized by a decrease in the bioavailability of endothelium-derived nitric oxide. Endothelial nitric-oxide synthase (eNOS) associates with caveolae and is directly regulated by the caveolar protein, caveolin. In the present study, we examined the effects of oxidized low density lipoprotein (oxLDL) on the subcellular location of eNOS, on eNOS activation, and on caveolar cholesterol in endothelial cells: We found that treatment with 10 μg/ml oxLDL for 60 min causes greater than 90% of eNOS and caveolin to leave caveolae. Treatment with oxLDL also inhibited acetylcholine-induced activation of eNOS but not prostacyclin production. oxLDL did not affect total cellular eNOS abundance. Oxidized LDL also did not affect the palmitoylation, myristoylation or phosphorylation of eNOS. Oxidized LDL, but not native LDL, or HDL depleted caveolae of cholesterol by serving as an acceptor for cholesterol. Cyclodextrin also depleted caveolae of cholesterol and caused eNOS and caveolin to translocate from caveolae. Furthermore, removal of oxLDL allowed eNOS and caveolin to return to caveolae. We conclude that oxLDL-induced depletion of caveolar cholesterol causes eNOS to leave caveolae and inhibits acetylcholine-induced activation of the enzyme. This process may be an important mechanism in the early pathogenesis of atherosclerosis.

3.76 Subcellular location of enzyme involved in oxidation on *n*-alkane by *Cladosporium resinae*
Goswami, P. and Cooney, J.J.
*Appl. Microbiol. Biotechnol., **51(6)**, 860-864 (1999)*

More than 70% of *n*-hexadecane-grown cells of *Cladosporium resinae* ATCC 22711 were converted to spheroplasts when they were treated with chinitase and lytic enzyme from *Trichoderma harziamum.* The light mitochondrial fraction, containing microbodies, mitochondria and vacuoles, was isolated from spheroplasts. Vacuoles in cells were demonstrated by the inability of acridine orange to stain organelles previously treated with 2.5 μM Bafilomycin A_1, a vacuolar ATPase inhibitor. Microbodies, mitochondria and vacuoles were separated from the light mitochondrial fraction by self-generated density gradient ultracentrifugation using **iodixanol** as gradient medium. NADH-dependent *n*-alkane monooxygenase activity and fatty alcohol oxidase activity were located in the cytoplasm and mitochondrial fractions respectively.

3.77 Persistent membrane association of activated and depalmitoylated G protein α subunits
Huang, C., Duncan, J.A., Gilman, A.G. and Mumby, S.M.
*Proc. Natl. Acad. Sci. USA, **96**, 412-417 (1999)*

Heterotrimeric signal-transducing G proteins are organized at the inner surface of the plasma membrane, where they are positioned to interact with membrane-spanning receptors and appropriate effectors. G proteins are activated when they bind GTP and inactivated when they hydrolyze the nucleotide to GDP. However, the topological fate of activated G protein α subunits is disputed. One model declares that depalmitoylation of α, which accompanies activation by a receptor, promotes release of the protein into the cytoplasm. Our data suggest that activation of G protein α subunits causes them to concentrate in subdomains of the plasma membrane but not to be released from the membrane. Furthermore, α subunits remained bound to the membrane when they were activated with guanosine5'-(3-*0*-thio)triphosphate and depalmitoylated with an acyl protein thioesterase. Limitation of α subunits to the plasma membrane obviously restricts their mobility and may contribute to the efficiency and specificity of signaling.

3.78 The yeast frataxin homologue mediates mitochondrial iron efflux
Radisky, D.C., Babcock, M.C. and Kaplan, J.
*J. Biol. Chem.,**274(8)**, 4497-4499 (1999)*

Mutations in the nuclear gene encoding the mitochondrial protein frataxin are responsible for the neurological disorder Friedreich ataxia (FA). Yeast strains with a deletion in the frataxin homologue *YFH1* accumulate excess iron in mitochondria and demonstrate mitochondrial damage. We show that in the absence of *YFH1*, mitochondrial damage is proportional to the concentration and duration of exposure to extracellular iron, establishing mitochondrial iron accumulation as causal to mitochondrial damage. Reintroduction of *YFH1* results in the rapid export of accumulated mitochondrial iron into the cytosol as free, non-heme bound iron, demonstrating that mitochondrial iron in the yeast FA model can be made bioavailable. These results demonstrate a mitochondrial iron cycle in which Yfhlp regulates mitochondrial iron efflux.

3.79 Induction of caveolae in the apical plasma membrane of Madin-Darby canine kidney cells
Verkade, P., Harder, T., Lafont, F. And Simons, K.
*J. Cell Biol., **148(4)**, 727-739 (1999)*

In this paper, we have analyzed the behavior of antibody cross-linked raft-associated proteins on the surface of MDCK cells. We observed that cross-linking of membrane proteins gave different results depending on whether cross-linking occurred on the apical or basolateral plasma membrane. Whereas antibody cross-linking induced the formation of large clusters on the basolateral membrane, resembling those observed on the surface of fibroblasts (Harder, T, P. Scheiffele, P. Verkade, and K. Simons. 1998. *J Cell Biol*. 929-942), only small (~100 nm) clusters formed on the apical plasma membrane. Cross-linked apical raft proteins e.g., GPI-anchored placental alkaline phosphatase (PLAP), influenza hemagglutinin, and gpl14 coclustered and were internalized slowly (~10% after 60 min). Endocytosis occurred through surface invaginations that corresponded in size to caveolae and were labeled with caveolin-1 antibodies. Upon cholesterol depletion the internalization of PLAP was completely inhibited. In contrast, when a non-raft protein, the mutant LDL receptor LDLR-CT22, was cross-linked, it was excluded from the clusters of raft proteins and was rapidly internalized via clathrin-coated pits. Since caveolae are normally present on

the basolateral membrane but lacking from the apical side, our data demonstrate that antibody cross-linking induced the formation of caveolae, which slowly internalized cross-linked clusters of raft-associated proteins.

3.80 Regulation of β-amyloid secretion by FE65, an amyloid protein precursor-binding protein
Sabo, S.L. et al
J. Biol. Chem., ***274(12)***, *7952-7957 (1999)*

The principal component of Alzheimer's amyloid plaques, Aβ, derives from proteolytic processing of the Alzheimer's amyloid protein precursor (APP). FE65 is a brain-enriched protein that binds to APP. Although several laboratories have characterized the APP-FE65 interaction in *vitro,* the possible relevance of this interaction to Alzheimer's disease has remained unclear. We demonstrate here that APP and FE65 co-localize in the endoplasmic reticulum/Golgi and possibly in endosomes. Moreover, FE65 increases translocation of APP to the cell surface, as well as both αAPP_s and Aβ secretion. The dramatic (4-fold) FE65-dependent increase in Aβ secretion suggests that agents which inhibit the interaction of FE65 with APP might reduce Aβ secretion in the brain and therefore be useful for preventing or slowing amyloid plaque formation.

3.81 The mixed lineage kinase DLK utilizes MKK7 and not MKK4 as substrate
Merritt, S.E. et al
J. Biol. Chem., ***274(15)***, *10195-10202 (1999)*

Mixed lineage kinases DLK (dual leucine zipper-bearing kinase) and MLK3 have been proposed to function as mitogen-activated protein kinase kinase kinases in pathways leading to stress-activated protein kinase/c-Jun NH_2-terminal kinase activation. Differences in primary protein structure place these MLK (mixed lineage kinase) enzymes in separate subfamilies and suggest that they perform distinct functional roles. Both DLK and MLK3 associated with, phosphorylated, and activated MKK7 in *vitro.* Unlike MLK3, however, DLK did not phosphorylate or activate recombinant MKK4 *in vitro.* In confirmatory experiments performed *in vivo,* DLK both associated with and activated MKK7. The relative localization of endogenous DLK, MLK3, MKK4, and MKK7 was determined in cells of the nervous system. Distinct from MLK3, which was identified in non-neuronal cells, DLK and MKK7 were detected predominantly in neurons in sections of adult rat cortex by immunocytochemistry. Subcellular fractionation experiments of cerebral cortex identified DLK and MKK7 in similar nuclear and extranuclear subcellular compartments. Concordant with biochemical experiments, however, MKK4 occupied compartments distinct from that of DLK and MKK7. That DLK and MKK7 occupied subcellular compartments distinct from MKK4 was confirmed by immunocytochemistry in primary neuronal culture. The dissimilar cellular specificity of DLK and MLK3 and the specific substrate utilization and subcellular compartmentation of DLK suggest that specific mixed lineage kinases participate in unique signal transduction events.

3.82 Mgm101p is a novel component of the mitochondrial nucleoid that binds DNA and is required for the repair of oxidatively damaged mitochondrial DNA
Meeusen, S. et al
J. Cell Biol., ***145(2)***, *291-304 (1999)*

Maintenance of mitochondrial DNA (mtDNA) during cell division is required for progeny to be respiratory competent. Maintenance involves the replication, repair, assembly, segregation, and partitioning of the mitochondrial nucleoid. *MGM101* has been identified as a gene essential for mtDNA maintenance in *S. cerevisiae,* but its role is unknown. Using liquid chromatography coupled with tandem mass spectrometry, we identified Mgm101p as a component of highly enriched nucleoids, suggesting that it plays a nucleoid specific role in maintenance. Subcellular fractionation, indirect immunofluorescence and GFP tagging show that Mgm101p is exclusively associated with the mitochondrial nucleoid structure in cells. Furthermore, DNA affinity chromatography of nucleoid extracts indicates that Mgm101p binds to DNA, suggesting that its nucleoid localization is in part due to this activity. Phenotypic analysis of cells containing a temperature sensi*tive mgm101* allele suggests that Mgml0lp is not involved in mtDNA packaging, segregation, partitioning or required for ongoing mtDNA replication. We examined Mgml0lp's role in mtDNA repair. As compared with wild-type cells, *mgm101* cells were more sensitive to mtDNA damage induced by UV irradiation and were hypersensitive to mtDNA damage induced by gamma rays and H_2O_2 treatment. Thus, we propose that Mgm101p performs an essential function in the repair of oxidatively damaged mtDNA that is required for the maintenance of the mitochondrial genome.

3.83 Association of sterol- and glycosylphosphatidylinositol-linked proteins with *Drosophilia* raft lipid microdomains

Rietveld, A., Neutz, S., Simons, K. and Eaton, S.
J. Biol. Chem., ***274(17)***, *12049-12054 (1999)*

In vertebrates, the formation of raft lipid microdomains plays an important part in both polarized protein sorting and signal transduction. To establish a system in which raft-dependent processes could be studied genetically, we have analyzed the protein and lipid composition of these microdomains in *Drosophila melanogaster*. Using mass spectrometry, we identified the phospholipids, sphingolipids, and sterols present in *Drosophila* membranes. Despite chemical differences between *Drosophila* and mammalian lipids, their structure suggests that the biophysical properties that allow raft formation have been preserved. Consistent with this, we have identified a detergent-insoluble fraction of *Drosophila* membranes that, like mammalian rafts, is rich in sterol, sphingolipids, and glycosylphosphatidylinositol-linked proteins. We show that the sterol-linked Hedgehog N-terminal fragment associates specifically with this detergent-insoluble membrane fraction. Our findings demonstrate that raft formation is preserved across widely separated phyla in organisms with different lipid structures. They further suggest sterol modification as a novel mechanism for targeting proteins to raft membranes and raise the possibility that signaling and polarized intracellular transport of Hedgehog are based on raft association.

3.84 N-glycans mediate the apical sorting of a GPI-anchored, raft-associated protein in Madin-Darby canine kidney cells

Benting, J.H., Rietveld, A.G. and Simons, K.
J. Cell Biol., ***146(2)***, *313-320 (1999)*

Glycosyl-phosphatidylinositol (GPI)-anchored proteins are preferentially transported to the apical cell surface of polarized Madin-Darby canine kidney (MDCK) cells. It has been assumed that the GPI anchor itself acts as an apical determinant by its interaction with sphingolipid-cholesterol rafts. We modified the rat growth hormone (rGH), an unglycosylated, unpolarized secreted protein, into a GPI-anchored protein and analyzed its surface delivery in polarized MDCK cells. The addition of a GPI anchor to rGH did not lead to an increase in apical delivery of the protein. However, addition of N-glycans to GPI-anchored rGH resulted in predominant apical delivery, suggesting that N-glycans act as apical sorting signals on GPI-anchored proteins as they do on transmembrane and secretary proteins, In contrast to the GPI-anchored rGH, a transmembrane form of rGH which was not raft-associated accumulated intracellularly. Addition of N-glycans to this chimeric protein prevented intracellular accumulation and led to apical delivery.

3.85 Identification and characterization of polycystin-2, the *PKD2* gene product

Cai, Y. et al
J. Biol. Chem., ***274(40)***, *28557-28565 (1999)*

PKD2, the second gene for the autosomal dominant polycystic kidney disease (ADPKD), encodes a protein, polycystin-2, with predicted structural similarity to cation channel subunits. However, the function of polycystin-2 remains unknown. We used polyclonal antisera specific for the intracellular NH_2 and COOH termini to identify polycystin-2 as an ~110-kDa integral membrane glycoprotein. Polycystin-2 from both native tissues and cells in culture is sensitive to Endo H suggesting the continued presence of high-mannose oligosaccharides typical of pre-middle Golgi proteins. Immunofluorescent cell staining of polycystin-2 shows a pattern consistent with localization in the endoplasmic reticulum. This finding is confirmed by co-localization with protein-disulfide isomerase as determined by double indirect immunofluorescence and co-distribution with calnexin in subcellular fractionation studies. Polycystin-2 translation products truncated at or after Gly^{821} retain their exclusive endoplasmic reticulum localization while products truncated at or before Glu^{787} additionally traffic to the plasma membrane. Truncation mutants that traffic to the plasma membrane acquire Endo H resistance and can be biotinylated on the cell surface in intact cells. The 34-amino acid region GLU^{787}-Ser^{820}, containing two putative phosphorylation sites, is responsible for the exclusive endoplasmic reticulum localization of polycystin-2 and is the site of specific interaction with an as yet unidentified protein binding partner for polycystin-2. The localization of full-length polycystin-2 to intracellular membranes raises the possibility that the PKD2 gene product is a subunit of intracellular channel complexes.

3.86 NK lytic-associated molecule: A novel gene selectively expressed in cells with cytolytic function
Kozlowski, M., Schorey, J., Portis, T., Grigoriev, V. and Kornbluth, J.
*J. Immunol., **163**, 1775-1785 (1999)*

NK cells are most effective in killing a broad spectrum of primary tumor cells after stimulation with cytokines. We have cloned a novel gene, designated NKLAM (for NK lytic-associated molecule), whose expression is associated with this cytokine-enhanced process. NKLAM expression is up-regulated in NK cells by IL-2 and IFNβ. NKLAM is also selectively expressed by activated macrophages and CTL. Treatment of NK cells and CTL with NKLAM antisense oligonucleotides specifically decreases their cytolytic activity, while having no effect on cell growth. The NKLAM gene encodes a 62-kDa ring finger-containing protein that localizes to the cytoplasmic granules in NK cells. Further study of this gene may add to our understanding of cytotoxic processes common to NK cells, CTL, and activated macrophages.

3.87 Glycoprotein reglucosylation and nucleotide sugar utilization in the secretory pathway: identification of a nucleoside diphosphatase in the endoplasmic reticulum
Trombetta, E.S. and Helenius, A.
*The EMBO J., **18(12)**, 3282-3292 (1999)*

UDP is generated in the lumen of the endoplasmic reticulum (ER) as a product of the UDP-glucose-dependent glycoprotein reglucosylation in the calnexin/calreticulin cycle. We describe here the identification, purification and characterization of an ER enzyme that hydrolyzes UDP to UMP. This nucleoside diphosphatase is a ubiquitously expressed, soluble 45 kDa glycoprotein devoid of transmembrane domains and KDEL-related ER localization sequences. It requires divalent cations for activity and hydrolyzes UDP, GDP and IDP but not any other nucleoside di-, mono- or triphosphates, nor thiamine pyrophosphate. By eliminating UDP, which is an inhibitory product of the UDP-Glc:glycoprotein glucosyltransferase, it is likely to promote reglucosylation reactions involved in glycoprotein folding and quality control in the ER.

3.88 Characterization of the internalization pathways for the cystic fibrosis transmembrane conductance regulator
Bradbury, N.A. et al
*Am. J. Physiol., **276** (Lung Cell. Mol. Physiol., 20), L659-L668 (1999)*

Mutations in the gene encoding the cystic fibrosis (CF) transmembrane conductance regulator (CFTR) chloride channel give rise to the most common lethal genetic disease of Caucasian populations, CF. Although the function of CFTR is primarily related to the regulation of apical membrane chloride permeability, biochemical, immunocytochemical, and functional studies indicate that CFTR is also present in endosomal and *trans* Golgi compartments. The molecular pathways by which CFTR is internalized into intracellular compartments are not fully understood. To define the pathways for CFTR internalization, we investigated the association of CFTR with two specialized domains of the plasma membrane, clathrin-coated pits and caveolae. Internalization of CFTR was monitored after cell surface biotinylation and quantitation of cell surface CFTR levels after elution of cell lysates from a monomeric avidin column. Cell surface levels of CFTR were determined after disruption of caveolae or clathrin-coated vesicle formation. Biochemical assays revealed that disrupting the formation of clathrin-coated vesicles inhibited the internalization of CFTR from the plasma membrane, resulting in a threefold increase in the steady-state levels of cell surface CFTR. In contrast, the levels of cell surface CFTR after disruption of caveolae were not different from those in control cells. In addition, although our studies show the presence of caveolin at the apical membrane domain of human airway epithelial cells, we were unable to detect CFTR in purified caveolae. These results suggest that CFTR is constitutively internalized from the apical plasma membrane via clathrin-coated pits and that CFTR is excluded from caveolae.

3.89 Cloning, expression, and cellular localization of a human prenylcysteine lyase
Tschantz, W.R., Zhang, L. and Casey, P.J
*J. Biol. Chem., **274(50)**, 35802-35808 (1999)*

Prenylated proteins contain either a 15-carbon farnesyl or 20-carbon geranylgeranyl isoprenoid covalently attached to cysteine residues at or near their C terminus. These proteins constitute up to 2% of total cellular protein in eukaryotic cells. The degradation of prenylated proteins raises a metabolic challenge to the cell, because the thioether bond of the modified cysteine is quite stable. We recently identified and isolated an enzyme termed prenylcysteine lyase that cleaves the prenylcysteine to free cysteine and an

isoprenoid product (Zhang, L., Tschantz, W. IL, and Casey, P. J. (1997) *J. Biol Chem.* 272,23354-23359). To facilitate the molecular characterization of this enzyme, its cloning was undertaken. Overlapping cDNA clones encoding the complete coding sequence of this enzyme were obtained from a human cDNA library. The open reading frame of the gene encoding prenylcysteine lyase is 1515 base pairs and has a nearly ubiquitous expression pattern with a message size of 6 kilobase pairs. Recombinant prenylcysteine lyase was produced in a baculovirus-Sf9 expression system. Analysis of both the recombinant and native enzyme revealed that the enzyme is glycosylated and contains a signal peptide that is cleaved during processing. Additionally, the subcellular localization of this enzyme was determined to be lysosomal. These findings strengthen the notion that prenylcysteine lyase plays an important role in the final step in the degradation of prenylated proteins and will allow further physiological and biochemical characterization of this enzyme.

3.90 The amyloid precursor protein interacts with G_o heterotrimeric protein within a cell compartment specialized in signal transduction

Brouillett, E. et al
J. Neurosci., ***19(5)***, *1717-1727 (1999)*

The function of the β-amyloid protein precursor (βAPP), a transmembrane molecule involved in Alzheimer pathologies, is poorly understood. We recently reported the presence of a fraction of βAPP in cholesterol and sphingoglycolipid-enriched microdomains (CSEM), a caveolae-like compartment specialized in signal transduction. To investigate whether βAPP actually interferes with cell signaling, we reexamined the interaction between βAPP and G_o GTPase. In strong contrast with results obtained with reconstituted phospholipid vesicles (Okamoto et al., 1995), we find that incubating total neuronal membranes with 22Cl1, an antibody that recognizes an N-terminal βAPP epitope, reduces high-affinity G_o GTPase activity. This inhibition is specific of $G_{\alpha o}$ and is reproduced, in the absence of 22Cl1, by the addition of the βAPP C-terminal domain but not by two distinct mutated βAPP C-terminal domains that do not bind $G_{\alpha o}$. This inhibition of $G_{\alpha o}$ GTPase activity by either 22Cl1 or wild-type βAPP cytoplasmic domain suggests that intracellular interactions between βAPP and $G_{\alpha o}$ could be regulated by extracellular signals. To verify whether this interaction is preserved in CSEM, we first used biochemical, immunocytochemical, and ultrastructural techniques to unambiguously confirm the colocalization of $G_{\alpha o}$ and βAPP in CSEM. We show that inhibition of basal $G_{\alpha o}$ GTPase activity also occurs within CSEM and correlates with the coimmunoprecipitation of $G_{\alpha o}$ and βAPP. The regulation of $G_{\alpha o}$ GTPase activity by βAPP in a compartment specialized in signaling may have important consequences for our understanding of the physiopathological functions of βAPP.

3.91 ER/Golgi intermediates acquire Golgi enzymes by Bredelfin A – sensitive retrograde transport in vitro

Lin, C-C., Love, H.D., Gushue, J.N., Bergeron, J.J.M. and Osterman, J.
J. Cell. Biol., ***147(7)***, *1457-1472 (1999)*

Secretary proteins exit the ER in transport vesicles that fuse to form vesicular tubular clusters (VTCs) which move along microtubule tracks to the Golgi apparatus. Using the well-characterized in vitro approach to study the properties of Golgi membranes, we determined whether the Golgi enzyme NAGT I is transported to ER/Golgi intermediates. Secretary cargo was arrested at distinct steps of the secretary pathway of a glycosylation mutant cell line, and in vitro complementation of the glycosylation defect was determined. Complementation yield increased after ER exit of secretary cargo and was optimal when transport was blocked at an ER/Golgi intermediate step. The rapid drop of the complementation yield as secretary cargo progresses into the stack suggests that Golgi enzymes are preferentially targeted to ER/Golgi intermediates and not to membranes of the Golgi stack. Two mechanisms for in vitro complementation could be distinguished due to their different sensitivities to brefeldin A (BFA). Transport occurred either by direct fusion of preexisting transport intermediates with ER/Golgi intermediates, or it occurred as a BFA-sensitive and most likely COP I-mediated step. Direct fusion of ER/Golgi intermediates with cisternal membranes of the Golgi stack was not observed under these conditions.

3.92 Membrane raft microdomains mediate front-rear polarity in migrating cells
Manes, S. et al
*EMBO J., **18(22)**, 6211-6220 (1999)*

The acquisition of spatial and functional asymmetry between the rear and the front of the cell is a necessary step for cell chemotaxis. Insulin-like growth factor-1 (IGF-I) stimulation of the human adenocarcinoma MCF-7 induces a polarized phenotype characterized by asymmetrical CCR5 chemokine receptor redistri-bution to the leading cell edge. CCR5 associates with membrane raft microdomains, and its polarization parallels redistribution of raft molecules, including the raft-associated ganglioside GM1, glycosylphosphat-idylinositol- anchored green fluorescent protein and ephrinBl, to the leading edge. The non-raft proteins transferrin receptor and a mutant ephrinB1 are distributed homogeneously in migrating MCF-7 cells, supporting the raft localization requirement for polarization. IGF-I stimulation of cholesterol-depleted cells induces projection of multiple pseudopodia over the entire cell periphery, indicating that raft disruption specifically affects the acquisition of cell polarity but not IGF-I-induced protrusion activity. Cholesterol depletion inhibits MCF-7 chemotaxis, which is restored by replenishing cholesterol. Our results indicate that initial segregation between raft and non-raft membrane proteins mediates the necessary, redistribution of specialized molecules for cell migration.

3.93 Isolated rabbit enterocytes as a model cell system for investigations of chylomicron assembly and secretion
Cartwright, I.J. and Higgins, J.A.
*J. Lipid Res., **40**, 1357-1365 (1999)*

A method is described for the isolation of viable enterocytes from rabbit small intestine. The procedure can also be used to isolate populations of epithelial cells from the crypt/villus gradient. The isolated enterocytes synthesized and secreted apoB-48 and triacylglycerol in particles of the density of chylomicrons. Secretion was stimulated by addition of bile salt/lipid micelles. Pulse-chase experiments demonstrated that newly synthesized apoB-48 is degraded intracellularly and that degradation is inhibited by provision of lipid micelles, suggesting that regulation of chylomicron assembly and secretion is broadly similar to that of very low density lipoprotein assembly in hepatocytes. This procedure for preparation of isolated enterocytes will provide a useful model system for investigation of the molecular details of chylomicron assembly.

3.94 Caveolin-3 upregulation activates β-secretase-mediated cleavage of the amyloid precursor protein in Alzheimer's disease
Nisshiyama, K. et al
*J. Neurosci., **19(15)**, 6538-6548 (1999)*

Here, we investigate the involvement of caveolins in the pathophysiology of Alzheimer's disease (AD). We show dramatic upregulation of caveolin-3 immunoreactivity in astroglial cells surrounding senile plaques in brain tissue sections from authentic AD patients and an established transgenic mouse model of AD. In addition, we find that caveolin-3 physically interacts and biochemically colocalizes with amyloid precursor protein (APP) both *in vivo and in vitro*. Interestingly, recombinant overexpression of caveolin-3 in cultured cells stimulated β-secretase-mediated processing of APP. Immunoreactivities of APP and presenilins were concomitantly increased in caveolin-3-positive astrocytes. Because the presenilins also form a physical complex with caveolin-3, caveolin-3 may provide a common platform for APP and the presenilins to associate in astrocytes. In AD, augmented expression of caveolin-3 and presenilins in reactive astrocytes may alter APP processing, leading to the overproduction of its toxic amyloid metabolites.

3.95 Immunoisolation of caveolae with high affinity antibody binding to the oligomeric caveolin cage
Oh, P. and Schnitzer, J.E.
*J. Biol. Chem, **274 (33)**, 23144-23154 (1999)*

Defining the molecular composition of caveolae is essential in establishing their molecular architecture and functions. Here, we identify a high affinity monoclonal antibody that is specific for caveolin-h and rapidly binds caveolin oligomerized around intact caveolae. We use this antibody (i) to develop a new simplified method for rapidly isolating caveolae from cell and tissue homogenates without using the silica-coating technology and (ii) to analyze various caveolae isolation techniques to understand how they work and why they yield different compositions. Caveolae are immunoisolated from rat lung plasma membrane fractions

subjected to mechanical disruption. Sonication of plasma membranes, isolated with or without silica coating, releases caveolae along with other similarly buoyant microdomains and, therefore, requires immunoisolation to purify caveolae. Shearing of silica-coated plasma membranes provides a homogeneous population of caveolae whose constituents (i) remain unchanged after immunoisolation, (ii) all fractionate bound to the immunobeads, and (iii) appear equivalent to caveolae immunoisolated after sonication. The caveolae immunoisolated from different low density fractions are quite similar in molecular composition. They contain a subset of key signaling molecules *(i.e.* G protein and endothelial nitric oxide synthase) and are markedly depleted in glycosylphosphatidylinositol-anchored proteins, β-actin, and angiotensin-converting enzyme. All caveolae isolated from the cell surface of lung microvascular endothelium *in vivo* appear to be coated with caveolin-lα. Caveolin-1β and -2 can also exist in these same caveolae. The isolation and analytical procedures as well as the time-dependent dissociation of signaling molecules from caveolae contribute to key compositional differences reported in the literature for caveolae. This new, rapid, magnetic immunoisolation procedure provides a consistent preparation for use in the molecular analysis of caveolae.

3.96 The growth-related, translationally controlled protein P23 has properties of a tubulin protein and associates transiently with microtubules during the cell cycle
Gachet, Y. et al
J. Cell Sci., ***112***, *1257-1271 (1999)*

The translationally controlled protein P23 was discovered by the early induction of its rate of synthesis after mitogenic stimulation of mouse fibroblasts. P23 is expressed in almost all mammalian tissues and it is highly conserved between animals, plants and yeast. Based on its amino acid sequence. P23 cannot be attributed to any known protein family, and its cellular function remains to be elucidated. Here, we present evidence that P23 has properties of a tubulin binding protein that associates with microtubules in a cell cycle-dependent manner. (1) P23 is a cytoplasmic protein that occurs in complexes of 100-150 kDa, and part of P23 can be immunoprecipitated from HeLa cell extracts with anti-tubulin antibodies. (2) In Immunolocalization experiments we find P23 associated with microtubules during G_1, S, G_2 and early M phase of the cell cycle. At metaphase, P23 is also bound to the mitotic spindle, and it is detached from the spindle during metaphase-anaphase transition. (3) A GST-P23 fusion protein interacts with α- and β-tubulin, and recombinant P23 binds to taxol-stabilised microtubules in vitro. The tubulin binding domain of P23 was identified by mutational analysis; it shows similarity to part of the tubulin binding domain of the microtubule-associated protein MAP-1B. (4) Overexpression of P23 results in cell growth retardation and its alterations of cell morphology. Moreover, elevation of P23 levels leads to microtubule rearrangements and to an increase in microtubule mass and stability.

3.97 VIP36 localisation to the early secretory pathway
Fullekrug, J., Scheiffele, P. and Simons, K.
J. Cell Sci., ***112***, *2813-2821 (1999)*

VIP36, an integral membrane protein previously isolated from epithelial MDCK cells, is an intracellular lectin of the secretory pathway. Overexpressed VIP36 had been localized to the Golgi complex, plasma membrane and endocytic structures suggesting post-Golgi trafficking of this molecule (Fiedler et al, 1994). Here we provide evidence that endogenous VIP36 is localized to the Golgi apparatus and the early secretory pathway of MDCK and Vero cells and propose that retention is easily saturated. High resolution confocal microscopy, shows partial overlap of VIP36 with Golgi marker proteins. Punctate cytoplasmic structures colocalize with coatomer and ERGIC-53, labeling ER-Golgi intermediate membrane structures. Cycling of VIP36 is suggested by colocalization with anterograde cargo trapped in pre-Golgi structures and modification of its N-linked carbohydrate by glycosylation enzymes of medial Golgi cisternae. Furthermore, after brefeldin A treatment VIP36 is segregated from resident Golgi proteins and codistributes with ER-Golgi recycling proteins.

3.98 Acyl and alkyl chain length of GPI-anchors is critical for raft association in vitro
Benting, J., Rietveld, A., Ansorge, I. and Simons, K
FEBS Lett., ***462***, *47-50 (1999)*

We determined the acyl and alkyl chain composition of GPI-anchors isolated from MDCK and Fischer rat thyroid (FRT) cells. Both cell lines synthesize GPI-anchors containing C16/C18 or C18/C18 saturated acyl and alkyl chains. The GPI-anchored placental alkaline phosphatase (PLAP) expressed in both cells is raft-associated and PLAP purified from FRT cells is raft-associated in vitro when reconstituted into liposomes

containing raft lipids. In contrast, the GPI-anchored variant surface glycoprotein from *Trypanosoma brucei*, which contains C14 acyl and alkyl chains, shows no significant raft association after reconstitution in vitro. These data indicate that the acyl and alkyl chain composition of GPI-anchors determines raft association.

3.99 EphrinB ligands recruit GRIP family PDZ adaptor proteins into raft membrane microdomains
Bruckner, K. et al
*Neuron, **22**, 511-524 (1999)*

Transmembrane ephrinB proteins have important functions during embryonic patterning as ligands for Eph receptor tyrosine kinases and presumably as signal-transducing receptor-like molecules. Consistent with "reverse" signaling, ephrinB1 is localized in sphingo-lipid/cholesterol-enriched raft microdomains, platforms for the localized concentration and activation of signaling molecules. Glutamate receptor-interacting protein (GRIP) and a highly related protein, which we have termed GRIP2, are recruited into these rafts through association with the C-terminal PDZ target site of ephrinB1. Stimulation of ephrinB1 with soluble EphB2 receptor ectodomain causes the formation of large raft patches that also contain GRIP proteins. Moreover, a GRIP-associated serine/threonine kinase activity is recruited into ephrinB1-GRIP complexes. Our findings suggest that GRIP proteins provide a scaffold for the assembly of a multiprotein signaling complex downstream of ephrinB ligands.

3.100 In vivo imaging of tumors with protease-activated near-infrared fluorescent probes
Weissleder, R., Tung, C-H., Mahmood, U. and Bogdanov, A.
*Nature Biotech., **17**, 375-378 (1999)*

We have developed a method to image tumor-associated lysosomal protease activity in a xenograft mouse model In vivo using autoquenched near-infrared fluorescence (NIRF) probes. NIRF probes were bound to a long circulating graft copolymer consisting of poly-L-lysine and methoxypolyethylene glycol succinate. Following intravenous Injection, the NIRF probe carrier accumulated in solid tumors due to its long circulation time and leakage through tumor neovasculature. Intratumoral NIRF signal was generated by lysosomal proteases in tumor cells that cleave the macromolecule, thereby releasing previously quenched fluorochrome. In vivo imaging showed a 12-fold increase in NIRF signal, allowing the detection of tumors with submillimeter-sized diameters. This strategy can be used to detect such early stage tumors in vivo and to probe for specific enzyme activity.

3.101 Two transmembrane aspartates in presenilin-1 required for presenilin endoproteolysis and γ-secretase activity
Wolfe, M.S., Xia, W., Ostraszewski, B.L., Diehl, T.S., Kimberly, W.T and Selkoe, D.J.
*Nature **398**, 513-517 (1999)*

Accumulation of the amyloid-β protein (Aβ) in the cerebral cortex is an early and invariant event in the pathogenesis of Alzheimer's disease. The final step in the generation of Aβ from the β-amyloid precursor protein is an apparently intramembranous proteolysis by the elusive γ-secretase(s). The most common cause of familial Alzheimer's disease is mutation of the genes encoding presenilins 1 and 2, which alters γ-secretase activity to increase the production of the highly amyloidogenic $A\beta_{42}$ isoform. Moreover, deletion of presenilin-1 in mice greatly reduces γ-secretase activity, indicating that presenilin-1 mediates most of this proteolytic event. Here we report that mutation of either of two conserved transmembrane (TM) aspartate residues in presenilin-1, Asp 257 (in TM6) and Asp 385 (in TM7), substantially reduces Aβ production and increases the amounts of the carboxy-terminal fragments of β-amyloid precursor protein that are the substrates of γ-secretase. We observed these effects in three different cell lines as well as in cell-free microsomes. Either of the Asp→ Ala mutations also prevented the normal endoproteolysis of presenilin-1 in the TM6→TM7 cytoplasmic loop. In a functional presenilin-1 variant (carrying a deletion in exon 9) that is associated with familial Alzheimer's disease and which does not require this cleavage, the Asp 385→Ala mutation still inhibited γ-secretase activity. Our results indicate that the two transmembrane aspartate residues are critical for both presenilin-I endoproteolysis and γ-secretase activity, and suggest that presenilin 1 is either a unique diaspartyl cofactor for γ-secretase or is itself γ-secretase, an autoactivated intramembranous aspartyl protease.

3.102 Evaluation of the affinity and turnover number of both hepatic mitochondrial and microsomal carnitine acyltransferases: relevance to intracellular partitioning of Acyl-CoAs
Abo-Hashema, K.A., Cake, M.H., Lukas, M.A. and Knudsen, J.
*Biochemistry, **38**, 15840-15847 (1999)*

Mitochondrial carnitine palmitoyltransferase I (CPT I) and microsomal carnitine acyltransferase I (CAT I) regulate the entry of fatty acyl moieties into their respective organelles. Thus, CPT I and CAT I occupy prominent positions in the pathways responsible for energy generation in mitochondria and the assembly of VLDL in the endoplasmic reticulum, respectively. Previous attempts to determine the intrinsic kinetic properties of CPT I and CAT I have been hampered by the occurrence of sigmoidal velocity curves. This was overcome, in this study, by the inclusion of recombinant acyl-CoA binding protein in the assay medium. For the first time, we have determined the concentrations of total functional enzyme (E(t)) by specific radiolabeling of the active site, the dissociation constants (K(d)) and the turnover numbers of CPT I and CAT I toward the CoA esters of oleic acid (C18:1) and docosahexaenoic acid (C22:6). The data show that carnitine inhibits CAT I at physiological concentrations which are not inhibitory to CPT I. Thus, carnitine concentration is likely to be a significant factor in determining the partitioning of acyl-CoAs between mitochondria and microsomes, a role which has not been previously recognized. Moreover, the finding that CAT I elicits a lower turnover toward the CoA ester of C22:6 (25 s(-)(1)) than toward that of C18:1 (111 s(-)(1)), while having similar K(d) values, suggests the use of this polyunsaturated fatty acid to inhibit VLDL biosynthesis.

3.103 The protective role of high-density lipoproteins in atherosclerosis
Mingpeng, S. and Zongli, W.
*Exp. Gerontol., **34**, 539-548 (1999)*

Serum high-density lipoprotein level is known to be correlated inversely with the incidence and mortality rates of ischemic heart disease. Although some reports pointed out that in case of hyperalphalipoproteinemia, lesions in the coronary arteries were occasionally found, it is also noticed that in very rare condition, no atheromatous lesions found even in patients with hereditary alphalipoprotein deficiency (Funke et al., 1991). However, clinical surveys have confirmed that high high-density-lipoprotein cholesterol level is favorable in preventing the development of atheroclerotic lesion and high-density lipoprotein together with apolipoprotein AI are currently considered to be the most reliable parameters in predicting the development of atherosclerosis in hyperlipidemia.

3.104 Membrane structure of caveolae and isolated caveolin-rich vesicles
Westermann, M., Leutbecher, H. and Meyer, H.W.
*Histochem. Cell Biol., **111**, 71-81 (1999)*

Caveolae are specialized invaginated domains of the plasma membrane. Using freeze-fracture electron microscopy, the shape of caveolae and the distribution of intramembrane particles (integral membrane proteins) were analyzed. The caveolar membrane is highly curved and forms flask-like invaginations with a diameter of 80-120 nm with an open porus of 30-50 nm in diameter. The fracture faces of caveolar membranes are nearly free of intramembrane particles. Protein particles in a circular arrangement surrounding the caveolar opening were found on plasma membrane fracture faces. For isolation of caveolin-enriched membrane vesicles, the method of Triton X-100 solubilization, as well as a detergent-free isolation method, was used. The caveolin-rich vesicles had an average size of between 100 and 200 nm. No striated coat could be detected on the surface of isolated caveolin-rich vesicles. Areas of clustered intramembrane particles were found frequently on membrane fracture faces of caveolin-rich vesicles. The shape of these membrane protein clusters is often ring-like with a diameter of 30-50 nm. Membrane openings were found to be present in the caveolin-rich membrane vesicles, mostly localized in the areas of the clustered membrane proteins. Immunogold labeling of caveolin showed that the protein is a component within the membrane protein clusters and is not randomly distributed on the membrane of caveolin-rich vesicles.

3.105 Caveolin interacts with Trk A and p75^{NTR} and regulates neurotrophin signaling pathways
Bilderback, T.R., Gazula, V-R., Lisanti, M.P. and Dobrowsky, R.T.
*J. Biol. Chem., **274(1)**, 257-263 (1999)*

Neurotrophins signal through Trk tyrosine kinase receptors and the low-affinity neurotrophin receptor p75^{NTR}. We have shown previously that activation of Trk A tyrosine kinase activity can inhibit p75^{NTR}-dependent sphingomyelin hydrolysis, that caveolae are a localized site for p75^{NTR} signaling, and that caveolin can directly interact with p75^{NTR}. The ability of caveolin to also interact with tyrosine kinase receptors and inhibit their activity led us to hypothesize that caveolin expression may modulate interactions between neurotrophin signaling pathways. PC12 cells were transfected with caveolin that was expressed efficiently and targeted to the appropriate membrane domains. Upon exposure to nerve growth factor (NGF), caveolin-PC12 cells were unable to develop extensive neuritic processes. Caveolin expression in PC12 cells was found to diminish the magnitude and duration of Trk A activation *in vivo*. This inhibition may be due to a direct interaction of caveolin with Trk A, because Trk A co-immunoprecipitated with caveolin from Cav-Trk A-PC12 cells, and a glutathione *S*-transferase-caveolin fusion protein bound to Trk A and inhibited NGF-induced autophosphorylation *in vitro*. Furthermore, the *in vivo* kinetics of the inhibition of Trk A tyrosine kinase activity by caveolin expression correlated with an increased ability of NGF to induce sphingomyelin hydrolysis through p75^{NTR}. In summary, our results suggest that the interaction of caveolin with neurotrophin receptors may have functional consequences in regulating signaling through p75^{NTR} and Trk A in neuronal and glial cell populations.

3.106 Presence of cholyl- and chenodexoycholyl- coenzyme A thioesterase activity in human liver
Solaas, K., Sletta, R.J., Sρreide, O. and Kase, B.F.
*Scand. J. Clin. Lab. Invest., **60**, 91-102 (2000)*

In human liver homogenate the formation of bile acid..CoA thioesters is localized both to the microsomal fraction catalysed by an ATP-dependent synthetase and to the peroxisomal fraction catalysed by the thiolase in the last step of the β-oxidative cleavage of the 5β-cholestanoyl side chain. The cytosolic bile acid-CoA:amino acid N-acyltransferase catalyse the conjugation of the CoA-activated bile acids with taurine or glycine prior to secretion into bile. The formation of bile acid-CoA esters is considered the rate-limiting step in bile acid amidation. So far, a bile acid-CoA cleaving activity has not been assessed in the research of bile acid aniidation in human liver. In this work, a bile acid-CoA cleaving activity has been demonstrated at a rate that may influence the concentration of bile acid-CoA thioesters, free bile acids and amidated bile acids within the hepatocyte. Recently, it was shown that free chenodeoxycholic acid, formed by the thioesterase, is the physiological ligand of the farnesoid X receptor.

A multiorganelle distribution of the bile acid-CoA hydrolytic activity was found. In the postnuclear fraction of human liver homogenate, apparent K_m and V_{max} for the cleavage of choloyl-CoA were 7.7 x 10^{-5} mol/L and 3.6 nmol x mg^{-1} x min^{-1}, respectively. The corresponding values for chenodeoxycholoyl-CoA cleavage were 7.1 x 10^{-5} mol/L and 4.8 nmol x mg^{-1} x min^{-1}. Hydrolytic activities were detected in the microsomal and the peroxisomal fractions where the bile acid-CoA esters are formed as well as in cytosol housing the N-acyltransferase activity. Compared to the bile acid-CoA synthetase activities, the hydrolytic activities were considerably higher, both in the postnuclear fraction and in the microsomal fraction. The thioesterase activities were in the same range as detected for the N-acyltransferase activities both in the postnuclear fraction and in the cytosolic fraction. The mere presence of thioesterase in microsomes, peroxisomes and cytosol seems counterproductive to bile acid amidation. The thioesterases may have an indirect regulatory function on the bile acid synthesis and are important for the regulation of bile acid synthesis by providing free chenodeoxycholic acid, the most potent activator of the farnesoid X receptor.

3.107 Characterization of insulin-responsive GLUT4 storage vesicles isolated from 3T3-L1 adipocytes
Hashiramoto, M. and James, D.E.
*Mol. Cell Biol., **20(1)**, 416-427 (2000)*

Insulin regulates glucose transport in muscle and adipose tissue by triggering translocation of a facilitative glucose transporter, GLUT4, from an intracellular compartment to the cell surface. It has previously been suggested that GLUT4 is segregated between endosomes, the trans-Golgi network (TGN), and a postendosomal storage compartment. The aim of the present study was to isolate the GLUT4 storage compartment in order to determine the relationship of this compartment to other organelles, its components, and its presence in different cell types. A crude intracellular membrane fraction was prepared from 3T3-L1 adipocytes and subjected to **iodixanol** equilibrium sedimentation analysis. Two distinct GLUT4-containing

vesicle peaks were resolved by this procedure. The lighter of the two peaks (peak 2) was comprised of two overlapping peaks: peak 2b contained recycling endosomal markers such as the transferrin receptor (TfR), cellubrevin, and Rab4, and peak 2a was enriched in TGN markers (syntaxin 6, the cation-dependent mannose 6-phosphate receptor, sortilin, and sialyltransferase). Peak 1 contained a significant proportion of GLUT4 with a smaller but significant amount of cellubrevin and relatively little TfR. In agreement with these data, internalized transferrin (Tf) accumulated in peak 2 but not peak 1. There was a quantitatively greater loss of GLUT4 from peak 1 than from peak 2 in response to insulin stimulation. These data, combined with the observation that GLUT4 became more sensitive to ablation with Tf-horseradish peroxidase following insulin treatment, suggest that the vesicles enriched in peak 1 are highly insulin responsive. Iodixanol gradient analysis of membranes isolated from other cell types indicated that a substantial proportion of GLUT4 was targeted to peak 1 in skeletal muscle, whereas in CHO cells most of the GLUT4 was targeted to peak 2. These results indicate that in insulin-sensitive cells GLUT4 is targeted to a subpopulation of vesicles that appear, based on their protein composition, to be a derivative of the endosome. We suggest that the biogenesis of this compartment may mediate withdrawal of GLUT4 from the recycling system and provide the basis for the marked insulin responsiveness of GLUT4 that is unique to muscle and adipocytes.

3.108 Activated cardiac adenosine A_1 receptors translocate out of caveolae

Lasley, R.D., Narayan, P., Uittenbogaard, A. and Smart, E.J.
J. Biol. Chem., ***275(6)***, *4417-4421 (2000)*

The cardiac affects of the purine nucleoside, adenosine, are well known. Adenosine increases coronary blood flow, exerts direct negative chronotropic and dromotropic effects, and exerts indirect anti-adrenergic effects. These effects of adenosine are mediated via the activation of specific G protein-coupled receptors. There is increasing evidence that caveolae play a role in the compartmentalization of receptors and second messengers in the vicinity of the plasma membrane. Several reports demonstrate that G protein-coupled receptors redistribute to caveolae in response to receptor occupation. In this study, we tested the hypothesis that adenosine A_1 receptors would translocate to caveolae in the presence of agonists. Surprisingly, in unstimulated rat cardiac ventricular myocytes, 67±5% of adenosine A_1 receptors were isolated with caveolae. However, incubation with the adenosine A_1 receptor agonist 2-chlorocyclopentyladenosine induced the rapid translocation of the A_1 receptors from caveolae into non-caveolae plasma membrane, an effect that was blocked by the adenosine A_1 receptor antagonist, 8-cyclopentyl-1,3dipropylxanthine. An adenosine A_1 receptor agonist did not alter the localization of A_1 receptors to caveolae. These data suggest that the translocation of A_1 receptors out of caveolae and away from compartmentalized signaling molecules may explain why activation of ventricular myocyte A_1 receptors are associated with few direct effects.

3.109 High density lipoprotein prevents oxidized low density lipoprotein-induced inhibition of endothelial nitric-oxide synthase localization and activation in caveolae

Uittenbogaard, A., Shaul, P.W., Yuhanna, I.S., Blair, A. and Smart, E.J.
J. Biol. Chem., ***275(15)***, *11278-11283 (2000)*

Oxidized LDL (oxLDL) depletes caveolae of cholesterol, resulting in the displacement of endothelial nitric-oxide synthase (eNOS) from caveolae and impaired eNOS activation. In the present study, we determined if the class B scavenger receptors, CD36 and SR-BI, are involved in regulating nitric-oxide synthase localization and function. We demonstrate that CD36 and SR-BI are expressed in endothelial cells, co-fractionate with caveolae, and co-immuno-precipitate with caveolin-1. Co-incubation of cells with 10 *ug/ml* high density lipoprotein (HDL) prevented oxLDL induced translocation of eNOS from caveolae and restored acetylcholine-induced nitric-oxide synthase stimulation. Acetylcholine caused eNOS activation in cells incubated with 10 *ug/ml* oxLDL (10-15 thiobarbituric acid-reactive substances) and blocking antibodies to CD36, whereas cells treated with only oxLDL were unresponsive. Furthermore, CD36-blocking antibodies prevented oxLDL induced redistribution of eNOS. SR-BI-blocking antibodies were used to demonstrate that the effects of HDL are mediate by SR-BI. HDL binding to SR-BI maintained the concentration of caveola-associated cholesterol by promoting the uptake of cholesterol esters, thereby preventing oxLDL induced depletion of caveola cholesterol We conclude that CD36 mediates the effects of oxLDL on caveola composition and eNOS activation. Furthermore, HDL prevents oxLDL from decreasing the capacity for eNOS activation by preserving the cholesterol concentration in caveolae and, thereby maintaining the subcellular location of eNOS.

3.110 Gastropod mollusc aliphatic alcohol oxidase: subcellular localisation and properties

Grewal, N., Parveen, Z., Large, A., Perry, C. and Connock, M.
Comp. Biochem. Biophys., ***125****, 543-554 (2000)*

The digestive gland and other tissues of several species of terrestrial gastropod mollusc contain an aliphatic alcohol oxidase activity (EC1.1.3.13). The enzyme is FAD dependent, consumes oxygen and generates hydrogen peroxide and the corresponding aldehyde. Saturated primary alcohols arc favoured as substrates with octanol preferred with an apparent K_m of 3-4 μM**.** The activity is clearly distinguishable from previously reported molluscan aromatic alcohol oxidase (EC1.1.3.7) on the basis of FAD dependence, sensitivity to heat treatment and hi-h salt concentration and with regard to substrate preferences. The aliphatic alcohol oxidase is membrane associated and most likely localised to the endoplasmic reticulum. Extraction of membranes with 1% Igipal solubilises the enzyme in active form. This enzyme is a further example of an oxidase apparently restricted to molluscs.

3.111 *CCC1* suppresses mitochondrial damage in the yeast model of Friedreich's ataxia by limiting mitochondrial iron accumulation

Chen, O.S. and Kaplan J.
*J. Biol. Chem****., 275(11)****, 7626-7632 (2000)*

Deletion of *YFH1* in *Saccharomyces cerevisiae* leads to a loss of respiratory competence due to excessive mitochondrial iron accumulation. A suppressor screen identified a gene, *CCC1*, that maintained respiratory function in a Δ*yfh1* yeast strain regardless of extracellular iron concentration. *CCC1* expression prevented excessive mitochondrial iron accumulation by limiting mitochondrial iron uptake rather than by increasing mitochondrial iron egress. Expression of *CCC1* did not result in sequestration of iron in membranous compartments or cellular iron export. *CCC1* expression in wild type cells resulted in increased expression of the high affinity iron transport system composed of *FET3* and *FTR1*, suggesting that intracellular irons is not sensed by the iron-dependent transcription factor Aft1p. Introduction of $AFT1^{up}$, a constitutive allele of the iron transcription factor, *AFT1,* that also leads to increased high affinity iron transport did not prevent Δ*yfh1* cells from becoming respiratory-incompetent. Although the mechanism by which *CCC1* expression affects cytosolic iron is not known, the data suggest that excessive mitochondrial iron accumulation only occurs when cytosolic free iron levels are high.

3.112 Subcellular localization of presenilins: association with a unique membrane pool in cultured cells

Kim, S.H., Lah, J.J., Thinakaran, G., Levey, A. and Sisodia S.S
Neurobiol. Dis., ***7(2)****, 99-117 (2000)*

We have investigated the subcellular distribution of presinilin-1 (PS1) and presenilin-2 (PS2) in a variety of mammalian cell lines. In **Iodixanol** –based density gradients, PS1 derivatives show a biphasic distribution, cofractionating with membranes containing ER-resident proteins and an additional population of membranes with low buoyant density that do not contain markers of the Golgi complex, ERGIC, COP II vesicles, ER exit compartment, COP II receptor, SNARE, trans-Golgi network, caveolar membranes, or endocytic vesicles. Confocal immunofluorescence and immunoelectron microscopy studies fully supported the fractionation studies. These data suggest that PS1 fragments accumulate in a unique subcompartment(s) of the ER or ER to Golgi trafficking intermediates. Interestingly, the FAD-linked PS1 variants show a marked redistribution toward the heavier region of the gradient. Finally, and in contrast PS1 and PS2 fragments are detected preponderantly in more densely sedimenting membranes, suggesting that the subcellular compartments in which these molecules accumulate are distinct.

3.113 Mouse hepatitis virus replicase proteins associate with two distinct populations of intracellular membranes

Sims, A.C., Ostermann, J. and Denison, M.R.
J. Virol., ***74(12)****, 5647-5654 (2000)*

The coronavirus replicase gene (gene1) is translated into two co-amino-terminal polyproteins that are proteolytically processed to yield more than 15 mature proteins. Several gene1 proteins have been shown to localize at sites of viral RNA synthesis in the infected cell cytoplasm, notably on late endosomes at early times of infection. However, both immunofluorescence and electron microscopy studies have also detected gene 1 proteins at sites distinct from the putative sites of viral RNA synthesis or virus assembly. In this study, mouse hepatitis virus (MHV)-infected cells were fractionated and analyzed to determine if gene 1 proteins segregated to more than one membrane population. Following differential centrifugation of lysates

of MHV-infected DBT cells, gene 1 proteins as well as the structural N and M proteins were detected almost exclusively in a high-speed small membrane pellet. Following fractionation of the small membrane pellet on an **iodixanol** density gradient, the gene 1 proteins p28 and helicase cofractionated with dense membranes (1.12 to 1.13 g/ml) that also contained peak concentrations of N. In contrast, p65 and p1a-22 were detected in a distinct population of less dense membranes (1.05 to 1.09 g/ml). Viral RNA was detected in membrane fractions containing helicase, p28, and N but not fractions containing p65 and p1a-22. LAMP-1, a marker for late endosomes and lysosomes, was detected in both membrane populations. These results demonstrate that multiple gene 1 proteins segregate into two biochemically distinct but tightly associated membrane populations and that only one of the populations appears to be a site for viral RNA synthesis. The results further suggest that p28 is a component of the viral replication complex whereas the gene 1 proteins p1a-22 and p65 may serve roles during infection that are distinct from viral RNA transcription or replication.

3.114 Characterization of isolated acidocalcisomes of Trypanosoma cruzi
Scott, D.A. and Docampo, R.
J. Biol. Chem., ***275(31)***, *24215-24221 (2000)*

The acidocalcisome is an acidic calcium store in trypanosomatids, with a vacuolar-type proton-translocating pyrophosphatase (V-H^+-PPase) located in the membrane. In this paper, we describe a new method using **iodixanol** density gradients for purification of the acidocalcisomes from *Trypanosoma cruzi* epimastigotes. Pyrophosphatase assays indicated that the isolated organelle was at least 60-fold purified compared with the large organelle (10,000xg) fraction. Assays for other organelles generally indicated no enrichment in the acidocalcisome fraction; glycosomes were concentrated 5-fold. Vanadate-sensitive ATP-driven Ca^{2+} uptake (Ca^{2+}-ATPase) activity was detectable in isolated acidocalcisome, but ionophore experiments indicated that it was not acidic. However, when pyrophosphate was added, the organelle acidified and rate of Ca^{2+} uptake increased. Use of the indicator Oxonol VI showed that PPase activity generated a membrane potential. Use of sulfate or nitrate in place of chloride in the assay buffer did not affect V-H^+-ATPase activity, but there was less activity with gluconate. Organelle acidification was countered by the chloride/proton symport cycloprogidiosin. No vacuolar H^+-ATPase activity was detectable in isolated acidocalcisomes. However, immunoblots showed the presence of at least a membrane-bound V-H^+-ATPase subunit, while experiments employing permeabilized epimastigotes suggested that vacuolar H^+-ATPase and V-H^+-PPase activities are present in the same Ca^{2+}-containing compartment.

3.115 The existence of a lysosomal redox chain and the role of ubiquinone
Gille, L. and Nohl, H.
Arch. Biochem. Biophys., ***375(2)***, *347-354 (2000)*

Several studies concerning the distribution of ubiquinone (UQ) in the cell report a preferential accumulation of this biogenic quinone in mitochondria, plasma membranes, Golgi vesicles, and lysosomes. Except for mitochondria, no recent comprehensive experimental evidence exists on the particular function of UQ in these subcellular organelles. The aim of a recent study was to elucidate whether UQ is an active part of an electron-transfer system in lysosomes. In the present work, a lysosomal fraction was prepared from a light mitochondrial fraction of rat liver by isopycnic centrifugation. The purity of our preparation was verified by estimation of the respective marker enzymes. Analysis of lysosomes for putative redox carriers and redox processes in lysosomes was carried out by optical spectroscopy, HPLC, oxymetry, and ESR techniques. UQ was detected in an amount of 2.2 nmol/mg of protein in lysosomes. Furthermore, a b -type cytochrome and a flavin-adenine dinucleotide (FAD) were identified as other potential electron carriers. Since NADH was reported to serve as a substrate of UQ redox chains in plasma membranes, we also tested this reductant in lysosomes. Our experiments demonstrate a NADH-dependent reduction of UQ by two subsequent one-electron-transfer steps giving rise to the presence of ubisemiquinone and an increase of the ubiquinol pool in lysosomes. Lysosomal NADH oxidation was accompanied by an approximately equimolar oxygen consumption, suggesting that O_2 acts as a terminal acceptor of this redox chain. DMPO/OH spin adducts were detected by ESR in NADH-supplemented lysosomes, suggesting a univalent reduction of oxygen. The kinetic analysis of redox changes in lysosomes revealed that electron carriers operate in the sequence NADH > FAD > cytochrome b > ubiquinone > oxygen. By using the basic spin label TEMPAMINE, we showed that the NADH-related redox chain in lysosomes supports proton accumulation in lysosomes. In contrast to the hypothesis that UQ in lysosomes is simply a waste product of autophagy in the cell, we demonstrated that this lipophilic electron carrier is a native constituent

of a lysosomal electron transport chain, which promotes proton translocation across the lysosomal membrane.

3.116 Caveolar structure and protein sorting are maintained in NIH cells independent of glycosphingolipid depletion
Shu, L et al
Arch. Biochem. Biophys., ***373(1)****, 83-90 (2000)*

Glycosphingolipids have been proposed to be critical components of cluster lipids within cell membranes that serve as rafts for the attachment and sorting of proteins to the cell membrane. Density gradient centrifugation was used to isolate and to ascertain the lipid composition of caveolin-enriched membranes. These membranes demonstrated a significant enrichment of sphingolipids and cholesterol containing up to 20% and 30%, respectively, of the cellular glucosylceramide and lactosylceramide. A specific inhibitor of glucosylceramide synthase, d-threo-1-phenyl-2-palmitoyl-3-pyrrolidino-propanol, was used to test the hypothesis that glycosphingolipids are required for the sorting of proteins to caveolae. When NIH 3T3 cells were depleted of their glucosylceramide based glycosphingolipid mass, the caveolar structure remained intact as determined by electron microscopy and confocal microscopy. The caveolar proteins caveolin and annexin II sorted normally to caveolae, as determined by immunoblotting and confocal microscopy. When the GPI-linked protein B61 was inducibly expressed in these cells, sorting to caveolar membranes occurred normally, even in the presence of glucosylceramide depletion. These observations suggest that protein sorting to caveolae in fibroblasts occurs independently of glycosphingolipid synthesis.

3.117 Lipid rafts function in biosynthetic delivery of proteins to the cell surface in yeast
Bagnat, M., Keranen, S., Shevchenko, A., Shevchenko, A. and Simons, K.
Proc. Natl. Acad. Sci.,. USA, ***97(7)****, 3254-3259 (2000)*

Lipid rafts, formed by lateral association of sphingolipids and cholesterol, have been implicated in membrane traffic and cell signaling in mammalian cells. Sphingolipids also have been shown to play a role in protein sorting in yeast. Therefore, we wanted to investigate whether lipid rafts exist in yeast and whether these membrane microdomains have analogous function to their mammalian counterparts. We first developed a protocol for isolating detergent-insoluble glycolipid-enriched complexes (DIGs) from yeast cells. Sequencing of the major protein components of the isolated DIGs by mass spectrometry allowed us to identify, among others, Gas1p, Pma1p, and Nce2p. Using lipid biosynthetic mutants we could demonstrate that conditions that impair the synthesis of sphingolipids and ergosterol also disrupt raft association of Gas1p and Pma1p but not the secretion of acid phosphatase. That endoplasmic reticulum (ER)-to-Golgi transport of Gas1p is blocked in the sphingolipid mutant *lcb1-100* raised the question of whether proteins associate with lipid rafts in the ER or later as shown in mammalian cells. Using the sec 18-1 mutant we found that DIGs are present already in the ER. Taken together, our results suggest that lipid rafts are involved in the biosynthetic delivery of proteins to the yeast plasma membrane.

3.118 Dissecting the role of the Golgi complex and lipid rafts in biosynthetic transport of cholesterol to the cell surface
Heino, S. et al
Proc. Natl. Acad. Sci., USA, ***97(15)****, 8375-8380 (2000)*

In this study, we compared the transport of newly synthesized cholesterol with that of influenza hemagglutinin (HA) from the endoplasmic reticulum to the plasma membrane. The arrival of cholesterol on the cell surface was monitored by cyclodextrin removal, and HA transport was monitored by surface trypsinization and endoglycosidase H digestion. We found that disassembly of the Golgi complex by brefeldin A treatment resulted in partial inhibition of cholesterol transport while completely blocking HA transport. Further, microtubule depolymerization by nocodazole inhibited cholesterol and HA transport to a similar extent. When the partitioning of cholesterol into lipid rafts was analyzed, we found that newly synthesized cholesterol began to associate with low-density detergent-resistant membranes rapidly after synthesis, before it was detectable on the cell surface, and its raft association increased further upon chasing. When cholesterol transport was blocked by using 15°C incubation, the association of newly synthesized cholesterol with low-density detergent-insoluble membranes was decreased and cholesterol accumulated in a fraction with intermediate density. Our results provide evidence for the partial contribution of the Golgi complex to the transport of newly synthesized cholesterol to the cell surface and suggest that detergent-resistant membranes are involved in the process.

3.119 Palmitoylation of caveolin-1 is required for cholesterol binding, chaperone complex formation, and rapid transport of cholesterol to caveolae
Uittenbogaard, A. and Smart, E.J.
J. Biol. Chem., ***275(33)***, *25595-25599 (2000)*

We previously demonstrated that a caveolin-chaperone complex transports newly synthesized cholesterol from the endoplasmic reticulum through the cytoplasm to caveolae. Caveolin-1 has a 33-amino acid hydrophobic domain and three sites of palmitoylation in proximity to the hydrophobic domain. In the present study, we hypothesized that palmitoylation of caveolin-1 is necessary for binding of cholesterol, formation of a caveolin-chaperone transport complex, and rapid direct transport of cholesterol to caveolae. To test this hypothesis, four caveolin-1 constructs were generated that substituted an alanine for a cysteine at position 133, 143, or 156 or all three sites (triple mutant). These mutated caveolins and wild type caveolin-1 were stably expressed in the lymphoid cell line, L1210-JF which does not express caveolin-1, does not form a caveolin-chaperone complex, and does not transport newly synthesized cholesterol to caveolae. All of the caveolins were expressed and the proteins localized to plasma membrane caveolae. Wild type caveolin-1 and mutant 133 assembled into complete transport complexes and rapidly (10-20 min) transported cholesterol to caveolae. Caveolin mutants 143 and 156 did not assemble into complete transport complexes, weakly associated with cholesterol, and transported small amounts of cholesterol to caveolae. The triple mutant did not assemble into complete transport complexes and did not associate with cholesterol. We conclude that palmitoylation of caveolin-1 at positions 143 and 156 is required for cholesterol binding and transport complex formation.

3.120 Mechanism of residence of cytochrome b(5), a tail-anchored protein, in the endoplasmic reticulum
Pedrazzini, E., Villa, A., Longhi, R., Bulbarelli, A. and Borgese, N.
J. Cell Biol., ***148(5)***, *899-913 (2000)*

Endoplasmic reticulum (ER) proteins maintain their residency by static retention, dynamic retrieval, or a combination of the two. Tail-anchored proteins that contain a cytosolic domain associated with the lipid bilayer via a hydrophobic stretch close to the COOH terminus are sorted within the secretary pathway by largely unknown mechanisms. Here, we have investigated the mode of insertion in the bilayer and the intracellular trafficking of cytochrome b(5) (b[5]), taken as a model for ER-resident tail-anchored proteins. We first demonstrated that b(5) can acquire a transmembrane topology posttranslationally, and then used two tagged versions of b(5), N-glyc and O-glyc b(5), containing potential N- and O-glycosylation sites, respectively, at the COOH-terminal lumenal extremity, to discriminate between retention and retrieval mechanisms. Whereas the N-linked oligosaccharide provided no evidence for retrieval from a downstream compartment, a more stringent assay based on carbohydrate acquisition by O-glyc b(5) showed that b(5) gains access to enzymes catalyzing the first steps of O-glycosylation. These results suggest that b(5) slowly recycles between the ER and the *cis*-Golgi complex and that dynamic retrieval as well as retention are involved in sorting of tail-anchored proteins.

3.121 The role of the COOH terminus of Sec2p in the transport of post-Golgi vesicles
Elkind., N.B., Walch-Solimena, C. and Novick, P.J.
J. Cell Biol., ***149(1)***, *95-110 (2000)*

Sec2p is required for the polarized transport of secretory vesicles in *S cerevisiae*. The Sec2p NH_2 terminus encodes an exchange factor for the Rab protein Sec4p. Sec2p associates with vesicles and in Sec2p COOH-terminal mutants Sec4p and vesicles no longer accumulate at bud tips. Thus, the Sec2p COOH terminus functions in targeting vesicles, however, the mechanism of function is unknown. We found comparable exchange activity for truncated and full-length Sec2 proteins, implying that the COOH terminus does not alter the exchange rate. Full-length Sec2-GFP, similar to Sec4p, concentrates at bud tips. A COOH-terminal 58-amino acid domain is necessary but not sufficient for localization. Sec2p localization depends on actin, Myo2p and Seclp, Sec6p, and Sec9p function. Full-length, but not COOH-terminally truncated Sec2 proteins are enriched on membranes. Membrane association of full-length Sec2p is reduced in sec6-4 and sec9-4 backgrounds at 37°C but unaffected at 25°C. Taken together, these data correlate loss of localization of Sec2 proteins with reduced membrane association. In addition, Sec2p membrane attachment is substantially Sec4p independent, supporting the notion that Sec2p interacts with membranes via an unidentified Sec2p receptor, which would increase the accessibility of Sec2p exchange activity for Sec4p.

3.122 Desferrioxamine-mediated iron uptake in *Saccharomyces cerevisiae*. Evidence for two pathways of iron uptake
Yun, C-W. et al
J. Biol. Chem., ***275(14)***, *10709-10715 (2000)*

In the yeast *Saccharomyces cerevisiae*, uptake of iron is largely regulated by the transcription factor Aftl. cDNA microarrays were used to identify new iron and *AFT1*-regulated genes. Four homologous genes regulated as part of the *AFT1*-regulon (*ARN1-4*) were predicted to encode members of a subfamily of the major facilitator superfamily of transporters. These genes were predicted to encode proteins with 14 membrane spanning domains and were from 26 to 53% identical at the amino acid level. *ARN3* is identical to SIT1, which is reported to encode a ferrioxamine B permease. Deletion of *ARN3* did not prevent yeast from using ferrioxamine B as an iron source; however, deletion of *ARN3* and *FET3*, a component of the high affinity ferrous iron transport system, did prevent uptake of ferrioxamine bound iron and growth on ferrioxamine as an iron source. The siderophore-mediated transport system and the high affinity ferrous iron transport system were localized to separate cellular compartments. Epitope-tagged Arn3p was expressed in intracellular vesicles that co-sediment with the endosomal protein Pepl2. In contrast, Fet3p was expressed on the plasma membrane and was digested by extracellular proteases. These data indicate that S. cerevisiae has two pathways for ferrrioxamine-mediated iron uptake, one occurring at the plasma membrane and the other occurring in an intracellular compartment**.**

3.123 Assembly of Trp1 in a signaling complex associated with caveolin-scaffolding lipid raft domains
Lockwich, T.P. et al
J. Biol. Chem., ***275(16)***, *11934-11942 (2000)*

Trpl has been proposed as a component of the store-operated Ca^{2+} entry (SOC) channel. However, neither the molecular mechanism of SOC nor the role of Trp in this process is yet understood. We have examined possible molecular interactions involved in the regulation of SOC and Trpl and report here for the first time that Trpl is assembled in signaling complex associated with caveolin-scaffolding lipid raft domains. Endogenous hTrpl and caveolin-1 were present in low density fractions of Triton X-100-extracted human submandibular gland cell membranes. Depletion of plasma membrane cholesterol increased Triton X-100 solubility of Trpl and inhibited carbachol-stimulated Ca^{2+} signaling. Importantly, thapsigargin stimulated Ca^{2+} influx, but not internal Ca^{2+} release, and inositol 1,4,5-triphosphate (IP_3) stimulated I_{soc} were also attenuated. Furthermore, both anti-Trp1 and anti-caveolin-1 antibodies co-immunoprecipitated hTrpl, caveolin-1, $G\alpha_{q/11}$ and IP_3 receptor-type 3 (IP_3R3). These results demonstrate that caveolar microdomains provide a scaffold for (i) assembly of key Ca^{2+} signaling proteins into a complex and (ii) coordination of the molecular interactions leading to the activation of SOC. Importantly, we have shown that Trpl is also localized in this microdomain where it interacts with one or more components of this complex, including IP_3 R3. This finding is potentially important in elucidating the physiological function of Trp.

3.124 Enterotoxigenic *Escherichia coli* secretes active heat-labile enteroxin via outer membrane vesicles
Horstman, A.L. and Kuehn, M.J.
J. Biol. Chem., ***275(17)***, *12489-12496 (2000)*

Escherichia coli and other Gram-negative bacteria produce outer membrane vesicles during normal growth. Vesicles may contribute to bacterial pathogenicity by serving as vehicles for toxins to encounter host cells. Enterotoxigenic *E.coli* (ETEC) vesicles were isolated from culture supernatants and purified on velocity gradients, thereby removing any soluble proteins and contaminants from the crude preparation. Vesicle protein profiles were similar but not identical to outer membranes and differed between strains. Most vesicle proteins were resistant to dissociation, suggesting they were integral or internal. Thin layer chromatography revealed that major outer membrane lipid components are present in vesicles. Cytoplasmic membranes and cytosol were absent in vesicles; however, alkaline phosphatase and AcrA, periplasmic residents, were localized to vesicles. In addition, physiologically active heat-labile enterotoxin (LT) was associated with ETEC vesicles. LT activity correlated directly with the gradient peak of vesicles, suggesting specific association, but could be removed from vesicles under dissociating conditions. Further analysis revealed that LT is enriched in vesicles and is located both inside and on the exterior of vesicles. The distinct protein composition of ETEC vesicles and their ability to carry toxin may contribute to the pathogenicity of ETEC strains.

3.125 Biosynthesis of a major lipofuscin fluorophore in mice and humans with *ABCR*–mediated retinal and macular degeneration

Mata, N.L., Weng, J. and Travis, G.H.
*Proc. Natl. Acad. Sci. USA, **97(13)**, 7154-7159 (2000)*

Increased accumulation of lipofuscin in cells of the retinal pigment epithelium (RPE) is seen in several forms of macular degeneration, a common cause of blindness in humans. A major fluorophore of lipofuscin is the toxic *bis*-retinoid, *N*-retinylidene-*N*-retinylethanolamine (A2E). Previously, we generated mice with a knockout mutation in the *abcr* gene. This gene encodes rim protein (RmP), an ATP-binding cassette transporter in rod outer segments. Mice lacking RmP accumulate A2E in RPE cells at a greatly increased rate over controls. Here, we identify three precursors of A2E in ocular tissues from *abcr*/mice and humans with *ABCR*-mediated recessive macular degenerations. Our results corroborate the scheme proposed by C. A. Parish, M. Hashimoto, K. Nakanishi, J. Dillon & J. Sparrow *[Proc. Natl. Acad. Sci. USA* (1998) 95,14609-14613], for the biosynthesis of A2E: (i) condensation of all-*trans*-retinaldehyde *(*all-*trans*-RAL*)* with phosphatidylethanolamine to form a Schiff base; (ii) condensation of the amine product with a second all-*trans*-RAL to form a *bis*-retinoid; (iii) oxidation to yield a pyridinium salt; and (iv) hydrolysis of the phosphate ester to yield A2E. The latter two reactions probably occur within RPE phagolysosomes. As predicted by this model, formation of A2E was completely inhibited when *abcr* / mice were raised in total darkness. Also, once formed, A2E was not eliminated by the RPE. These data suggest that humans with retinal or macular degeneration caused by loss of RmP function may slow progression of their disease by limiting exposure to light. The precursors of A2E identified in this study may represent pharmacological targets for the treatment of *ABCR*-mediated macular degeneration.

3.126 Apical membrane targeting of Nedd4 is mediated by an association of its C2 domain with annexin XIIIb

Plant PJ. et al
*J. Cell Biol., **149(7)**, 1473-1483 (2000).*

Nedd4 is a ubiquitin protein ligase (E3) containing a C2 domain, three or four WW domains, and a ubiquitin ligase HECT domain. We have shown previously that the C2 domain of Nedd4 is responsible for its Ca2+-dependent targeting to the plasma membrane, particularly the apical region of epithelial MDCK cells. To investigate this apical preference, we searched for Nedd4-C2 domain-interacting proteins that might be involved in targeting Nedd4 to the apical surface. Using immobilized Nedd4-C2 domain to trap interacting proteins from MDCK cell lysate, we isolated, in the presence of Ca2+, a ~35-40-kD protein that we identified as annexin XIII using mass spectrometry. Annexin XIII has two known isoforms, a and b, that are apically localized, although XIIIa is also found in the basolateral compartment. In vitro binding and coprecipitation experiments showed that the Nedd4-C2 domain interacts with both annexin XIIIa and b in the presence of Ca2+, and the interaction is direct and optimal at 1 μM Ca2+. Immunofluorescence and immunogold electron microscopy revealed colocalization of Nedd4 and annexin XIIIb in apical carriers and at the apical plasma membrane. Moreover, we show that Nedd4 associates with raft lipid microdomains in a Ca2+ -dependent manner, as determined by detergent extraction and floatation assays. These results suggest that the apical membrane localization of Nedd4 is mediated by an association of its C2 domain with the apically targeted annexin XIIIb.

3.127 Mutation of conserved aspartates affects maturation of both aspartate mutant and endogenous presenilin 1 and presenilin 2 complexes
Yu, G. et al
J. Biol. Chem., ***275(35)***, *27348-27353 (2000)*

Presenilin (PS1 and PS2) holoproteins are transiently incorporated into low molecular weight (MW complexes. During subsequent incorporation into a higher MW complex, they undergo endoproteolysis to generate stable N- and C-terminal fragments. Mutation of either of two conserved aspartate residues in transmembrane domains inhibits both presenilin-endoproteolysis and the proteolytic processing of β-amyloid precursor protein and Notch. We show that although PS1/PS2 endoproteolysis is not required for inclusion into the higher MW N- and C-terminal fragment-containing complex, aspartate mutant holoprotein presenilins are not incorporated into the high MW complexes. Aspartate mutant presenilin holoproteins also preclude entry of endogenous wild type PS1/PS2 into the high MW complexes but do not affect the incorporation of wild type holoproteins into lower MW holoprotein complexes. These data suggest that the loss of function effects of the aspartate mutants result in altered PS complex maturation and argue that the functional presenilin moieties are contained in the high molecular weight complexes.

3.128 ^{31}P NMR spectroscopy of *Trypanosoma brucei, Trypanosoma cruzi*, and *Leishmania major*
Moreno, B. et al
J. Biol. Chem., ***275(37)***, *28356-28362 (2000)*

High resolution ^{31}P nuclear magnetic resonance spectra at 303.6 MHz (corresponding to a ^{1}H resonance frequency of 750 MHz) have been obtained of perchloric acid extracts of *Trypanosoma brucei, Trypanosoma cruzi* and *Leishmania major*, the causative agents of African sleeping sickness, Chagas'disease, and leishmaniasis. Essentially complete assignments have been made based on chemical shifts and by direct addition of authentic reference compounds. The results indicate the presence of high levels of short chain condensed polyphosphates: di-, tri-, tetra-, and pentapolyphosphate. ^{31}P NMR spectra of purified *T. brucei, T. cruzi* and *L. major* acidocalcisomes, calcium and phosphorus storage organelles, indicate that polyphosphates are abundant in these organelles and have an average chain length of 3.11-3.39 phosphates. In the context of the recent discovery of several pyrophosphate-utilizing enzymes in trypanosomatids, the presence of these inorganic polyphosphates implies a critical role for these molecules in these parasites and a potential new route to chemotherapy.

3.129 Epidermal growth factor-mediated caveolin recruitment to early endosomes and MAPK activation
Pol, A., Lu, A., Pons, M., Peiro, S. and Enrich, C.
J. Biol. Chem., ***275(39)***, *30566-30572 (2000)*

The endocytic compartment of eukaryotic cells is a complex intracellular structure involved in sorting, processing, and degradation of a great variety of internalized molecules. Recently, the uptake through caveolae has emerged as an alternative internalization pathway, which seems to be directly related with some signal transduction pathways. However, the mechanisms, molecules, and structures regulating the transport of caveolin from the cell surface into the endocytic compartment are largely unknown. In this study, normal quiescent fibroblasts (normal rat kidney (NRK)) were used to demonstrate that epidermal growth factor causes partial redistribution of caveolin from the cell surface into a cellubrevin early endocytic compartment. Treatment of NRK cells with cytochalasin D or latrunculin A inhibit this pathway and the concomitant activation of Mek and mitotic-activated protein (MAP) kinase; however, if cells were pre-treated with filipin, cytochalasin D does not inhibit the phosphorylation of MAP kinase induced by epidermal growth factor. From these results we conclude that in NRK cells the intact actin cytoskeleton is necessary for the EGF-mediated transport of caveolin from the cell surface into the early endocytic compartment and the activation of MAP kinase pathway.

3.130 Dystrophin associates with a caveolae of rat cardiac myocytes

Doyle, D.D. et al

*Circulation Res., **87**, 480-488 (2000)*

The possibility of an interaction between the cytoskeletal protein dystrophin and cell surface caveolae in the mammalian myocardium was investigated by several techniques. Caveolin (cav)-3-enriched, detergent-insoluble membranes isolated from purified ventricular sarcolemma by density-gradient fractionation were found to contain dystrophin and dystroglycan. Further purification of cav-3-containing membranes by immunoprecipitation using anti-cav-3-coated magnetic beads yielded dystrophin but not always dystroglycan. Electron microscopic analysis of precipitated material revealed caveola-sized vesicular profiles that could be double-labeled with anti-dystrophin and anti-cav-3 antibodies. In contrast, immunoprecipitation of membranes with anti-dystrophin-coated beads yielded both cav-3 and dystroglycan. Electron microscopic analysis of this material showed heterogeneous membrane profiles, some of which could be decorated with anti-cav-3 antibodies. To confirm that dystrophin and cav-3 were closely associated in cardiac myocytes, we verified that dystrophin was also present in immunoprecipitated cav-3-containing membranes from detergent extracts, as well as in sonicated extracts of purified ventricular myocytes. Confocal immunofluorescence microscopy of ventricular and atrial cardiac myocytes showed that the cellular distributions of cav-3 and dystrophin partially overlapped. Immuno-electron micrographs of thin sections of rat atrial myocytes revealed a fraction of dystrophin molecules that are in apparently close apposition to caveolae. These results suggest that a subpopulation of dystrophin molecules interacts with cardiac myocyte caveolae in vivo and that some of the dystrophin is engaged in linking cav-3 with the dystroglycan complex.

3.131 Chemical stimulation of synaptosomes modulates α-Ca^{2+}/calmodulin-dependent protein kinase II mRNA association to polysomes

Bagni, C., Mannucci, L., Dotti, C.G. and Amaldi, F.

*J. Neurosci., **20 RC76**, 1-6 (2000)*

The presence of specific mRNAs in dendrites and at synapses is well established, but a direct and reliable demonstration that they are associated with polysomes is still missing. To address this point we analyzed the polysomal association of the mRNAs for the α-subunit of Ca^{2+} /calmodulin-dependent protein kinase II (α-CaMKII), for type 1 inositol 1,4,5-trisphosphate receptor (InsP3Rl) and for the activity-regulated cytoskeleton-associated protein (Arc) in a synaptosomal preparation devoid of contaminating material from neuronal and glial perikarya. We show that a fraction of α-CaMKII, InsP3Rl, and Arc mRNAs present in synaptosomes is indeed associated with polysomes. Moreover, we show that polysomal association of α-CaMKII mRNA, but not InsP3Rl and Arc mRNAs, increases with depolarization of the synaptosomal membrane. Finally, we show that the synthesis of α-CaMKII protein increases with stimulation. Dendritic mRNA recruitment onto polysomes in response to synaptic stimulation might represent one of the mechanisms underlying the processes of learning and memory.

3.132 Mutant presenilin 1 increases the levels of Alzheimer amyloid β-peptide Aβ42 in late compartments of the constitutive secretory pathway
Petanceska, S., Seeger, M., Checler, F. and Gandy, S.
*J. Neurochem., **74**, 1878-1884 (2000)*

Mutations in the presenilin 1 (PS1) gene are associated with autosomal dominant, early-onset, familial Alzheimer's disease and result in increased release of the hyperaggregatable 42-amino acid form of the amyloid β-peptide (Aβ42). To determine which subcellular compartments are potential source(s) of released Aβ42, we compared the levels and spatial segregation of intracellular Aβ40 and Aβ42 peptides between N2a neuroblastoma cells doubly transfected with the "Swedish" familial Alzheimer's disease-linked amyloid precursor protein variant and either wild-type PS1 ($PS1^{wt}$) or familial Alzheimer's disease-linked Δ9 mutant PS1 ($PS1^{\Delta 9}$). As expected, $PSl^{\Delta 9}$-expressing cells had dramatically higher levels of intracellular Aβ42 than did cells expressing $PS1^{wt}$. However, the highest levels of Aβ42 colocalized not with endoplasmic reticulum or Golgi markers but with rab8, a marker for trans-Golgi network (TGN)-to-plasma membrane (PM) transport vesicles. We show that PS1 mutants are capable of causing accumulation of Aβ42 in late compartments of the secretary pathway, generating there a readily releasable source of Aβ42. Our findings indicate that PS1 "bioactivity" localizes to the vicinity of the TGN and/or PM and reconcile the apparent discrepancy between the preponderant concentration of PS1 protein in proximal compartments of the secretary pathway and the recent findings that PS1 "bioactivity" can control γ-secretase-like processing of another transmembrane substrate, Notch, at or near the PM.

3.133 Golgi targeting of the GLUT1 glucose transporter in lactating mouse mammary gland
Nemeth, B.A., Tsang, S.W.Y., Geske, R.S. and Haney, P.
*Pediatr Res., **47**, 444-450 (2000)*

Lactose, the major carbohydrate of human milk, is synthesized in the Golgi from glucose and UDP-galactose. The lactating mammary gland is unique in its requirement for the transport of glucose into Golgi. Glucose transporter-1 (GLUT1) is the only isoform of the glucose transporter family expressed in mammary gland. In most cells, GLUT1 is localized to the plasma membrane and is responsible for basal glucose uptake; in no other cell type is GLUT1 a Golgi resident. To test the hypothesis that GLUT1 is targeted to Golgi during lactation, the amount and subcellular distribution of GLUT1 were examined in mouse mammary gland at different developmental stages. Methods including immunohistochemistry, immunofluorescence, subcellular fractionation, density gradient centrifugation, and Western blotting yielded consistent results. In virgins, GLUT1 expression was limited to plasma membrane of epithelial cells. In late pregnant mice, GLUT1 expression was increased with targeting primarily to basolateral plasma membrane but also with some intracellular signal. During lactation, GLUT1 expression was further increased, and targeting to Golgi, demonstrated by colocalization with the 110-kD coatomer-associated protein β-COP, predominated. Removal of pups 18 d after delivery resulted in retargeting of GLUT1 from Golgi to plasma membrane and a decline in total cellular GLUT1 within 3 h. In mice undergoing natural weaning, GLUT1 expression declined. Changes in the amount and targeting of GLUT1 during mammary gland development are consistent with a key role for GLUT1 in supplying substrate for lactose synthesis and milk production.

3.134 Membrane raft microdomains mediate lateral assemblies for HIV-1 infection
Manes, S. et al
*EMBO reports, **1(2),** 190-196 (2000)*

HIV-1 infection triggers lateral membrane diffusion following interaction of the viral envelope with cell surface receptors. We show that these membrane changes are necessary for infection, as initial gpl2O-CD4 engagement leads to redistribution and clustering of membrane microdomains, enabling subsequent interaction of this complex with HIV-1 co-receptors. Disruption of cell membrane rafts by cholesterol depletion before viral exposure inhibits entry by both X4 and R5 strains of HIV-1, although viral replication in infected cells is unaffected by this treatment. This inhibitory effect is fully reversed by cholesterol replenishment of the cell membrane. These results indicate a general mechanism for HIV-1 envelope glycoprotein-mediated fusion by reorganization of membrane microdomains in the target cell, and offer new strategies for preventing HIV-1 infection.

3.135 Subcellular organization of bile acid amidation in human liver: a key in regulating the biosynthesis of bile salts

Solaas, K., Ulvestad, A., Soreide, O. and Kase, B.F.
*J. Lipid Res., **41**, 1154-1162 (2000)*

To extend our knowledge of how the synthesis of free bile acids and bile salts is related within the hepatocytes, bile acid-CoA:amino acid N-acyltransferase and bile acid-CoA thioesterase activities were measured in subcellular fractions of human liver homogenates. Some bile acids, both conjugated and unconjugated, have been reported to be natural ligands for the farnesoid X receptor (FXR), an orphan nuclear receptor. The conversion of [^{14}C]choloyl-CoA and [^{14}C]chenodeoxycholoyl-CoA into the corresponding tauro- and glyco-bile acids or the free bile acids was measured after high-pressure liquid radiochromatography. There was an enrichment of the N-acyltransferase in the cytosolic and the peroxisomal fraction. Bile acid-CoA thioesterase activities were enriched in the cytosolic, peroxisomal, and mitochondrial fractions. The highest amidation activities of both choloyl-CoA and chenodeoxycholoyl-CoA were found in the peroxisomal fraction (15-58 nmol/mg protein/min). The K_m, was higher for glycine than taurine both in cytosol and the peroxisomal fractions These results show that the peroxisomal de novo synthesis of bile acids is rate limiting for peroxisomal amidation, and the microsomal bile acid-CoA synthetase is rate limiting for the cytosolic amidation. The peroxisomal location may explain the predominance of glyco-bile acids in human bile. Both a cytosolic and a peroxisomal bile acid-CoA thioesterase may, influence the intracellular levels of free and conjugated bile acids.

3.136 Human bleomycin hydrolase regulates the secretion of amyloid precursor protein

Lefterov, I.M., Koldamova, R.P. and Lazo, J.S.
*FASEB J., **14**, 1837-1847 (2000)*

Human bleomycin hydrolase (hBH) is a neutral cysteine protease genetically associated with increased risk for Alzheimer disease. We show here that ectopic expression of hBH in 293APPwt and CHOAPPsw cells altered the processing of amyloid precursor protein (APP) and increased significantly the release of its proteolytic fragment, β amyloid (Aβ). We also found that hBH interacted and colocalized with APP as determined by subcellular fractionation, *in vitro* binding assay, and confocal immunolocalization. Metabolic labeling and pulse-chase experiments, showed that ectopic hBH expression increased secretion of soluble APPα/β products without changing the half-life of cellular APP. We also observed that this increased Aβ secretion was independent of hBH isoforms. Our findings suggest a regulatory role for hBH in APP processing pathways.

3.137 Identification, purification and characterization of an acetoacetyl-CoA thiolase from rat liver peroxisomes

Antonenkov, V.D., Croes, K., Waelkens, E., Van Veldhoven, P.P. and Mannaerts, G.P.
*Eur. J. Biochem., **267**, 2981-2990 (2000)*

Acetoacetyl-CoA specific thiolases catalyse the cleavage of acetoacetyl-CoA into two molecules of acetyl-CoA and the synthesis (reverse reaction) of acetoacetyl-CoA. The formation of acetoacetyl-CoA is the first step in cholesterol and ketone body synthesis. In this report we describe the identification of a novel acetoacetyl-CoA thiolase and its purification from isolated rat liver peroxisomes by column chromatography. The enzyme, which is a homotetramer with a subunit molecular mass of 42 kDa, could be distinguished from the cytosolic and mitochondrial acetoacetyl-CoA thiolases by its chromatographic behaviour, kinetic characteristics and partial internal amino-acid sequences. The enzyme did not catalyse the cleavage of medium or long chain 3-oxoacyl-CoAs. The enzyme cross-reacted with polyclonal antibodies raised against cytosolic acetoacetyl-CoA thiolase. The latter property was exploited to confirm the peroxisomal localization of the novel thiolase in subcellular fractionation experiments.
The peroxisomal acetoacetyl-CoA thiolase most probably catalyses the first reaction in peroxisomal cholesterol and dolichol synthesis. In addition, its presence in peroxisomes along with the other enzymes of the ketogenic pathway indicates that the ketogenic potential of peroxisomes needs to be re-evaluated.

3.138 Human oxytocin receptors in cholesterol-rich vs. cholesterol-poor microdomains of the plasma membrane

Gimpl, G. and Fahrenholz, F.
*Eur. J. Biochem., **267**, 2483-2497 (2000)*

We analyzed the properties of a G protein-coupled receptor localized in cholesterol-poor vs. cholesterol-rich microdomains of the plasma membrane. For this purpose, the human oxytocin receptor, which is very sensitive against alterations of the membrane cholesterol level, was stably expressed in HEK293 cells, To calculate the total number of receptors independent of ligand binding studies, the oxytocin receptor was tagged with an enhanced green fluorescent protein (EGFP) which did not change the functional properties of the receptor. Only 1% of the oxytocin receptors were present in cholesterol-rich detergent-insoluble domains. In contrast, employing a detergent-free fractionation scheme that preserves the functional activity of the receptor, we detected 10-15% of the receptors in cholesterol-rich low-density membranes and therein the high-affinity state receptors were twofold enriched. In cholesterol-poor vs. cholesterol-rich domains, high-affinity oxytocin receptors behaved similar with respect to their agonist binding kinetics and GTP sensitivity. However, high-affinity oxytocin receptors localized in cholesterol-rich low-density membranes showed a markedly enhanced (t, ≈ threefold) stability at 37°C as compared with the oxytocin receptors localized in the cholesterol-poor high-density membranes. Addition of cholesterol to the high-density membranes fully protected the oxytocin receptors against loss of function. The importance of cholesterol to stabilize the oxytocin receptor was supported in experiments with solubilized receptors. Cholesterol markedly delayed the inactivation of oxytocin receptors solubilized with Chapso. In conclusion, the data of this report suggest that functional properties of heptahelical receptor proteins could differ in dependence of their localization in different membrane microdomains.

3.139 Involvement of gangliosides in GPI-anchored neuronal cell adhesion molecule TAG-1 signaling in lipid rafts

Kasahara, K. et al
*J. Biol. Chem., **275(44)**, 34701-34709 (2000)*

The association of ganglioside GD3 with TAG-1, a glycosylphosphatidylinositol (GPI)-anchored neuronal cell adhesion molecule, was examined by coimmunoprecipitation experiments. Previously, we have shown that the anti-ganglioside GD3 antibody (R24) immunoprecipitated the src-family kinase Lyn from the rat cerebellum, and R24 treatment of primary cerebellar cultures induced Lyn activation and rapid tyrosine phosphorylation of an 80-kDa protein (p80). We now report that R24 coimmunoprecipitates a 135-kDa protein (p135) from primary cerebellar cultures. Treatment with phosphatidylinositol-specific phospholipase C revealed that p135 was GPI-anchored to the membrane. It was identified as TAG-1 by sequential immunoprecipitation with an anti-TAG-1 antibody. Antibody-mediated crosslinking of TAG-1 induced Lyn activation and rapid tyrosine phosphorylation of p80. Selective inhibitor for src-family kinases reduced the tyrosine phosphorylation of p80. Sucrose density gradient analysis revealed that the TAG-1 and tyrosine-phosphorylated p80 in cerebellar cultures were present in the lipid raft fraction. These data show that TAG-1 transduces signals via Lyn to p80 in the lipid rafts of the cerebellum. Furthermore, degradation of cell-surface glycosphingolipids by endoglycoceramidase induced an alteration of TAG-1 distribution on an **OptiPrep** gradient and reduced the TAG-1 mediated Lyn activation and tyrosine phosphorylation of p80. These observations suggest that glycosphingolipids are involved in TAG-1 mediated signaling in lipid rafts.

3.140 Presence of oxidized cholesterol in caveolae uncouples active platelet-derived growth factor receptors from tyrosine kinase substrates

Liu, P., Wang, P-y., Michaely, P., Zhu, M. and Anderson, R.G.W.
*J. Biol. Chem., **275(41)**, 31648-31654 (2000)*

Platelet-derived growth factor receptor β (PDGFRβ) in fibroblasts is concentrated in caveolae where it controls the tyrosine phosphorylation of multiple proteins. Caveolae are enriched in cholesterol and sphingolipids, but the role of these lipids in PDGFR signal transduction is unknown. We report that introduction of cholest-4-en-3-one into caveolae membranes uncouples PDGFR autophosphorylation from tyrosine phosphorylation of neighboring proteins. Cholest-4-en-3-one appears to interfere with the normal interaction between PDGFR and its partners. The results suggest that tightly packed caveolae lipids form a membrane platform that functions as a lipid scaffold for organizing the molecular interactions of multiple signaling pathways.

3.141 Huntingtin expression stimulates endosomal-lysosomal activity, endosome tubulation and autophagy
Kegel, K.B. et al
J. Neurosci., ***20(19)***, *7268-7278 (2000)*

An expansion of polyglutamines in the N terminus of huntingtin causes Huntington's disease (HD) and results in the accrual of mutant protein in the nucleus and cytoplasm of affected neurons. How mutant huntingtin causes neurons to die is unclear, but some recent observations suggest that an autophagic process may occur. We showed previously that huntingtin markedly accumulates in endosomal-lysosomal organelles of affected HD neurons and, when exogenously expressed in clonal striatal neurons, huntingtin appears in cytoplasmic vacuoles causing cells to shrink. Here we show that the huntingtin-enriched cytoplasmic vacuoles formed *in vitro* internalized the lysosomal enzyme cathepsin D in proportion to the polyglutamine-length in huntingtin. Huntingtin-labeled vacuoles displayed the ultrastructural features of early and late autophagosomes (autolysosomes), had little or no overlap with ubiquitin, proteasome, and heat shock protein 70/heat shock cognate 70 immunoreactivities, and altered the arrangement of Golgi membranes mitochondria, and nuclear membranes. Neurons with excess cytoplasmic huntingtin also exhibited increased tubulation of endosomal membranes. Exogenously expressed human full-length wild-type and mutant huntingtin codistributed with endogenous mouse huntingtin in soluble and membrane fractions, whereas human N-terminal huntingtin products were found only in membrane fractions that contained lysosomal organelles. We speculate that mutant huntingtin accumulation in HD activates the endosomal-lysosomal system, which contributes to huntingtin proteolysis and to an autophagic process of cell death.

3.142 The human DIMINUTO/DWARF1 homolog seladin-1 confers resistance to Alzheimer's disease-associated neurodegeneration and oxidative stress
Greeve, I. et al
J. Neurosci., ***20(19)***, *7345-7352 (2000)*

In Alzheimer's disease (AD) brains, selected populations of neurons degenerate heavily, whereas others are frequently spared from degeneration. To address the cellular basis for this selective vulnerability of neurons in distinct brain regions, we compared gene expression between the severely affected inferior temporal lobes and the mostly unaffected fronto-parietal cortices by using an mRNA differential display. We identified *seladin-1*, a novel gene, which was down regulated in large pyramidal neurons in vulnerable regions in AD but not control brains. Seladin- 1 is a human homolog of the *DIMINUTO/DWARF1* gene described in plants and *Caenorhabditis elegans*. Its sequence shares similarities with flavin-adenin-dinucleotide (FAD)-dependent oxidoreductases. In human control brain, *seladin-1* was highly expressed in almost all neurons. In PC12 cell clones that were selected for resistance against AD-associated amyloid-β peptide (Aβ)-induced toxicity, both mRNA and protein levels of seladin-1 were approximately threefold higher as compared with the non-resistant wild-type cells. Functional expression of seladin-1 in human neuroglioma H4 cells resulted in the inhibition of caspase 3 activation after either Aβ-mediated toxicity or oxidative stress and protected the cells from apoptotic cell death. In apoptotic cells, however, endogenous seladin-1 was cleaved to a 40 kDa derivative in a caspase-dependent manner. These results establish that seladin-1 is an important factor for the protection of cells against Aβ toxicity and oxidative stress, and they suggest that seladin-1 may be involved in the regulation of cell survival and death, Decreased expression of seladin-1 in specific neurons may be a cause for selective vulnerability in AD.

3.143 Carboxyl-terminal fragments of Alzheimer β-amyloid precursor protein accumulate in restricted and unpredicted intracellular compartments in presenilin 1 deficient cells
Chen, F. et al
J. Biol. Chem., ***275***, *36794-36802 (2000)*

Absence of functional presenilin 1 (PS1) protein leads to loss of γ-secretase cleavage of the amyloid precursor protein (βAPP), resulting in a dramatic reduction in amyloid β peptide (Aβ) production and accumulation of α- or β-secretase-cleaved C-terminal fragments of βAPP (α- or β-CTFs). The major C-terminal fragment (CTF) in brain was identified as βAPP-CTF-(11-98), which is consistent with the observation that cultured neurons generate primarily Aβ(11-40). In $PS1^{-/-}$ murine neurons and fibroblasts expressing the loss-of-function $PS1_{D385A}$ mutant, CTFs accumulated in the endoplasmic reticulum, Golgi, and lysosomes, but not late endosomes. There were some subtle differences in the subcellular distribution of CTFs in $PS1^{-/-}$ neurons as compared to $PS1_{D385A}$ mutant fibroblasts. However, there was no obvious redistribution of full-length βAPP or of markers of other organelles in either mutant. Blockade of endoplasmic reticulum-to-Golgi trafficking indicated that in $PS1^{-/-}$ neurons (as in normal cells) trafficking of βAPP to the Golgi compartment is necessary before α-and β-secretase cleavage occurs. Thus, while we cannot exclude a specific role for PS1 in trafficking of CTFs, these data argue against a major role in general protein trafficking. These results are more compatible with a role for PS1 either as the actual γ-secretase catalytic activity or in other functions indirectly related to γ-secretase catalysis (e.g. an activator of γ-secretase, a substrate-adaptor for γ-secretase, or delivery of γ-secretase to βAPP-containing compartments.

3.144 Differential targeting of β-adrenergic receptor subtypes and adenyl cyclase to cardiomyocyte caveolae: A mechanism to functionally regulate the cAMP signaling pathway
Rybin, V.O., Xu, X., Lisanti, M.P. and Steinberg, S.F.
J. Biol. Chem., ***275(52)***, *41447-41457(2000)*

Differential modes for β_1 and β_2-adrenergic receptor (AR) regulation of adenylyl cyclase in cardiomyocytes is most consistent with spatial regulation in microdomains of the plasma membrane. This study examines whether caveolae represent specialized subdomains that concentrate and organize these moieties in cardiomyocytes. Caveolae from quiescent rat ventricular cardiomyocytes are highly enriched in β_2-ARs, $G\alpha_i$, protein kinase A, RIIα subunits, caveolin-3, and flotillins (caveolin functional homologues); β_1-ARs, m_2-muscarinic cholinergic receptors, $G\alpha_s$ and cardiac types V/VI adenylyl cyclase distribute between caveolae and other cell fractions, whereas protein kinase A RIα subunits, G protein-coupled receptor kinase-2, and clathrin are largely excluded from caveolae. Cell surface β_2-ARs localize to caveolae in cardiomyocytes and cardiac fibroblasts (with markedly different β_2-AR expression levels), indicating that the fidelity of β_2-AR targeting to caveolae is maintained over a physiologic range of β_2-AR expression. In cardiomyocytes, agonist stimulation leads to a marked decline in the abundance of β_2-ARs (but not β_1-ARs) in caveolae. Other studies show co-immunoprecipitation of cardiomyocytes adenylyl cyclase V/VI and caveolin-3, suggesting their *in vivo* association. However, caveolin is not required for adenylyl cyclase targeting to low density membranes, since adenylyl cyclase targets to low buoyant density membrane fractions of HEK cells that lack prototypical caveolins. Nevertheless, cholesterol depletion with cyclodextrin augments agonist-stimulated cAMP accumulation, indicating that caveolae function as negative regulators of cAMP accumulation. The inhibitory interaction between caveolae and the cAMP signaling pathway as well as domain-specific differences in the stoichiometry of individual elements in the β-AR signaling cascade represent important modifiers of cAMP-dependent signaling in the heart.

3.145 Selective accumulation of raft-associated membrane protein LAT in T cell receptor signaling assemblies

Harder, T. and Kuhn, M.
*J. Cell Biol., **151(2)**, 199-207 (2000)*

Activation of T cell antigen receptor (TCR) induces tyrosine phosphorylations that mediate the assembly of signaling protein complexes. Moreover, cholesterol-sphingolipid raft membrane domains have been implicated to play a role in TCR signal transduction. Here, we studied the assembly of TCR with signal transduction proteins and raft markers in plasma membrane subdomains of Jurkat T leukemic cells. We employed a novel method to immunoisolate plasma membrane subfragments that were highly concentrated in activated TCR-CD3 complexes and associated signaling proteins. We found that the raft transmembrane protein linker for activation of T cells (LAT), but not a palmitoylation-deficient non-raft LAT mutant, strongly accumulated in TCR-enriched immunoisolates in a tyrosine phosphorylation-dependent manner. In contrast, other raft-associated molecules, including protein tyrosine kinases Lek and Fyn, GM1, and cholesterol, were not highly concentrated in TCR-enriched plasma membrane immunoisolates. Many downstream signaling proteins coisolated with the TCR/LAT-enriched plasma membrane fragments, suggesting that LAT/ TCR assemblies form a structural scaffold for TCR signal transduction proteins. Our results indicate that TCR signaling assemblies in plasma membrane subdomains, rather than generally concentrating raft-associated membrane proteins and lipids, form by a selective protein-mediated anchoring of the raft membrane protein LAT in vicinity of TCR.

3.146 Presenilin complexes with the C-terminal fragments of amyloid precursor protein at the sites of amyloid β-protein generation

Xia, W. et al
*Proc. Natl. Acad. Sci., **97(16)**, 9299-9304 (2000)*

An unusual intramembranous cleavage of the β-amyloid precursor protein (APP) by γ-secretase is the final step in the generation of amyloid β-peptide (Aβ). Two conserved aspartates in transmembrane (TM) domains 6 and 7 of presenilin (PS) 1 are required for Aβ production by γ-secretase. Here we report that the APP C-terminal fragments, C83 and C99, which are the direct substrates of γ-secretase, can be coimmunoprecipitated with both PS1 and PS2. PS/C83 complexes were detected in cells expressing endogenous levels of PS. The complexes accumulate when γ-secretase is inactivated either pharmacologically or by mutating the PS aspartates. PS1/ C83 and PS1/C99 complexes were detected in Golgi-rich and trans-Golgi network-rich vesicle fractions. In contrast, complexes of PS1 with APP holoprotein, which is not the immediate substrate of γ-secretase, occurred earlier in endoplasmic reticulum-rich vesicles. The major portion of intracellular Aβ at steady state was found in the same Golgi/trans-Golgi network-rich vesicles, and Aβ levels in these fractions were markedly reduced when either PS1 TM aspartate was mutated to alanine. Furthermore, *de novo* generation of Aβ in a cell-free microsomal reaction occurred specifically in these same vesicle fractions and was markedly inhibited by mutating either TM aspartate. Thus, PSs are complexed with the γ-secretase substrates C83 and C99 in the subcellular locations where Aβ is generated, indicating that PSs are directly involved in the pathogenically critical intramembranous proteolysis of APP.

3.147 Long-term insulin treatment of 3T3-L1 adipocytes results in mis-targeting of GLUT4: implications for insulin-stimulated glucose transport

Maier, V.H. and Gould G.W.

*Diabetologia, **43(10)**, 1273-1281 (2000)*

Aimslhypothesis. Insulin stimulates glucose transport in adipose and muscle tissue by the translocation of a specialised pool of intracellular GLUT4-containing vesicles to the cell surface. It is well established that defective insulin-stimulated GLUT4 translocation is associated with insulin resistance. Long-term insulin treatment (500 nmol/l for 24 h) of 3T3-Ll adipocytes has previously been shown to decrease cellular GLUT4 content and reduce insulin-stimulated GLUT4 translocation. Here, we test the hypothesis that the insulin resistance observed after long-term insulin treatment arises by the selective loss of GLUT4 from a specific intracellular compartment.

Methods Using **iodixanol** gradient centrifugation we have separated intracellular GLUT4 containing membranes into two distinct populations corresponding to recycling endosomes and a distinct intracellular compartment, which probably represents GLUT4 storage vesicles (GSVs).

Results. A short-term insulin stimulation reduced the content of GLUT4 in the GSV fraction (51 ± 3.5 %) with only a modest decrease from the endosomal fraction (23 ± 2.6 %). Long-term insulin treatment decreased cellular GLUT4 content by about 40 % and diminished the ability of a short-term insulin challenge to promote GLUT4 translocation. We further show that this depletion of cellular GLUT4 is selectively from the GSV fraction (68 ± 7 % decrease compared to untreated cells).

Conclusions/interpretation. Such data argue that long-term insulin treatment results in the mistargeting of GLUT4 such that it no longer accesses the GSV compartment. These data imply that defective targeting of GLUT4 away from the GSV compartment plays an important role in the aetiology of insulin resistance.

3.148 Assembly of myelin by association of proteolipid protein with cholesterol and galactosylceramide-rich membrane domains

Simons, M., Kramer, E-M., Thiele, C., Stoffel, W. And Trotter, J.

*J. Cell Biol., **151(1)**, 143-153 (2000)*

Myelin is a specialized membrane enriched in glycosphingolipids and cholesterol that contains a limited spectrum of proteins. We investigated the assembly of myelin components by oligodendrocytes and analyzed the role of lipid-protein interactions in this process. Proteolipid protein (PLP), the major myelin protein, was recovered from cultured oligodendrocytes from a lower-density CHAPS-insoluble membrane fraction (CIMF) enriched in myelin lipids. PLP associated with the CIMF after leaving the endoplasmic reticulum but before exiting the Golgi apparatus, suggesting that myelin lipid and protein components assemble in the Golgi complex. The specific association of PLP with myelin lipids in CIMF was supported by the finding that it was efficiently cross-linked to photoactivable cholesterol, but not to phosphatidylcholine, which is underrepresented in both myelin and CIMF: Furthermore, depletion of cholesterol or inhibition of sphingolipid synthesis in oligodendrocytes abolished the association of PLP with CIMF. Thus PLP may be recruited to myelin rafts, represented by CIMF, via lipid-protein interactions. In contrast to oligodendrocytes, after transfection in BHK cells, PLP is absent from isolated CIMF, suggesting that PLP requires specific lipids for raft association. In mice deficient in the enzyme ceramide galactosyl transferase, which cannot synthesize the main myelin glycophingolipids, a large fraction of PLP no longer associates with rafts. Formation of a cholesterol- and galactosylceramide-rich membrane domain (myelin rafts) may be critical for the sorting of PLP and assembly of myelin in oligodendrocytes.

3.149 Intracellular events in the assembly of chylomicrons in rabbit enterocytes

Cartwright, I.J., Plonne, D. and Higgins, J.A.
*J. Lipid Res., **41**, 1728-1739 (2000)*

The aim of this study was to determine the intracellular events in chylomicron assembly in adult villus enterocytes. We have used novel methods for separation of the intracellular components of the secretory compartment [rough and smooth endoplasmic reticulum (RER and SER), respectively) and Golgi], and their membrane and luminal components, from villus enterocytes isolated from rabbit small intestine. The steady state composition of the components of the secretory compartment and the intracellular pools of newly synthesized. Apolipoprotein B-48 (apoB-48) and triacylglycerol (TAG) was determined. The observations indicate that the SER is the main site of the TAG synthesis and of chylomicron assembly. Newly synthesized apoB-48 and TAG accumulate in the SER membrane and are transferred into the lumen in a microsomal triglyceride transfer protein-dependent step. In enterocytes isolated from chow-fed rabbits, in which fat absorption is relatively slow, transfer of apoB-48 and TAG from the SER membrane into the lumen appears to be rate limiting. In enterocytes from fat-fed rabbits, TAG accumulates into the lumen of the SER, suggesting that movement out of the SER lumen becomes rate limiting, when chylomicron secretion is markedly stimulated. In these cells, the cytosolic TAG also increased to 450 μg/g enterocytes, compared with 12 μg/g enterocytes from chow-fed rabbits, indicating that transfer of TAG from the SER membrane into the secretory pathway can become saturated, so that newly synthesized TAG moves into the cytosol.

3.150 Brain plasmin enhances APP α-cleavage and Aβ degradation and is reduced in Alzheimer's disease brains

Ledesma, M.D., Da Silva, J.S., Crassaerts, K., Delacourte, A., De Strooper, B and Dotti, C.G.
*EMBO Reports, **11(61)**, 530-535 (2000)*

The proteolytic processing of amyloid precursor protein (APP) has been linked to sphingolipid-cholesterol microdomains (rafts). However, the raft proteases that may be involved in APP cleavage have not yet been identified. In this work we present evidence that the protease plasmin is restricted to rafts of cultured hippocampal neurons. We also show that plasmin increases the processing of human APP preferentially at the α-cleavage site, and efficiently degrades secreted amyloidogenic and non-amyloidogenic APP fragments. These results suggest that brain tissue from Alzheimer's disease patients contains reduced levels of plasmin, implying that plasmin downregulation may cause amyloid plaque deposition accompanying sporadic Alzheimer's disease.

3.151 Cytosolic phospholipase A_2 regulates Golgi structure and modulates intracellular trafficking of membrane proteins

Choukroun, G.J. et al
*J. Clin. Invest, **106**, 983-993 (2000)*

The Golgi complex and the *trans*-Golgi network are critical cellular organelles involved in the endocytic and biosynthetic pathways of protein trafficking. Lipids have been implicated in the regulation of membrane protein trafficking vesicular fusion, and targeting. We have explored the role of cytosolic group IV phospholipase A_2 ($cPLA_2$) in membrane-protein trafficking in kidney epithelial cells. Adenoviral expression of $cPLA_2$ in LLC-PK_1 kidney epithelial cells prevents constitutive trafficking to the plasma membrane of an aquaporin 2-green fluorescent protein chimera, with retention of the protein in the rough endoplasmic reticulum. Plasma membrane Na^+-K^+-ATPase α-subunit localization is markedly reduced in cells expressing $cPLA_2$, whereas the trafficking of a Cl^-/ HCO_3^- anion exchanger to the plasma membrane is not altered in these cells. Expression of $cPLA_2$ results in dispersion of giantin and β-COP from their normal, condensed Golgi localization, and in marked disruption of the Golgi cisternae. $cPLA_2$ is present in Golgi fractions from noninfected LLC-PK_1 cells and rat kidney cortex. The distribution of tubulin and actin was not altered by $cPLA_2$ indicating that the microtubule and actin cytoskeleton remain intact. Total cellular protein synthesis is unaffected by the increase in $cPLA_2$ activity. Thus $cPLA_2$ plays an important role in determining Golgi architecture and selective control of constitutive membrane-protein trafficking in renal epithelial cells.

3.152 Tropism of human cytomegalovirus for endothelial cells is determined by a post-entry step dependent on efficient translocation to the nucleus
Sinzger, C. et al
J. Gen. Virol., ***81****, 3021-3035 (2000)*

Marked interstrain differences in the endothelial cell (EC) tropism of human cytomegalovirus (HCMV) isolates have been described. This study aimed to define the step during the replicative cycle of the HCMV that determines this phenotype. The infection efficiency of various HCMV strains in EC versus fibroblasts was quantified by immunodetection of immediate early (IE), early and late viral antigens. Adsorption and penetration were analyzed by radiolabeled virus binding assays and competitive HCMV-DNA-PCR. The translocation of penetrated viral DNA to the nucleus of infected cells was quantified by competitive HCMV-DNA-PCR in pure nuclear fractions. The intracytoplasmic translocation of capsids that had penetrated was followed by immunostaining of virus particles on a single particle level; this was correlated with the initiation of viral gene expression by simultaneous immunostaining of viral IE antigens. The infectivity of nonendotheliotropic HCMV strains in EC was found to be 100-1000-fold lower when compared to endotheliotropic strains. The manifestation of this phenotype at the level of IE gene expression indicated the importance of initial replication events. Surprisingly, no interstrain differences were detected during virus entry. However, dramatic interstrain differences were found regarding the nuclear translocation of penetrated viral DNA. With nonendotheliotropic strains, the content of viral DNA in the cell nucleus was 100-1000-fold lower in EC when compared to endotheliotropic strains, thereby reflecting the strain differences in IE gene expression. Simultaneous staining of viral particles and viral IE antigen revealed that interstrain differences in the transport of penetrated capsids towards the nucleus of endothelial cells determine the EC tropism of HCMV.

3.153 B cell antigen receptor signaling occurs outside lipid rafts in immature B cells
Sproul, T.W., Malapati, S., Kim, J. and Pierce, S.
J. Immunol., ***165****, 6020-6023 (2000)*

B cell Ag receptor (BCR) signaling changes dramatically during B cell development, resulting in activation in mature B cells and apoptosis, receptor editing, or anergy in immature B cells. BCR signaling in mature B cells was shown to be initiated by the translocation of the BCR into cholesterol- and sphingolipid-enriched membrane microdomains that include the Src family kinase Lyn and exclude the phosphatase CD45. Subsequently the BCR is rapidly internalized into the cell. Here we show that the BCR in the immature B cell line, WEHI-231, does not translocate into lipid rafts following cross-linking nor is the BCR rapidly internalized. The immature BCR initiates signaling from outside lipid rafts as evidenced by the immediate induction of an array of phosphoproteins and subsequent apoptosis. The failure of the BCR in immature B cells to enter lipid rafts may contribute to the dramatic differences in the outcome of signaling in mature and immature B cells.

3.154 Different properties of two isoforms of annexin XIII in MDCK cells
Lecat, S. et al
J. Cell Sci., ***113****, 2607-2618 (2000)*

Annexins form a family of proteins that are widely expressed and known to bind membranes in the presence of calcium. Two isoforms of the annexin XIII subfamily are expressed in epithelia. We previously reported that annexin XIIIb is apically localized in MDCK cells and that it is involved in raft-mediated delivery of apical proteins. We have now analyzed the properties of annexin XIIIa, which differs from annexin XIIIb by a deletion of 41 amino acids in the amino-terminal domain, and is distributed both apically and basolaterally. Annexin XIIIa binding to membranes is independent of calcium but requires its myristoyl amino-terminal modification, as observed with annexin XIIIb. Our biochemical and functional data show that annexin XIIIa behaves differently in the apical and in the basolateral compartments. Whereas annexin XIIIa apically can associate with rafts independently of calcium, the basolateral pool requires calcium for this. Annexin XIIIa, like annexin XIIIb, stimulates apical transport of influenza virus hemagglutinin but, in contrast, only annexin XIIIa inhibits basolateral transport of vesicular stomatitis virus G protein. Our results suggest that annexin XIIIa and XIIIb have specific roles in epithelial cells, and because of their structural similarities, these isoforms offer interesting tools for unravelling the functions of annexins.

3.155 New and re-emerging diseases: A dedication to Norman D. Levine
Docampo, R.
*Parasitology Today, **16(8)**, 316, (2000)*

3.156 Differential effects of acyl-CoA binding protein on enzymatic and non-enzymatic thioacylation of protein and peptide substrates
Dunphy, J.T. et al
*Biochem. Biophys. Acta, **1485**, 185-198 (2000)*

Both enzymatic and autocatalytic mechanisms have been proposed to account for protein thioacylation (commonly known as palmitoylation). Acyl-CoA binding proteins (ACBP) strongly suppress non-enzymatic thioacylation of cysteinyl-containing peptides by long-chain acyl-CoAs. At physiological concentrations of ACBP, acyl-CoAs, and membrane lipids, the rate of spontaneous acylation is expected to be too slow to contribute significantly to thioacylation of signaling proteins in mammalian cells (Leventis et al., Biochemistry 36 (1997) 5546-5553). Here we characterized the effects of ACBP on enzymatic thioacylation. A protein S-acyltransferase activity previously characterized using G-protein α-subunits as a substrate (Dunphy et al., J. Biol. Chem., 271 (1996) 7154-7159), was capable of thioacylating short lipid-modified cysteinyl-containing peptides.The minimum requirements for substrate recognition were a free cysteins thiol adjacent to a hydrophobic lipid anchor, either myristate or farnesyl isoprenoid. PAT activity displayed specificity for the acyl donor, efficiently utilizing long-chain acyl-CoAs, but not free fatty acid or S-palmitoyl-*N*-acetylcysteamine. ACBP only modestly inhibited enzymatic thioacylation of a myristoylated peptide or G-protein α-subunits under conditions where non-enzymatic thioacylation was reduced to background. Thus, protein S-acyltransferase remains active in the presence of physiological concentrations of ACBP and acyl CoA in vitro and is likely to represent the predominant mechanism of thioacylation in vivo.

3.157 Cytosolic Hsp70s are involved in the transport of aminopeptidase 1 from the cytoplasm into the vacuole
Satyanarayana, C., Schroder-Kohne, S., Craig, E.A., Schu, P.V. and Horst, M.
*FEBS Lett., **470**, 232-238 (2000)*

Eukaryotic 70 kDa heat shock proteins (Hsp70s) are localized in various cellular compartments and exhibit functions such as protein translocation across membranes, protein folding and assembly. Here we demonstrate that the constitutively expressed members of the yeast cytoplasmic Ssa subfamily, Ssa1/2p, are involved in the transport of the vacuolar hydrolase aminopeptidase 1 from the cytoplasm into the vacuole. The Ssap family members displayed overlapping functions in the transport of aminopeptidase 1. In *SSAI* and *SSAII* deletion mutants the precursor of aminopeptidase 1 accumulated in a dodecameric complex that is packaged in prevacuolar transport vesicles. Ssa1/2p was prominently localized to the vacuolar membrane, consistent with the role we propose for Ssa proteins in the fusion of transport vesicles with the vacuolar membrane.

3.158 Seasonal variation in mussel *Mytilus edulis* digestive gland cytochrome P4501A- and 2E-immunoidentified protein levels and DNA strand breaks (Comet assay)
Shaw, J.P., Large, A.T., Chipman, J.K., Livingstone, D.R. and Peters, L.D.
*Marine Environmental Res., **50**, 405-409 (2000)*

Mytilus edulis digestive gland microsomes were prepared from indigenous populations sampled from a clean reference site (Pot Quin) and an urban-industrial contaminated site (Blackpool) in the UK. Samples were collected in March/April, May, August and December 1998. Western blot analysis was performed using polyclonal antibodies to fish CYP1A and rat CYP2E using partially purified *M. edulis* CYP as a positive control, to aid identification. CYP1A- and CYP2E-immunopositive protein levels showed different site-specific seasonal variation with higher levels of CYP2E determined in May ($P< 0.05$). At both sites, lower levels of CYP1A-immunopositive protein but not CYP2E-immunopositive protein were observed in the samples collected in December ($P < 0.05$). This correlated with lower levels of nuclear DNA damage (Comet assay expressed as per cent tail DNA) observed in December compared to August ($P < 0.05$).

3.159 Tyrosine mutants are capable of prodrug activation in transfected nonmelanotic cells
Simonova, M., Wall, A., Weissleder, R. and Bogdanov, A.
*Cancer Res., **60**, 6656-6662 (2000)*

Tyrosinase has been suggested as a prodrug-converting enzyme for the treatment of melanoma. We hypothesized that tyrosinase expression in transfected nonmelanotic cells can be used in a gene therapy paradigm of prodrug activation. To verify our hypothesis, we used the following tyrosinase variants: (a) a full-length human tyrosinase clone (T); (b) a mutant lacking the COOH-terminal cytoplasmic domain (TΔC); (c) a mutant lacking the COOH-terminal transmembrane and cytoplasmic domains (TΔTC); and (d) a fusion with the eight COOH-terminal amino acids of lysosome-associated membrane protein-1 (TL). Expression of mutant and wild-type tyrosinases was induced by transfection in nontumorigenic human cells of epithelial origin (293HEK, MCF-10A adenoma, and NHDF-Ad human dermal fibroblasts) as well as in tumour cells (9L gliocarcinoma, MCF7 adenocarcinoma and HT-1080 fibrosarcoma). When compared with the wild-type tyrosinase transfectants, truncated mutant expression resulted in higher mRNA levels that paralleled higher enzyme activity of the truncated mutants. Two model tyrosinase prodrugs, hydroxyphenyl-propanol (HPP) and N-acetyl-4-S-cysteaminylphenol (NAcSCAP) inhibited proliferation and caused cell death of transfected cells in a dose-dependent manner. Effects of prodrug treatment were compared for tumorigenic cells and their nontumorigenic counterparts. Two truncated mutants (TΔC and TΔTC) showed low endogenous cytotoxicity and efficiently suppressed proliferation and induced cytotoxicity in transfected tumor cells in the presence of NAcSCAP. Overall, these results indicate that the developed tyrosinase mutants hold promise as prodrug activation systems for tumoral gene therapy.

3.160 GFRα –mediated localization of RET to lipid rafts is required for effective downstream signaling, differentiation, and neuronal survival
Tansey, M.G., Baloh, R.H., Milbrandt, J. and Johnson, Jr., E.M.
*Neuron, **25**, 611-623 (2000)*

The GDNF family ligands (GFLs: GDNF, neurturin, persephin, and artemin) signal through RET and a glycosyl-phosphatidylinositol (GPI)-anchored coreceptor (GFRα1-α4) that binds ligand with high affinity and provides specificity. The importance of the GPI anchor is not fully understood; however, GPI-linked proteins cluster into lipid rafts, structures that may represent highly specialized signaling organelles. Here, we report that GPI-anchored GFRα 1 recruits RET to lipid rafts after GDNF stimulation and results in RET/Src association. Disruption of RET localization using either transmembrane-anchored or soluble GFRα1 results in RET phosphorylation, but GDNF-induced intracellular signaling events are markedly attenuated as are neuronal differentiation and survival responses. Therefore, proper membrane localization of RET via interaction with a raft-localized, GPI-linked coreceptor is of fundamental importance in GFL signaling.

3.161 Amyloid precursor proteins inhibit heme oxygenase activity and augment neurotoxicity in Alzheimer's disease
Takahashi, M. et al
*Neuron, **28**, 461-473 (2000)*

Amyloid precursor protein (APP) generates the β-amyloid peptide, postulated to participate in the neurotoxicity of Alzheimer's disease. We report that APP and APLP bind to heme oxygenase (HO), an enzyme whose product, bilirubin, is antioxidant and neuroprotective. The binding of APP inhibits HO activity, and APP with mutations linked to the familial Alzheimer's disease (FAD) provides substantially greater inhibition of HO activity than wild-type APP. Cortical cultures from transgenic mice expressing Swedish mutant APP have greatly reduced bilirubin levels, establishing that mutant APP inhibits HO activity in vivo. Oxidative neurotoxicity is markedly greater in cerebral cortical cultures from APP Swedish mutant transgenic mice than wild-type cultures. These findings indicate that augmented neurotoxicity caused by APP-HO interactions may contribute to neuronal cell death in Alzheimer's disease.

3.162 Mutational and biochemical analysis of plasma membrane targeting mediated by the farnesylated, polybasic carboxy terminus of K-ras4B

Roy, M-O., Leventis, R. and Silvius, J.R.

*Biochemistry, **39**, 8298-8307 (2000)*

Mutational analysis and in vitro assays of membrane association have been combined to investigate the mechanism of plasma membrane targeting mediated by the farnesylated, polybasic carboxy-terminal sequence of K-ras4B in mammalian cells. Fluorescence-microscopic localization of chimeric proteins linking the enhanced green fluorescent protein (EGFP) to the K-ras4B carboxy-terminal sequence, or to variant forms of this sequence, reveals that the normal structure of this targeting motif can be greatly altered without compromising plasma membrane-targeting activity so long as an overall strongly polybasic/amphiphilic character is retained. An EGFP/K-ras4B(171-188) chimeric protein was readily abstracted from isolated cell membranes by negatively charged lipid vesicles, and this abstraction was markedly enhanced by the anionic lipid-binding agent neomycin. Our results strongly favor a mechanism in which at the plasma membrane the carboxy-terminal sequence of K-ras4B associates not with a classical specific proteinaceous receptor but rather with nonspecific but highly anionic 'sites' formed at least in part by the membrane lipid bilayer. Our findings also suggest that the recently demonstrated prenylation-dependent trafficking of immature forms of K-ras4B through the endoplasmic reticulum [Choy et al. (1999) Cell 98, 69-80], while required for maturation of the protein, beyond this stage may not be essential to allow the ultimate delivery of the mature protein to the plasma membrane.

3.163 An ever-expanding story of cyst formation

Gallagher, A.R., Obermüller, N., Cedzich, A., Gretz, N. and Witzgall, R.

*Cell Tissue Res., **300**, 361-371 (2000)*

Autosomal-dominant polycystic kidney disease represents one of the most common monogenetic human disorders. The cloning of the *PKD1* and *PKD2* genes, which are mutated in far more than 90% of the patients affected by this disease, has generated high hopes for a quick understanding of the pathogenesis of cyst formation. However, these expectations have not yet been fulfilled, since the function of both polycystin-1 and polycystin-2, the two proteins encoded by *PKD1* and *PKD2*, still remains a puzzle. In this review, we will highlight some of the characteristics of polycystic kidney disease, briefly touch on polycystin-1, and then go on to describe recent results of experiments with polycystin-2, since the latter is the major focus of our work. We will discuss new evidence which suggests that autosomal-dominant polycystic kidney disease actually behaves recessively on a cellular level. Finally, a model will be presented that tries to explain the available data.

3.164 Ultrastructural characterization of the delimiting membranes of isolated autophagosomes and amphisomes by freeze-fracture electron microscopy

Fengsrud, M., Erichsen, E.S., Berg, T.O., Raiborg, C. And Seglen, P.O.

*Eur. J. Cell Biol., **79**, 871-882 (2000)*

The delimiting membranes of isolated autophagosomes from rat liver had extremely few transmembrane proteins, as indicated by the paucity of intramembrane particles in freeze-fracture images (about 20 particles/um^2, whereas isolated lysosomes had about 2000 particles/um^2). The autophagosomes also appeared to lack peripheral surface membrane proteins, since attempts to surface-biotinylate intact autophagosomes only yielded biotinylation of proteins from contaminating damaged mitochondria. All the membrane layers of multilamellar autophagosomes were equally particle-poor; the same was true of the autophagosome-forming, sequestering membrane complexes (phagophores). Isolated amphisomes (vacuoles formed by fusion between autophagosomes and endosomes) had more intramembrane particles than the autophagosomes (about 90 particles/um^2), and freeze-fracture images of these organelles frequently showed particle-rich endosomes fusing with particle-poor or particle-free autophagosomes. The appearance of multiple particle clusters suggested that a single autophagic vacuole could undergo multiple fusions with endosomes. Only the outermost membrane of bi-or multilammelar autophagic vacuoles appeared to engage in such fusions.

3.165 The phagacytosis-associated respiratory burst in human monocytes is associated with increased uptake of glutathione

Seres, T., Knickelbein, R.G., Warshaw, J.B. and Johnston, Jr, R.B.
J. Immunol., ***165****, 3333-3340 (2000)*

During the phagocytic respiratory burst, oxygen is converted to potent cytotoxic oxidants. Monocytes and macrophages are potentially long-lived, and we have hypothesized that protective mechanisms against oxidant stress are varied and fully expressed in these cells. We report here that the respiratory burst in monocytes is accompanied by an increase in the uptake of [^{35}S]glutathione ([^{35}S]GSH) after 20–30 min to levels up to 10-fold greater than those at baseline. By 30 min, 49% of the cell-associated radioactivity was in the cytosol, 41% was in membrane, and 10% was associated with the nuclear fraction. GSH uptake was inhibited by catalase, which removes hydrogen peroxide (H_2O_2), and micromolar H_2O_2 stimulated GSH uptake effectively in monocytes and also lymphocytes. Oxidation of GSH to glutathione disulfide with H_2O_2 and glutathione peroxidase prevented uptake. Acivicin, which inhibits GSH breakdown by γ-glutamyl transpeptidase (GGT), had no effect on the enhanced uptake seen during the respiratory burst. Uptake of cysteine or cystine, possible products of GGT activity, stayed the same or decreased during the respiratory burst. These results suggest that a GGT-independent mechanism is responsible for the enhanced GSH uptake seen during the respiratory burst. We describe here a sodium-independent, methionine-inhibitable transport system with a K_m (8.5 μM) for GSH approximating the plasma GSH concentration. These results suggest that monocytes have a specific GSH transporter that is triggered by the release of H_2O_2 during the respiratory burst and that induces the uptake of GSH into the cell. Such a mechanism has the potential to protect the phagocyte against oxidant damage.

3.166 Expression and localization of rab escort protein isoforms in parotid acinar cells from rat

Chan, D., Lin, J. and Raffaniello, R.D.
J. Cell. Physiol., ***185(3)****, 339-347 (2000)*

Rab proteins are geranylgeranylated on their carboxyl terminal cysteine motifs by geranylgeranyltransferase II (GGTase). Rab escort protein (REP) is required to present Rab proteins to GGTase. REP may remain bound to newly isoprenylated Rab proteins and present them to their target membrane. Other studies have shown that Rab proteins cycle between the membrane and cytosolic compartments and that cytosolic Rab proteins are complexed with rab-GDI. In the present study, we examined the expression and localization of REP isoforms in parotid acinar cells. Although both REP isoforms, REP-1 and REP-2, were detected in parotid cytosol, REP-2 was the predominant isoform. Subcellular fractionation revealed that approximately 42% of cellular REP-2 is membrane-associated. REP-2 was partially removed from parotid membranes with 1 M NaCl or Na2CO3, indicating that REP-2 is a peripheral membrane protein. Membrane-associated REP-2 did not colocalize with Rab3D on secretory granule membranes. However, density gradient centrifugation revealed that membrane-associated REP-2 and Rab3D colocalize on low- and high-density membrane fractions in parotid acinar cells. Isoproterenol, an agent which induces amylase release from parotid glands, caused a shift in both REP-2 and Rab3D to less dense membrane fractions. When acinar cell cytosol was fractionated by gel filtration chromatography, Rab3D eluted exclusively with REP, not rab-GDI. In contrast, Rab1B and Rab5 eluted with both REP and Rab-GDI. Colocalization of Rab3D and REP-2 on acinar cell membranes suggests that REP-2 plays a role in delivering Rab3D to parotid membranes and may regulate guanine nucleotide binding to membrane-associated Rab3D. In addition, unlike other Rab proteins, cytosolic Rab3D appears to associate exclusively with REP, not rab-GDI in parotid acinar cells.

3.167 Mutation of conserved aspartates affect maturation of presenilin 1 and presenilin 2 complexes

Yu, G., Chen, F., Nishimura, M., Steiner, H., Tandon, A., Kawarai, T., Arawaka, S., Supala, A., Song, Y-Q., Rogaeva, E., Holmes, E., Zhang, D.M., Milman, P., Fraser, P., Haass, C. and St. George-Hyslop, P.
Acta Neurol Scand., ***Suppl. 176****, 6-11 (2000)*

Presenilin (PS1 and PS2) holoproteins are transiently incorporated into low molecular weight (MW) complexes. During subsequent incorporation into a higher MW complex, they undergo endoproteolysis to generate stable N- and C-terminal fragments (NTF/CTF). Mutation of either of two conserved aspartate residues in transmembrane domains inhibits both presenilin-endoproteolysis and the proteolytic processing of APP and Notch. We show that aspartate-mutant holoprotein presenilins are not incorporated into the high molecular weight, NTF/CTF-containing complexes. Aspartate-mutant presenilin holoproteins also preclude entry of endogenous wild-type PS1/PS2 into the high molecular weight complexes, but do not affect the incorporation of wild-type holoproteins into lower molecular weight holoprotein complexes.

These data suggest that the loss-of-function aspartate-mutants cause altered PS complex maturation, and argue that the functional presenilin moieties are contained in the high molecular weight presenilin NTF/CTF-containing complexes.

3.168 Degradation of lipid vesicles in the yeast vacuole requires function of Cvt17, a putative lipase
Teter, S.A. et al
J. Biol. Chem., ***276(1)***, *2083-2087 (2001)*

The vacuole/lysosome serves an essential role in allowing cellular components to be degraded and recycled under starvation conditions. Vacuolar hydrolases are key proteins in this process. In *Saccharomyces cerevisiae*, some resident vacuolar hydrolases are delivered by the cytoplasm to vacuole targeting (Cvt) pathway, which shares mechanistic features with autophagy. Autophagy is a degradative pathway that is used to degrade and recycle cellular components under starvation conditions. Both the Cvt pathway and autophagy employ double-membrane cytosolic vesicles to deliver cargo to the vacuole. As a result, these pathways share a common terminal step, degradation of subvacuolar vesicles. We have identified a protein, Cvt17, which is essential for this membrane lytic event. Cvt17 is a membrane glycoprotein that contains a motif conserved in esterases and lipases. The active-site serine of this motif is required for sub-vacuolar vesicle lysis. This is the first characterization of a putative lipase implicated in vacuolar function in yeast.

3.169 An ephrinA-dependent signaling pathway controls integrin function and is linked to the tyrosine phosphorylation of a 120 kDa protein
Huai, J.and Drescher, U.
J. Biol. Chem., ***276(9)***, *6689-6694 (2001)*

The Eph family of receptor tyrosine kinases and their ligands, the ephrins, have been implicated in the development of the retinotectal projection. Here, glycosylphoaphatidylinositol-anchored A-ephrins are not only expressed in the tectum, but also on retinal axons, raising the possibility that they function in this context as receptors. We now show that activation of ephrinA2 or ephrinA5 by one of their receptors, ephA3, results in a β1-integrin dependent increased adhesion of ephrinA-expressing cells to laminin. In the search for an ephrinA-dependent signaling pathway controlling integrin activation, we identified a 120 kDa raft membrane protein which is tyrosine phosphorylated specifically after ephrinA activation. Tyrosine phosphorylation of this protein is not seen after stimulating ephrinA2-expressing cells with basic fibroblast growth factor, epidermal growth factor, insulin growth factor or fetal calf serum containing a large set of different growth factors. The role of p120 as a mediator of an ephrinA - integrin coupling is supported by the finding that inhibiting tyrosine phosphorylation of pl20 correlates with an abolishment of the β1-dependent cell adhesion.

3.170 The synaptic vesicle protein, cysteine-string, is associated with the plasma membrane in 3T3-L1 adipocytes and interacts with syntaxin 4
Chamberlain, L.H. et al
J. Cell Sci., ***114(2)***, *445-455 (2001)*

Adipocytes and muscle cells play a major role in blood glucose homeostasis. This is dependent upon the expression of Glut4, an insulin-responsive facilitative glucose transporter. Glut4 is localized to specialized intracellular vesicles that fuse with the plasma membrane in response to insulin stimulation. The insulin-induced translocation of Glut4 to the cell surface is essential for the maintenance of optimal blood glucose levels, and defects in this system are associated with insulin resistance and type II diabetes. Therefore, a major focus of recent research has been to identify and characterize proteins that regulate Glut4 translocation. Cysteine-string protein (Csp) is a secretory vesicle protein that functions in presynaptic neurotransmission and also in regulated exocytosis from non-neuronal cells. We show that Csp1 is expressed in 3T3-L1 adipocytes and that cellular levels of this protein are increased following cell differentiation. Combined fractionation and immunofluorescence analyses reveal that Csp1 is not a component of intracellular Glut4-storage vesicles (GSVs), but is associated with the adipocytes plasma membrane. This association is stable, and not affected by either insulin stimulation or chemical depalmitoylation of Csp1. We also demonstrate that Csp1 interacts with the t-SNARE syntaxin 4. As syntaxin 4 is an important mediator of insulin-stimulated GSV fusion with the plasma membrane, this suggests that Csp1 may play a regulatory role in this process. Syntaxin 4 interacts specifically with Csp1, but not with Csp2. In contrast, syntaxin 1A binds to both Csp isoforms, and actually exhibits a higher affinity for the Csp2 protein.

The results described raise a number of interesting questions concerning the intracellular targeting of Csp in different cell types, and suggest that the composition and synthesis of GSVs may be different from synaptic and other secretory vesicles. In addition, the interaction of Cps1 with syntaxin 4 suggests that this Csp isoform may play a role in insulin-stimulated fusion of GSVs with plasma membrane.

3.171 Pro-caspase-8 is pre-dominantly localized in mitochondria and released into cytoplasm upon apoptotic stimulation
Qin, Z-H. et al
J. Biol. Chem., ***276(11)****, 8079-8086 (2001)*

The recruitment and cleavage of pro-caspase-8 to produce the active form of caspase-8 is a critical biochemical event in death receptor-mediated apoptosis. However, the source of pro-caspase-8 available for activation by apoptotic triggers is unknown. In human fibroblasts and mouse clonal striatal cells, confocal microscopy revealed that pro-caspase-8 immunofluorescence was co-localized with cytochrome c in mitochondria and was also distributed diffusely in some nuclei. Biochemical analysis of subcellular fractions indicated that pro-caspase-8 was enriched in mitochondria and in the nucleus. Pro-caspase-8 was found in the intermembrane space, inner membrane and matrix of mitochondria after limited digestion of mitochondrial fractions and this distribution was confirmed by immunogold electron microscopy. Pro-caspase-8 and cytochrome c were released from isolated mitochondria that were treated with an inhibitor of the ADP/ATP carrier atractyloside (Atr), which opens the mitochondrial permeability transition pore. Release was blocked by the mitochondrial permeability transition pore inhibitor cyclosporin A (CsA). After clonal striatal cells were exposed for 6 hr to the apoptotic inducer, tumor necrosis factor-α (TNF-α), mitochondria immunoreactive for cytochrome c and pro-caspase-8 became clustered at perinuclear sites. Pro-caspase-8 and cytochrome c levels decreased in mitochondrial fractions and increased, along with pro-caspase-8a cleavage products, in the cytoplasm of the TNF-alpha treated striatal cells. CsA blocked the TNF-α-induced release of pro-caspase 8, but not cytochrome c. Internucleosomal DNA fragmentation started at 6 hr and peaked at 12 hr after TNF-α treatment. These results suggest that pro-caaspase-8 is predominately localized in mitochondria and is released upon apoptotic stimulation through a CsA-sensitive mechanism.

3.172 Hrs interacts with sorting nexin 1 and regulates degradation of epidermal growth factor receptor
Chin, L-S., Raynor, M.C., Wei, X., Chen, H-Q. and Li, L.
J. Biol. Chem., ***276(10)****, 7069-7078 (2001)*

Hepatocyte growth factor-regulated tyrosine kinase substrate (Hrs) is a mammalian homologue of yeast vacuolar protein sorting (Vps) protein Vps27p, however the role of Hrs in lysosomal trafficking is unclear. Here, we report that Hrs interacts with sorting nexin 1 (SNX1), a recently identified mammalian homologue of yeast Vps5p that recognize the lysosomal targeting code of epidermal growth factor receptor (EGFR) and participates in lysosomal trafficking of the receptor. Biochemical analyses demonstrate that Hrs and SNX1 are ubiquitous proteins that exist in both cytosolic and membrane-associated pools, and that the association of Hrs and SNX occurs on cellular membranes but not in the cytosol. Furthermore, endogenous SNX1 and Hrs form a ~550-kDa complex that excludes EGFR. Immunofluorescence and subcellular fractionation studies show that Hrs and SNX1 colocalize on early endosomes. By using depletion analysis, we have mapped the binding domains of Hrs and SNX1 that mediate their association. Overexpression of Hrs or its SNX1-binding domain inhibits ligand-induced degradation of EGFR, but does not affect either constitutive or ligand-induced receptor-mediated endocytosis. These results suggest that Hrs may regulate lysosomal trafficking through its interaction with SNX1.

3.173 Localization and insulin-regulated relocation of phosphoinositide 5-kinase PIKfyve in 3T3-L1 adipocytes
Shisheva, A., Rusin, B., Ikonomov, O.C., DeMarco, C. and Sbrissa, D.
J. Biol. Chem., ***276(15)****, 11859-11869 (2001)*

The mammalian phosphoinositide kinase PIKfyve catalyzes the synthesis of phosphatidylinositol 5-P and phosphatidylinositol 3,5-P_2, thought essential in cellular functions, including membrane trafficking. To discern the intracellular loci of PIKfyve product's formation, we have examined the localization of PIKfyve protein vs. enzymatic activity, and a possible acutely regulated redistribution in 3T3-L1 adipocytes. Subcellular fractions of resting cells that were positive for immunoreactive PIKfyve, such as cytosol (~76%), internal structures (LDM, composed of recycling endosomes, GLUT4 storage compartment, Golgi and cytoskeletal elements) (~20%), and plasma membrane (~4%), expressed

enzymatically active PIKfyve. While presence of FYVE finger in PIKfyve predicts early endosome targeting, density gradient sedimentation, immunoadsorption and fluorescence microscopy analyses segregated the LDM-associated PIKfyve from the membranes of the recycling endosomes and GLUT4. PIKfyve fluorescence staining largely coincided with trans-Golgi network/multivesicular body markers, indicating PIKfyve's role in the late endocytic/biosynthetic pathways. A subfraction of particulate PIKfyve resisted nonionic detergent treatment, implying association with cytoskeletal structures, previously found positive for key members of the insulin signaling cascade. Upon acute stimulation of 3T3-L1 adipocytes with insulin or pervanadate, a portion of the cytosolic PIKfyve was recruited onto LDM, which was coupled with a commensurate increase of PIKfyve lipid kinase activity and an electrophoretic mobility shift. We suggest the recruited PIKfyve specifies the site and timing of phosphoinositide signals that are relevant to the acute insulin action.

3.174 Active (9.6S) and inactive (21S) oligomers of NHE3 in distinct microdomains of the renal brush border

Biemesderfer, D., DeGray, B. and Aronson, P.S.
J. Biol. Chem., ***276(13)***, *10161-10167* ***(****2001)*

We have previously shown that Na^+-H^+ exchanger isoform NHE3 exists as both 9.6 S and 21 S (megalin-associated) oligomers in the renal brush border (Biesmesderfer et al., JBC 274, 17518, 1999). To characterize the oligomeric forms of the renal brush border Na^+-H^+ exchanger in more detail, we performed membrane fractionation studies. We found that similar amounts of NHE3 were present in microvilli and a non-microvillar membrane domain of high density (dense vesicles). Horseradish peroxidase-labeled endosomes were not prevalent in the dense membrane fraction. However, megalin, which localizes primarily to the intermicrovillar microdomain of the brush border, was enriched in the dense vesicles, implicating this microdomain as the likely source of these membranes. Immunolocalization of NHE3 confirmed that a major fraction of the transporter co-localized with megalin in the intermicrovillar region of the brush border. Immunoprecipitation studies demonstrated that in microvilli the majority of NHE3 was not bound to megalin, while in the dense vesicles most of the NHE3 co-precipitated with megalin. Moreover, sucrose velocity gradient centrifugation experiments revealed that most NHE3 in microvilli sedimented with an S-value of 9.6 while the S-value of NHE3 in dense vesicles was 21. Finally, we examined the functional state of NHE3 in both membrane fractions. As assayed by changes in acridine orange fluorescence, imposing an outwardly directed Na^+ gradient caused generation of an inside-acid pH gradient in the microvilli, indicating Na^+-H^+ exchange activity, but not in the dense vesicles. Taken together, these data demonstrate that renal brush border NHE3 exists in two oligomeric states; a 9.6 S active form present in microvilli, and a 21 S, megalin-associated, inactive form in the intermicrovillar microdomain of the apical plasma membrane. Thus, regulation of renal brush border Na^+-H^+ exchange activity may be mediated by shifting the distribution between these forms of NHE3.

3.175 Membrane lipid rafts are necessary for the maintenance of the α7 nicotinic acetylcholine receptor in somatic spines of ciliary neurons

Bruses, J.L., Chauvet, N. and Rutishauser, U.
J. Neurosci., ***21(2)***, *504-512 (2001)*

Calcium-permeable neurotransmitter receptors are concentrated into structurally and biochemically isolated cellular compartments to localize calcium-mediated events during neurotransmission. The cytoplasmic membrane contains lipid microdomains called lipid rafts, which can gather into microscopically visible clusters, and thus the association of a particular protein with lipid rafts can result in its redistribution on the cell surface. The present study asks whether lipid rafts participate in the formation and maintenance of the calcium-permeable α7-subunit nicotinic acetylcholine receptor (α7nAChR) clusters found in somatic spines of ciliary neurons. Lipid rafts and α7nAChR become progressively colocalized within somatic spines during synaptogenesis. To determine whether these rafts are required for the maintenance of a7nAChR aggregates, cholesterol was extracted from dissociated ciliary neurons by treatment with methyl-β-cyclodextrin. This treatment caused the dispersion of lipid rafts and the redistribution of α7nAChR into small clusters over the cell surface, suggesting that the integrity of lipid rafts is required to maintain the receptor clustering. However, lipid raft dispersion also caused the depolymerization of the F-actin cytoskeleton, which can also tether the receptor at specific sites. To assess whether interaction between rafts and α7nAChR is independent of F-actin filaments, the lipid raft patches were stabilized with a combination of the cholera toxin B subunit (CTX), which specifically binds to the raft component ganglioside GM1, and an antibody against CTX. The stabilized rafts were then treated with latrunculin-A to depolymerize F-actin. Under these conditions, large patches of CTX persisted and

were colocalized with a7nAChR, indicating that the aggregates of receptors can be maintained independently of the underlying F-actin cytoskeleton. Moreover, it was found that the a7nAChR is resistant to detergent extraction at 4^0C and floats with the caveolin-containing lipid-rich fraction during density gradient centrifugation, properties that are consistent with a direct association between the receptor and the membrane microdomains.

3.176 Mutations in sialidosis impair sialidase binding to the lysosomal multienzyme complex
Lukong, K.E. et al
*J. Biol. Chem., **276,** 17286-17290 (2001)*

Sialidosis is an autosomal recessive disease caused by the genetic deficiency of lysosomal sialidase, which catalyzes the catabolism of sialoglycoconjugates. The disease is associated with progressive impaired vision, macular cherry-red spots, and myoclonus (sialidosis type 1) or with skeletal dysplasia, Hurler-like phenotype, dysostosis multiplex, mental retardation, and hepatosplenomegaly (sialidosis type II). We have analyzed the effect of missense mutations, G68V, Sl82G, G227R, F26OY, L270F, A298V, G328S and L363P, identified in the sialidosis type I and sialidosis type II patients on the activity, stability and intracellular distribution of the sialidase. We found that 3 mutations, F260Y, L270F and A298V which are clustered in the same region on the surface of sialidase molecule dramatically reduce the enzyme activity and cause a rapid intralysosomal degradation of the expressed protein. We suggested that this region might be involved in the sialidase binding with lysosomal cathepsin A and/or β-galactosidase in the multienzyme lysosomal complex required for the expression of sialidase activity. Transgenic expression of mutants followed by density gradient centrifugation of cellular extracts confirmed this hypothesis and showed that sialidase deficiency in some sialidosis patients results from disruption of the lysosomal multienzyme complex.

3.177 Mammalian sprouty-1 and –2 are membrane-anchored phosphoprotein inhibitors of growth factor signaling in endothelial cells

Impagnatiello, M-A. et al

*J. Cell Biol., **152(5)**, 1087-1098 (2001)*

Growth factor-induced signaling by receptor tyrosine-kinases (RTKs) plays a central role in embryonic development and in pathogenesis and, hence, is tightly controlled by several regulatory proteins. Recently, Sprouty, an inhibitor of *Drosophila* development-associated RTK signaling, has been discovered. Subsequently, four mammalian Sprouty homologues (Spry 1-4) have been identified. Here, we report for functional characterization of two of them, Spry-1 and –2, in endothelial cells. Overexpressed Spry-1 and -2 inhibit fibroblast growth factor- and vascular endothelial growth factor-induced proliferation and differentiation by repressing pathways leading to p42/44 mitogen activating protein (MAP) kinase activation. In contrast, although epidermal growth factor-induced proliferation of endothelial cells were also inhibited by Spry-1 and –2, activation of p42/44 MAP kinase was not affected. Biochemical and immunofluorescence analysis of endogenous and overexpressed Spry-1 and –2 reveal that both Spry-1 and –2 are anchored to membranes by palmitoylation and associate with caveolin-1 in perinuclear and vesicular structures. They are phosphorylated on serine residues and, upon growth factor stimulation, a subset is recruited to the leading edge of the plasma membrane. The data indicate that mammalian Spry-1 and -2 are membrane-anchored proteins that negatively regulate angiogenesis-associated RTK signaling, possibly in an RTK-specific fashion.

3.178 Cytosolic phospholipase A_2-α associates with plasma membrane, endoplasmic reticulum and nuclear membrane in glomerular epithelial cells

Liu, J., Takano, T., Papillon, J., Khadir, A. and Cybulsky, A.V.

*Biochem. J., **353**, 79-90 (2001)*

Eicosanoids mediate complement-dependent glolmerular epithelial injury in experimental membranous nephropathy. The release of arachidonic acid from phospholipids by cytosolic phospholipase A_2 ($cPLA_2$) is the rate-limiting step in eicosanoid synthesis. The present study examines the association of $cPLA_2$ with membranes of organelles. Glomerular epithelial cells were disrupted by homogenization in Ca^{2+} -free buffer; organelles were separated by gradient centrifugation. The distribution of $cPLA_2$, and organelles was analyzed by immunoblotting with antibodies against $cPLA_2$ and organelle markers, or by enzyme assay. In cells incubated with or without the Ca^{2+} ionophore ionomycin plus PMA, $cPLA_2$ co-localized with plasma membrane, endoplasmic reticulum and nuclei, but not with mitochondria or Golgi. A greater amount of $cPLA_2$ was associated with membranes in stimulated cells, but membrane-associated $cPLA_2$ was readily detectable under resting conditions. The pattern of association of $cPLA_2$ with membrane in cells treated with antibody and complement was similar to that in cells stimulated with ionomycin plus PMA; however, complement did not enhance the membrane association of $cPLA_2$ protein. To determine the functional role of membrane association of $cPLA_2$, phospholipids were labeled with [^{3}H]arachidonic acid. Cells were then incubated with or without antibody and complement and were fractionated. Complement induced a loss of radioactivity from the plasma membrane, endoplasmic reticulum and nuclei, but not from the mitochondrial fraction. Thus the release of arachidonic acid by $cPLA_2$ is due to the hydrolysis of phospholipids at multiple subcellular membrane sites, including the endoplasmic reticulum, plasma membrane and nucleus.

3.179 Raft-partitioning of the ubiquitin ligases CbI and Nedd4 upon IgE-triggered cell signaling
Lafont, F. and Simons, K.
*Proc. Natl. Acad. Sci., USA., **98**; 3180-3184 (2001).*

The high affinity receptor for IgE, FcεRI on mast calls and basophils plays an essential role in immunological defense. Upon multivalent antigen binding, FcεRI becomes phoshorylated by the protein--tyrosine kinase Lyn, as a result of receptor clustering in lipid rafts. FcεRI has been shown to be ubiquitinated. Ubiquitination can lead to degradation by proteasomes, but it can also act as a sorting signal to internalize proteins destined to the endosomal/lysosomal pathway. We have analyzed whether FcεRI ubiquitination takes place within rafts. We report biochemical and imaging evidence in rat basolukemia cells for the presence of ubiquitinated FcεRI in clustered rafts upon receptor activation. Moreover, we demonstrated that the ubiquitin ligases CbI and Nedd4 co-localize with FcεRI patches and showed that both ligases become assoc-iated with lipid rafts after activation of IgE signaling. Because CbI is known to interact with the FcεRI signaling complex, ubiquitination is likely to be an important parameter regulating IgE-triggered signaling occurring in rafts.

3.180 Cell-specific targeting of caveolin-1 to caveolae, secretory vesicles, cytoplasm or mitochondria
Li, W-P et al
*J. Cell Sci., **114(7)**, 1397-1408 (2001)*

In commonly used tissue culture cells, caveolin-1 is embedded in caveolae membranes. It appears to reach this location after being cotranslationally inserted into ER membranes, processed in the Golgi and shipped to the cell surface. We now report that caveolae are not the preferred location for caveolin-1 in all cell types. Skeletal muscle cells and keratinocytes target caveolin-1 to the cytosol while in exocrine and endocrine cells it accumulates in the secretory pathway. We also found that airway epithelial cells accumulate cevaolin-1 in modified mitochondria. The cytosolic and the secreted forms appear to be incorporated into a soluble, lipid complex. We conclude that caveolin-1 can be targeted to a variety of intracellular destinations, which suggests a novel mechanism for the intracellular traffic of this protein.

3.181 Glycolipid antigen processing for presentation by CD1d molecules
Prigozy, T.I. et al
*Science, **291**, 664-667 (2001)*

The requirement for processing glycolipid antigens in T cell recognition was examined with mouse CD1d-mediated responses to glycosphingolipids (GSLs). Although some disaccharide GSL antigens can be recognized without processing, the responses to three other antigens, including the disaccharide GSL Gal(α1$\rightarrow$2)GalCer (Gal, galactose; GalCer, galactosylceramide), required removal of the terminal sugars to permit interaction with the T cell receptor. A lysosomal enzyme, α-galactosidase A, was responsible for the processing of Gal(α1$\rightarrow$2)GalCer to generate the antigenic monosaccharide epitope. These data demonstrate a carbohydrate antigen processing system analogous to that used for peptides and an ability of T cells to recognize processed fragments of complex glycolipids.

3.182 Segregation of heterotrimeric G proteins in cell surface microdomains
Oh, P. and Schnitzer, J.E.
*Mol. Biol. Cell, **12**, 685-698 (2001)*

Select lipid-anchored proteins such as glycosylphosphatidylinositol (GPI)-anchored proteins and nonreceptor tyrosine kinase may preferentially partition into sphingomyelin-rich and cholesterol-rich plasmalemmal microdomains, thereby acquiring resistance to detergent extraction. Two such domains, caveolae and lipid rafts, are morphologically and biochemically distinct, contain many signaling molecules, and may function in compartmentalizing cell surface signaling. Subfractionation and confocal immunofluorescence microscopy reveal that, in lung tissue and in cultured endothelial and epithelial cells, heterotrimeric G proteins (G_i, G_q, G_s, and $G_{\beta\gamma}$) target discrete cell surface microdomains. G_q specifically concentrates in caveolae, whereas G_i and G_s concentrate much more in lipid rafts marked by GPI-anchored proteins (5' nucleotidase and folate receptor). G_q, apparently without $G_{\beta\gamma}$ subunits, stably associates with plasmalemmal and cytosolic caveolin. G_i and G_s interact with $G_{\beta\gamma}$ subunits but not caveolin.G_i and G_s unlike G_q, readily move out of caveolae. Thus, caveolin may function as a scaffold to trap, concentrate, and stabilize G_q preferentially within caveolae over lipid rafts. In N2a cells lacking caveolae and caveolin, G_q, G_i, and G_s all concentrate in lipid rafts as a complex with $G_{\beta\gamma}$. Without effective physiological interaction

with caveolin, G proteins tend by default to segregate in lipid rafts. The ramifications of the segregated microdomain distribution and the G_q-caveolin complex without $G_{\beta\gamma}$ for trafficking, signaling, and mechanotransduction are discussed.

3.183 Depletion of rafts in late endocytic membranes is controlled by NPC1-dependent recycling of cholesterol to the plasma membrane
Lusa, S., et al
J. Cell Sci., ***114(10),*** *1893-1900 (2001)*

In mammalian cells, cholesterol is thought to associate with sphingolipids to form lateral membrane domains termed rafts. Increasing evidence suggests that rafts regulate protein interactions, for example, during signaling, intracellular transport and host-pathogen interactions. Rafts are present in cholesterol-sphingolipid-enriched membranes, including early and recycling endosomes, but whether rafts are found in late endocytic organelles has not been analyzed. In this study, we analyzed the association of cholesterol and late endosomal proteins with low-density detergent-resistant membranes (DRMs) in normal cells and in cells with lysosomal cholesterol-sphingolipid accumulation. In normal cells, the majority of [^{3}H]cholesterol released from [^{3}H]cholesterol ester-LDL associated with detergent-soluble membranes, was rapidly transported to the plasma membrane and became increasingly insoluble with time. In Niemann-Pick C1 (NPC1) protein deficient lipidosis cells, the association of LDL-cholesterol with DRMs was enhanced and its transport to the plasma membrane was inhibited. In addition, the NPC1 protein was normally recovered in detergent-soluble membranes and its association with DRMs was enhanced by lysosomal cholesterol loading. Moreover, lysosomal cholesterol deposition was kinetically paralleled by the sequestration of sphingolipids and formation of multilamellar bodies in late endocytic organelles. These results suggest that late endocytic organelles are normally raft-poor and that endocytosed LDL-cholesterol is efficiently recycled to the plasma membrane in an NPC1-dependent process. The cholesterol-sphingolipid accumulation characteristic to NPC disease, and potentially to other sphingolipidoses, causes an overcrowding of rafts forming lamellar bodies in the degradative compartments.

3.184 The *Leishmania* ATP-binding cassette protein PGPA is an intracellular metal-thiol transporter ATPase
Legare, D., et al
J. Biol. Chem., ***276(28)****, 26301-26307 (2001)*

The *Leishmania* ATP-binding cassette (ABC) transporter PGPA is involved in metal resistance (arsenicals and antimony), although the exact mechanism by which PGPA confers resistance to antimony, the first line drug against *Leishmania*, is unknown. The results of co-transfection experiments, transport assays, and the use of inhibitors suggest that PGPA recognizes metals conjugated to gluthathione or trypanothione, a glutathione-spermidine conjugate present in *Leishmania*. The HA epitope tag of the influenza hemagglutinin as well as the green fluorescent protein (GFP) were fused at the COOH-terminus of PGPA. Immunofluorescence, confocal and electron microscopy studies of the fully functional tagged molecules clearly indicated that PGPA is localized in membranes that are close to the flagellar pocket, the site of endocytosis and exocytosis in this parasite. Subcellular fractionation of *Leishmania tarentolae* PG-PAHA transfectants was performed to characterize further this ABC transporter. The basal PGPA ATPase activity was determined to be 115 nmoles/mg/min. Transport experiments using radioactive arsenite-glutathione conjugates clearly showed that PGPA recognizes and actively transport thiol-metal conjugates. Overall, the results are consistent with PGPA being an intracellular ABC transporter that confers arsenite and antimonite resistance by sequestration of the metal-thiol conjugates.

3.185 Cvt9/Gsa9 functions in sequestering selective cytosolic cargo destined for the vacuole
Kim, J. et al
J. Cell Biol., ***153(2)****, 381-396 (2001)*

Three overlapping pathways mediate the transport of cytoplasmic material to the vacuole in *Saccharomyces cerevisiae*. The cytoplasm to vacuole targeting (Cvt) pathway transports the vacuolar hydrolase, aminopeptidase I (API), whereas pexophagy mediates the delivery of excess peroxisomes for degradation. Both the Cvt and pexophagy pathways are selective processes that specifically recognize their cargo. In contrast, macroautophagy nonselectively transports bulk cytosol to the vacuole for recycling. Most of the import machinery characterized thus far is required for all three modes of transport. However,

unique features of each pathway dictate the requirement for additional components that differentiate these pathways from one another, including at the step of specific cargo selection.

We have identified Cvt9 and its *Pichia pastoris* counterpart Gsa9. In *S. cerevisiae*, Cvt9 is required for the selective delivery of precursor API (prAPI) to the vacuole by the Cvt pathway and the targeted degradation of peroxisomes by pexophagy. In *P. pastoris*, Gsa9 is required for glucose-induced pexophagy. Significantly, neither Cvt9 nor Gsa9 is required for starvation-induced nonselective transport of bulk cytoplasmic cargo by macroautophagy. The deletion of *CVT9* destabilizes the binding of prAPI to the membrane and analysis of a cvt9 temperature-sensitive mutant supports a direct role of Cvt9 in transport vesicle formation. Cvt9 oligomers peripherally associate with a novel, perivacuolar membrane compartment and interact with Apg1, a Ser/Thr kinase essential for both the Cvt pathway and autophagy. In *P. pastoris* Gsa9 is recruited to concentrated regions on the vacuole membrane that contact peroxisomes in the process of being engulfed by pexophagy. These biochemical and morphological results demonstrate that Cvt9 and the *P. pastoris* homologue Gsa9 may function at the step of selective cargo sequestration.

3.186 Low cholesterol stimulates the nonamyloidogenic pathway by its effect on the α-secretase ADAM 10
Kojro, E., Gimpl, G., Lammich, S., Marz, W. and Fahrenholz, F.
Proc. Natl. Acad. Sci., ***98(10),*** *5815-5820 (2001)*

Biochemical, epidemiological, and genetic findings demonstrate a link between cholesterol levels, processing of the amyloid precursor protein (APP), and Alzheimer's disease. In the present report, we identify the α-secretase ADAM 10 (a *d*isintegrin and *m*etalloprotease) as a major target of the cholesterol effects on APP metabolism. Treatment of various peripheral and neutral cell lines with either the cholesterol-extracting agent methyl-β-cyclodextrin or the hydroxymethyl glutaryl-CoA reductase inhibitor lovastin resulted in a drastic increase of secreted α-secretase cleaved soluble APP. This strong stimulatory effect was in the range obtained with phorbol esters and was further increased in cells overexpressing ADAM 10. In cells overexpressing APP, the increase of α-secretase activity resulted in a decreased secretion of Aβ peptides. Several mechanisms were elucidated as being the basis of enhanced α-secretase activity: increased membrane fluidity and impaired internalization of APP were responsible for the effect observed with methyl-β-cyclodextrin; treatment with lovastatin resulted in higher expression of the α-secretase ADAM 10. Our results demonstrate that cholesterol reduction promotes the nonamyloidogenic α-secretase pathway and the formation of neuroprotective α-secretase cleaved soluble APP by several mechanisms and suggest approaches to prevention of or therapy for Alzheimer's disease.

3.187 Neuregulin-1 proteins in rat brain and transfected cells are localized to lipid rafts
Frenzel, K.E. and Falls, D.L.
*J. Neurochem., **77**, 1-12 (2001)*

Neuregulin–1 proteins and their receptors, which are members of the ErbB subfamily of receptor tyrosine kinases, play essential roles in the development of the nervous system and heart. Most neuregulin-1 isoforms are synthesized as transmembrane proproteins that are proteolytically processed to yield an N-terminal fragment containing the bioactive EGF-like domain. In this study we investigated whether neuregulins are found in lipid rafts, membrane microdomains hypothesized to have important roles in signal transduction, protein trafficking, and proteolytic processing. We found that 45% of a 140-kDa neuregulin protein in rat brain synatosomal plasma membrane fractions was insoluble in 1% Triton X-100. Flotation gradient analysis demonstrated the presence of the brain 140-kDa neuregulin protein in low-density fractions enriched in PSD-95, a known lipid raft protein. In transfected cells expressing the neuregulin I-β1a or the III-β1a isoform, most of the neuregulin proprotein was insoluble in 1% Triton X-100, and neuregulin proproteins and C-terminal fragments were detected in lipid raft fractions. In contrast, the III-β1a N-terminal fragment was detected only in the detergent-soluble fraction. These results suggest that localization of neuregulins to lipid rafts may play a role in neuregulin signaling within the nervous system.

3.188 Yeast Rab GTPase-activating protein Gyp1p localizes to the Golgi apparatus and is a negative regulator of Ypt1p
Du, L-L and Novick, P.
*Mol. Biol. Cell, **12**, 1215-1226 (2001)*

A family of related proteins in yeast *Saccharomyces cerevisiae* is known to have in vitro GTPase-activating protein activity on the Rab GTPases. However, their in vivo function remains obscure. One of

them, Gyp1p, acts on Sec4p, Ypt1p, Ypt7p and Ypt51p in vitro. Here, we present data to reveal its in vivo substrate and the role that it plays in the function of the Rab GTPase. Red fluorescent protein-tagged Gyp1p is concentrated on cytoplasmic punctate structures that largely colocalize with a *cis*-Golgi marker. Subcellular fractionation of a yeast lysate confirmed that Gyp1p is peripherally associated with membranes and that it cofractionates with Golgi markers. This localization suggests that Gyp1p may only act on Rab GTPases on the Golgi. A *gyp1Δ* strain displays a growth defect on synthetic medium at 37°C. Overexpression of Ypt1p, but not other Rab GTPases, strongly inhibits the growth of *gyp1*Δ cells. Conversely, a partial loss-of-function allele of *YPT1, ypt1-2*, can suppress the growth defect of *gyp1*Δ cells. Furthermore, deletion of *GYP1* can partially suppress growth defects associated with mutants in subunits of transport protein particle complex, a complex that catalyzes nucleotide exchange on Ypt1p. These results establish that Gyp1p functions on the Golgi as a negative regulator of Ypt1p.

3.189 SNAREs are concentrated in cholesterol-dependent clusters that define docking and fusion sites for exocytosis
Lang, T. et al
EMBO J., ***20(9)***, *2202-2213 (2001)*

During exocytosis, SNARE proteins of secretory vesicles interact with the corresponding SNARE proteins in the plasmalemma to initiate the fusion reaction. However, it is unknown whether SNAREs are uniformly distributed in the membrane or whether specialized fusion sites exist. Here we report that in the plasmalemma, syntaxins are concentrated in 200 nm large, cholesterol-dependent clusters at which secretory vesicles preferentially dock and fuse. The syntaxin clusters are distinct from cholesterol-dependent membrane rafts since they are Triton X-100 soluble and do not co-patch with raft markers. Synaptosomal-associated protein (SNAP)-25 is also clustered in spots, which partially overlap with syntaxin. Cholesterol depletion causes dispersion of these clusters, which is associated with a strong reduction in the rate of secretion, whereas the characteristics of individual exocytic events are unchanged. This suggests that high local concentrations of SNAREs are required for efficient fusion.

3.190 WFS1 (Wolfram syndrome 1) gene product: predominant subcellular localization to endoplasmic reticulum in cultured cells and neuronal expression in rat brain
Takeda, K. et al
Hum. Mol. Genet., ***10(5)***, *477-484 (2001)*

Wolfram (DIDMOAD) syndrome is an autosomal recessive neurodegenerative disorder accompanied by insulin-dependent diabetes mellitus and progressive optic atrophy. Recent positional cloning led to identification of the *WFS1* (Wolfram syndrome 1) gene, a member of a novel gene family of unknown function. In this study, we generated a specific antibody against the C-terminus of the WFS1 protein and investigated its subcellular localization in cultured cells. We also studied its distribution in the rat brain. Biochemical studies indicated the WFS1 protein to be an integral, endoglycosidase H-sensitive membrane glycoprotein that localizes primarily in the endoplasmic reticulum (ER). Consistent with this, immunofluorescence cell staining of overexpressed WFS1 showed a characteristic reticular pattern over the cytoplasm and overlapped with the ER marker staining. No co-localization of WFS1 with mitochondria argues against an earlier clinical hypothesis that Wolfram syndrome is a mitochondria-mediated disorder. In the rat brain, at both the protein and mRNA level, WFS1 was found to be present predominantly in selected neurons in the hippocampus CA1, amygdaloid areas, olfactory tubercle and superficial layer of the allocortex. These expression sites, i.e. components of the limbic system or structures closely associated with this system, may be involved in the psychiatric, behavioral and emotional abnormalities characteristic of this syndrome. ER localization of WFS1 suggests that this protein plays an as yet undefined role in membrane trafficking, protein processing and/or regulation of ER calcium homeostasis. These studies represent a first step toward the characterization of WFS1 protein, which presumably functions to maintain certain populations of neuronal and endocrine cells.

3.191 Regulation of tumor angiogenesis by oxygen-regulated protein 150, an inducible endoplasmic reticulum chaperone
Ozawa, K. et al
Cancer Res., ***61***, *4206-4213 (2001)*

Expression of angiogenic factors such as vascular endothelial growth factor (VEGF) under conditions of cell stress involves both transcriptional and translational events, as well as an important role for inducible endoplasmic reticulum (ER) chaperones. Coexpression of VEGF and 150-kDa oxygen-regulated protein

(ORP), a novel ER chaperone, in human glioblastoma suggested a link between angiogenesis and ORP150. C6 glioma cells stably transfected with ORP150 antisense displayed selectively reduced ORP150 expression. Tumors raised after inoculation of immuno-compromised mice with ORP150 antisense C6 glioma transfect-ants demonstrated an initial phase of growth comparable to wild-type C6 glioma cells which was followed by marked regression within 8 days. Decreased density of platelet/endothelial cell adhesion molecule 1-positive structures within the tumor bed was consistent with reduced angiogenesis in C6 gliomas expressing ORP150 antisense, compared with tumors derived from C6 cells overexpressing ORP150 sense or vector controls. *In vitro*, inhibition of ORP150 expression decreased release of VEGF into culture supernatants; in ORP150 antisense transfectants, VEGF accumulated intracellularly within the ER. These findings demons-trate a critical role for the inducible ER chaperone ORP150 in tumor-mediated angiogenesis via processing of VEGF, and thus, highlight a new facet of mechanism amenable to therapeutic manipulation in tumors.

3.192 Subcellular compartment and molecular subdomain of β-amyloid precursor protein relevant to the Aβ42-promoting effects of Alzheimer mutant presenilin 2
Iwata, H., Tomita, T., Maruyama, H. And Iwatsubo, T.
J. Biol. Chem., ***276(24)***, *21678-21685 (2001)*

Increased production of amyloidβ peptides ending at position 42 (Aβ42) is one of the pathogenic phenotypes caused by mutant forms of presenilins (PS) linked to familial Alzheimer's disease. To identify the subcellular compartment(s) in which familial Alzheimer's disease mutant PS2 (mt PS2) affects the γ-cleavage of βAPP to increase Aβ42, we co-expressed the C-terminal 99-amino acid fragment of βAPP (C100) tagged with sorting signals to the endoplasmic reticulum (C100/ER) or to the *trans*-Golgi network (C100/TGN) together with mt PS2 in N2a cells. C100/TGN co-transfected with mt PS2 increased levels or ratios of intracellular as well as secreted Aβ42 at similar levels to those with C100 without signals (C100/WT), whereas C100/ER yielded a negligible level of Aβ, which was not affected by co-transfection of mt PS2. To identify the molecular subdomain of βAPP required for the effects of mt PS2, we next co-expressed C100 variously truncated at the C-terminal cytoplasmic domain together with mt PS2. All types of C-terminally truncated C100 variants including that lacking the entire cytoplasmic domain yielded the secreted form of Aβ at levels comparable with those from C100/WT, and co-transfection of mt PS2 increased the secretion of Aβ42. These results suggest that (i) late intracellular compartments including TGN are the major sites in which Aβ42 is produced and up-regulated by mt PS2 and that (ii) the anterior half of C100 lacking the entire cytoplasmic domain is sufficient for the overproduction of Aβ42 caused by mt PS2.

3.193 *Toxoplasma* evacuoles: a two-step process of secretion and fusion forms the parasitophorous vacuole
Hakansson, S., Charron, A.J. and Sibley, L.D.
The EMBO J., ***20(12)***, *3132-3144 (2001)*

Rapid discharge of secretory organelles called rhoptries is tightly coupled with host cell entry by the protozoan parasite *Toxoplasma gondii*. Rhoptry contents were deposited in clusters of vesicles within the host cell cytosol and within the parasitophorous vacuole. To examine the fate of these rhoptry-derived secretory vesicles, we utilized cytohalasin D to prevent invasion, leading to accumulation of protein-rich vesicles in the host cell cytosol. These vesicles lack an internal parasite and are hence termed evacuoles. Like the mature parasite-containing vacuole, evacuoles became intimately associated with host cell mitochondria and endoplasmic reticulum, while remaining completely resistant to fusion with host cell endo-somes and lysosomes. In contrast, evacuoles were recruited to pre-existing, parasite-containing vacuoles and were capable of fusing and delivering their contents to these compartments. Our findings indicate that a two-step process involving direct rhoptry secretion into the host cell cytoplasm followed by incorporation into the vacuole generates the parasitophorous vacuole occupied by *Toxoplasma*. The characteristic properties of the mature vacuole are likely to be determined by this early delivery of rhoptry components.

3.194 Rapid changes in polyphosphate content within acidocalcisomes in response to cell growth, differentiation and environmental stress in *Trypanosoma cruzi*
Ruiz, F.A., Rodrigues, C.O. and Docampo, R.
J. Biol. Chem., ***276(28)***, *26114-26121 (2001)*

Inorganic polyphosphate (polyP) has been identified and measured in different stages of *Trypanosoma cruzi*. Millimolar levels (in terms of P_i residues) in chains of less than 50 residues long, and micromolar levels in chains of about 700-800 residues long, were found in different stages of *T. cruzi*. Analysis of purified *T. cruzi* acidocalcisomes indicated that polyPs were preferentially located in these organelles. This was confirmed by visualization of polyPs in the acidocalcisomes using 4,6-diamidino-2-phenylindole (DAPI). A rapid increase (within 2-4 h) in the levels of short and long-chain polyPs was detected during trypomastigote to amastigote differentiation and during the lag phase of growth of epimastigotes (within 12-24 h). Levels rapidly decreased after epimastigotes resumed growth. Short– and long-chain polyP levels rapidly decreased upon exposure of epimastigotes to hypo-osmotic or alkaline stresses while levels increased after hyperosmotic stress. Ca^{2+} release from acidocalcisomes by a combination of ionophores (ionomycin, nigericin) was associated with the hydrolysis of short – and long-chain polyPs. In agreement with these results, acidocalcisomes were shown to contain polyphosphate kinase and exopolyphosphatase activities. Together, these results suggest a critical role for these organelles in the adaptation of the parasite to environmental changes.

3.195 Apg2 is a novel protein required for the cytoplasm to vacuole targeting, autophagy, and pexophagy pathways

Wang, C-W., et al
J. Biol. Chem, ***276(32)****, 30442-30451 (2001)*

To survive starvation conditions, eukaryotes have developed an evolutionarily conserved process, termed autophagy, by which the vacuole/lysosome mediates the turnover and recycling of non-essential intracellular material for re-use in critical biosynthetic reactions. Morphological and biochemical studies in *Saccharomyces cerevisiae* have elucidated the basic steps and mechanisms of the autophagy pathway. Although it is a degradative process, autophagy shows substantial overlap with the biosynthetic cytoplasm to vacuole targeting (Cvt) pathway that delivers resident hydrolases to the vacuole. Recent molecular genetics analyses of mutants defective in autophagy and the Cvt pathway, *apg*, *aut* and *cvt*, have begun to identify the protein machinery and provide a molecular resolution of the sequestration and import mechanism that are characteristic of these pathways. In this study, we have identified a novel protein, termed Apg2, required for both the Cvt and autophagy pathways as well as the specific degradation of peroxisomes. Apg2 is required for the formation and/or completion of cytosolic sequestering vesicles that are required for vacuolar import through both the Cvt pathway and autophagy. Biochemical studies revealed that Apg2 is a peripheral membrane protein. Apg2 localizes to the previously identified perivacuolar compartment that contains Apg9, the only characterized integral membrane protein that is required for autophagosome/Cvt vesicle formation.

3.196 Apg2p functions in autophagosome formation on the perivacuolar structure

Shintani, T., Suzuki, K., Kamada, Y., Noda, T. and Ohsumi,Y.
J. Biol. Chem., ***276(32)****, 30452-30460 (2001)*

Autophagy is a degradative process in which cytoplasmic components are non-selectively sequestered by double-membrane structures, termed autophagosomes, and transported to the vacuole. We have identified and characterized a novel protein Apg2 essential for autophagy in yeast. Biochemical and fluorescence microscopic analyses indicate that Apg2p functions at the step of autophagosome formation. Apg2p localizes to some membranous structure distinct from any known organelle. Using fluorescent protein-tagged Apg2p, we showed that Apg2p localizes to a dot structure close to the vacuole, where Apg8p also exists, but not on autophagosomes unlike Apg8p. This punctate localization of Apg2p depends on the function of Apg1p kinase, phosphatidylinositol-3 kinase complex and Apg9p. $Apg2p^{G83E}$, encoded by an *apg2-2* allele, shows a severely reduced activity of autophagy and a dispersed localization in the cytoplasm. Overexpression of the mutant Apg2p lessens the defect in autophagy. These results suggest that the dot structure is physiologically important. Apg2p and Apg8p are independently recruited to the structure but coordinately function there to form the autophagosome.

3.197 Cross-talk between caveolae and glycosylphosphatidylinositol-rich domains

Abrami, L., et al.
J. Biol. Chem., ***276(33)****, 30729-30736 (2001)*

Most mammalian cells have in their plasma membrane at least two types of lipid microdomains, non-invaginated lipid rafts and caveolae. Glycosylphosphatidylinositol (GPI)-anchored proteins constitute a class of proteins that are enriched in rafts but not caveolae at steady state. We have analyzed what the

effects of abolishing GPI-biosynthesis are on rafts, caveolae and cholesterol levels. GPI-deficient cells were obtained by screening for resistance to the pore-forming toxin aerolysin, which uses this class of proteins as receptors. Despite the absence of GPI-anchored proteins, mutant cells still contained lipid rafts indicating that GPI-anchored proteins are not crucial structural elements of these domains. Interestingly, the caveolae-specific membrane proteins, caveolin 1 and 2, were up regulated in GPI-deficient cells, in contrast to flotillin-1 and GM1, which were expressed at normal levels. Also the number of surface caveolae was increased. This effect was specific since recovery of GPI biosynthesis by gene recomplementation, restored caveolin expression and the number of surface caveolae to wild type levels. The inverse correlation between the expression of GPI-anchored proteins and caveolin-1 was confirmed by the observation that overexpression of caveolin-1 in wild type cells led to a decrease in the expression of GPI-anchored proteins. In cells lacking caveolae, the absence of GPI-anchored proteins caused an increase in cholesterol levels suggesting a possible role of GPI-anchored proteins in cholesterol homeostasis, which in some cells, such as Chinese hamster ovary cells, can be compensated by caveolin up regulation.

3.198 Heterogeneous fatty acylation of Src family kinases with polyunsaturated fatty acids regulates raft localization and signal transduction
Liang, X et al
J. Biol. Chem., ***276(33)****, 30987-30994 (2001)*

Fatty acylation of Src family kinases is essential for localization of the modified proteins to the plasma membrane and to plasma membrane rafts. It has been suggested that the presence of saturated fatty acyl chains on proteins is conducive for their insertion into the liquid ordered lipid domains present in rafts. The ability of unsaturated dietary fatty acids to be attached to Src family kinases has not been investigated. Here, we demonstrate that heterogeneous fatty acylation of Src family kinases occurs and that the nature of the attached fatty acid influences raft-mediated signal transduction. By using matrix-assisted-laser-desorption/ionization time-of-flight mass spectrometry, we show that in addition to 14:0 (myristate), 14:1 and 14:2 fatty acids can be attached to the N-terminal glycine of the Src family kinase Fyn when the growth media is supplemented with these dietary fatty acids. Moreover, we synthesized novel iodinated analogs of oleate and stearate, and showed that heterogeneous S-acylation can occur on cysteine residues within Fyn as well as Gα, GAP43 and Ras. Modification of Fyn with unsaturated or polyunsaturated fatty acids reduced its raft localization and resulted in decreased T cell signal transduction. These studies establish that heterogeneous fatty acylation is a widespread occurrence that serves to regulate signal transduction by membrane bound proteins.

3.199 Lipoprotein lipase and leptin are accumulated in different secretory compartments in rat adipocytes
Roh, C., Roduit, R., Thorens, B., Fried, S. and Kandror, K.V.
J. Biol. Chem., ***276(38)****, 35990-35994 (2001)*

Adipose cells produce and secrete several physiologically proteins, such as lipoprotein lipase (LPL), leptin, adipsin, Acrp30, etc. However, secretory pathways in adipocytes have not been characterized, and vesicular carriers responsible for accumulation and transport of secreted proteins have not been identified. We have compared the intracellular localization of two proteins secreted from adipose cells: leptin and LPL. Adipocytes accumulate large amounts of both proteins, suggesting that neither of them is targeted to the constitutive secretory pathway. By means of velocity centrifugation in sucrose gradients, equilibrium density centrifugation in **iodixanol** gradients and immunofluorescence confocal microscopy, we determined that LPL and leptin were localized in different membrane structures. LPL was found mainly in the endoplasmic reticulum with a small pool being present in low-density membrane vesicles that may represent a secretory compartment in adipose cells. Virtually all intracellular leptin was localized in these low-density secretory vesicles. Insulin-sensitive Glut4-vesicles did not contain either LPL or leptin. Thus, secretion from adipose cells is controlled both at the exit from the endoplasmic reticulum as well as at the level of "downstream" secretory vesicles.

3.200 Activation of mitogen-activated protein kinase by membrane targeted Raf chimeras is independent of raft localization
Chen, X. and Resh, M.D.
J. Biol. Chem., ***276(37)****, 34617-34623 (2001)*

Binding of proteins to the plasma membrane can be achieved with various membrane targeting motifs, including combinations of fatty acids, isoprenoids, and basic domains. In this study, we investigate whether attachment of different membrane targeting motifs influences the signaling capacity of membrane-

bound signal transduction proteins by directing the proteins to different membrane microdomains. We used c-Raf-1 as a model for a signaling protein that is activated when membrane-bound. Three different membrane targeting motifs from K-Ras, Fyn and Src proteins were fused to the N- or C-terminus of Raf-1. The ability of the modified Rafs to initiate MAPK signaling was then investigated. All three modified Raf-1 constructs activated MAPK to nearly equivalent levels. The extent of localization of the Raf-1 constructs to membrane microdomains known as rafts did not correlate with the level of MAPK activation. Moreover, treatment of cells with the raft disrupting drug methyl-β-cyclodextrin (MβCD) caused activation of MAPK to levels equivalent to those achieved with membrane targeted Raf constructs. The use of pharmacological agents as well as dominant mutants revealed that MAPK activation by MβCD proceeds via a PI3K dependent mechanism that is Ras/Raf independent. We conclude that cholesterol depletion from the plasma membrane by MβCD constitutes an alternative pathway for activating MAPK.

3.201 Biochemical and morphological analysis on the localization of Rac1 in neurons
Kumanogoh, H., Miyata, S., Sokawa, Y. and Maekawa, S.
*Neuroscience Res., **39**, 189-196 (2001)*

The acquisition of cell type-specific morphologies is a central feature of neuronal differentiation. Many extra- and intracellular signals are known to cause the morphological changes of neuronal cells through the reconstruction of the microfilaments underneath the cell membrane. The membrane microdomain called "raft" has been paid much attention, for this domain contains many signal-transducing molecules including trimeric G proteins and cytoskeletal proteins. The raft domain is recovered in a low-density fraction after the treatment of the membrane with the non-ionic detergent such as Triton X-100 and the enrichment of cholesterol and sphingolipids is ascribed to be responsible for the detergent insolubility. In contrast to the well-known localization of trimeric G proteins in raft, the localization of small G proteins in the raft is poorly characterized. Since Rho family small G proteins (Rho, Rac, and Cdc42) regulate the microfilament system, we studied the localization of Rho family small G proteins in the raft of rat brain with western blotting. Specific localization of Rac1 was detected in the raft from 1-day-old and 8-week-old rat whole brain, and also in the raft prepared from the growth cone and synaptic plasma membrane fractions. Rho and Cdc42 were, in contrast, recovered in the Triton soluble fraction. Double immunostaining of cultured hippocampal neurons with antibodies to Rac1 and MAP-2, or Rac1 and tau, showed punctate distribution of Rac1 in axons as well as in dendrites.

3.202 Serum-activated assembly and membrane translocation of an endogenous Rac1: effector complex
Hansen, M.D.H. and Nelson, W.J.
*Current Biology, **11**, 356-360 (2001)*

Rho family GTPases (Cdc42, Rac1, and RhoA) function downstream of Ras, and in a variety of cellular processes. Studies to examine these functions have not directly linked endogenous protein interactions with specific in vivo functions of Rho GTPases. Here, we show that endogenous Rac1 and two known binding partners, Rho GDP dissociation inhibitor (RhoGDI) and p21-activated kinase (PAK), fractionate as distinct cytosolic complexes. A Rac1: PAK complex is translocated from the cytosol to ruffling membranes upon cell activation by serum. Overexpression of dominant-negative (T17N) Rac1 does not affect the assembly or distribution of this Rac1: PAK complex. This is the first direct evidence of how a specific function of Rac1 is selected by the assembly and membrane translocation of a distinct Rac1:effector complex.

3.203 Subcellular study of sphingoid base phosphorylation in rat tissues: evidence for multiple sphingosine kinases
Gijsbers, S., Van der Hoeven, G. And Van Veldhoven, P.P.
*Biochim. Biophys. Acta, **1532**, 37-50 (2001)*

The enzymatic phosphorylation of sphingoid bases was analysed in rat tissues, using D-*erythro*-[4,5-^{3}H]sphinganine as substrate. After optimization of the assay, taking care to block sphingosine-phosphate lyase and sphingosine phosphatase, highest ATP-dependent kinase activities were present in testis, followed by kidney, and intestinal mucosa. Approximately two thirds of the kidney activity was membrane bound, the remaining being cytosolic. Classical cell fractionation studies of a particulate fraction from kidney homogenates by Percoll gradient and sucrose density gradient centrifugation revealed that kinase activities are associated with vesicles derived from the endoplasmic reticulum and the plasma membrane. Based on indirect data, such as the effect of detergents and divalent ions, the cytosolic and both membrane

bound activities appear to reside in different proteins. *N,N*-dimethylsphingenine was inhibitory to all three different kinases, which were mainly active towards the D-erythro isomers of sphingenine and sphinganine.

3.204 GPI-anchored proteins and glycoconjugates segregate into lipid rafts in Kinetoplastida
Denny, P.W., Field, M.C. and Smith, D.F.
FEBS Lett., ***491***, *148-153 (2001)*

The plasma membranes of the divergent eukaryotic parasites, *Leishmania* and *Trypanosoma*, are highly specialized, with a thick coat of glycoconjugates and glycoproteins playing a control role in virulence. Usually, the majority of these surface macromolecules are attached to the plasma membrane via a glycosylphosphatidylinositol (GPI) anchor. In mammalian cells and yeast, many GPI-anchored molecules associate with sphingolipid and cholesterol-rich detergent-resistant membranes, known as lipid rafts. Here we show that GPI-anchored parasite macromolecules (but not the dual acylated *Leishmania* surface protein (hydrophilic acylated surface protein) or a subset of the GPI-anchored glycoinositol phopholipid glycolipids) are enriched in a sphingolipid/sterol-rich fraction resistant to cold detergent extraction. This observation is consistant with the presence of functional lipid rafts in these ancient, highly polarized organisms.

3.205 Endoplasmic reticulum and *cis*-Golgi localization of human T-lymphotropic virus type 1 $p12^I$: association with calreticulin and calnexin
Ding, W. et al
J. Virol., ***75(16)***, *7672-7682 (2001)*

Human T-lymphotropic virus type 1 (HTLV-1) is a complex retrovirus encoding regulatory and accessory genes in four open reading frames (ORF I to IV) of the pX region. We have demonstrated an important role of pX ORF I expression, which encodes $p12^I$, in establishment of HTLV-1 in a rabbit model and for optimal viral infectivity in quiescent primary lymphocytes. These data indicated that $p12^I$ may enhance lymphocyte activation and thereby promote virus infection. To further define the role of $p12^I$ in cell activation, we characterized the subcellular localization of $p12^I$ transfected 293T cells and HeLa-Tat cells by multiple methods, including immunofluorescence confocal microscopy, and subcellular fractionation. Herein, we demonstrate that $p12^I$ accumulates in the endoplasmic reticulum (ER) and *cis*-Golgi apparatus. The localization of $p12^I$ was unchanged following treatments with both cycloheximide (blocking de novo protein synthesis) and brefeldin A (disrupting ER-to-Golgi protein transport), indicating that the protein is retained in the ER and *cis*-Golgi. Moreover, using coimmunoprecipitation assays, we identify the direct binding of $p12^I$ with both calreticulin and calnexin, resident ER proteins which regulate calcium storage. Our results indicate that $p12^I$ directly binds key regulatory proteins involved in calcium-mediated cell signalling and suggest a role of $p12^I$ in the establishment of HTLV-1 by activation of host cells.

3.206 Multimerization of human immunodeficiency virus type 1 Gag promotes its localization to barges, raft-like membrane microdomains
Lindwasser, O.W. and Resh, M.D.
J. Virol., ***75(17)***, *7913-7924 (2001)*

The Gag polyprotein of human immunodeficiency virus type 1 (HIV-1) organizes the assembly of nascent virions at the plasma membrane of infected cells. Here we demonstrate that a population of Gag is present in distinct raft-like membrane microdomains that we have termed “barges”. Barges have a higher density than standard rafts, most likely due to the presence of oligomeric Gag-Gag assembly complexes. The regions of the Gag protein responsible for barge targeting were mapped by examining the flotation behavior of wild-type and mutant proteins on **OptiPrep** density gradients. N-myristoylation of Gag was necessary for association with barges. Removal of the NC and p6 domains shifted much of the Gag from barges into typical raft fractions. These data are consistent with a model in which multimerization of myristoylated Gag proteins drive association of Gag oligomers into raft-like barges. The functional significance of barge association was revealed by several lines of evidence. First, Gag isolated from virus-like particles was almost entirely localized in barges. Moreover, a comparison of wild-type Gag with Fyn(10)Gag, a chimeric protein containing the N-terminal sequence of Fyn, revealed that Fyn(10)Gag exhibited increased affinity for barges and a two- to fourfold increase in particle production. These results imply that association of Gag with raft-like barge membrane microdomains plays an important role in the HIV-1 assembly process.

3.207 Segregation of leading-edge and uropod components into specific lipid rafts during T cell polarization

Gomez-Mouton, C. et al

*Proc. Natl. Acad, Sci., USA, **98(17)**, 9642-9647 (2001)*

Redistribution of specialized molecules in migrating cells develops asymmetry between two opposite cell poles, the leading edge and the uropod. We show that acquisition of a motile phenotype in T lymphocytes results in the asymmetric redistribution of ganglioside GM3- and GM1-enriched raft domains to the leading edge and to the uropod, respectively. This segregation to each cell pole parallels the specific redistribution of membrane proteins associated to each raft subfraction. Our data suggest that raft partitioning is a major determinant for protein redistribution in polarized T cells, as ectopic expression of raft-associated proteins results in their asymmetric redistribution, whereas non-raft partitioned mutants of these proteins are distributed homogeneously in the polarized cell membrane. Both acquisition of a migratory phenotype and SDF-1 α-induced chemotaxis are cholesterol depletion-sensitive. Finally, GM3 and GM1 raft redistribution requires an intact actin cytoskeleton, but is insensitive to microtubule disruption. We propose that membrane protein segregation not only between raft and nonraft domains but also between distinct raft subdomains may be an organizational principle that mediates redistribution of specialized molecules needed for T cell migration.

3.208 The Sec6/8 complex in mammalian cells: characterization of mammalian Sec3, subunit interactions, and expression of subunits in polarized cells

Matern, H.T., Yeaman, C., Nelson, W.J. and Scheller, R.H.

*Proc. Natl. Acad. Sci, USA, **98(17)**, 9648-9653 (2001)*

The yeast exocyst complex (also called Sec6/8 complex in higher eukaryotes) is a multiprotein complex essential for targeting exocytic vesicles to specific docking sites on the plasma membrane. It is composed of eight proteins (Sec3, -5, -6, -8, -10, and -15, and Exo70 and -84), with molecular weights ranging from 70 to 144 kDa. Mammalian orthologues for seven of these proteins have been described and here we report the cloning and initial characterization of the remaining subunit, Sec3. Human Sec3 (hSec3) shares 17% sequence identity with yeast Sec3p, interacts in the two-hybrid system with other subunits of the complex (Sec5 and Sec8), and is expressed in almost all tissues tested. In yeast, Sec3p has been proposed to be a spatial landmark for polarized secretion (1), and its localization depends on its interaction with Rho1p (2). We demonstrate here that hSec3 lacks the potential Rho1-binding site and GFP-fusions of hSec3 are cytosolic. Green fluorescent protein (GFP)-fusion of nearly every subunit of the mammalian Sec6/8 complex were expressed in Madin-Darby canine kidney (MDCK) cells, but they failed to assemble into a complex with endogenous proteins and localized in the cytosol. Of the subunits tested, only GFP-Exo70 localized to lateral membrane sites of cell-cell contact when expressed in MDCK cells. Cells overexpressing GFP-Exo70 fail to form a tight monolayer, suggesting the Exo70 targeting interaction is critical for normal development of polarized epithelial cells.

3.209 Nerve growth factor activates persistent Rap1 signaling in endosomes

Wu, C., Lai, C-F. and Mobley, W.C.

*J. Neurosci., **21(15)**, 5406-5416 (2001)*

We investigated a role for endogenous Rap1, a small monomeric GTP-binding protein of the Ras family, in nerve growth factor (NGF) signaling in PC12 cells. Although both epidermal growth factor (EGF) and NGF caused transient activation of Ras, only NGF induced the activation of Rap1. Moreover, Rap1 activation was sustained for hours, an effect that matched the sustained activation of the mitogen-activated protein kinase (MAPK) pathway. To investigate the molecular basis for Rap1 activation, we examined complexes containing C3G, a guanine nucleotide exchange factor for Rap1, and CrkL, an adapter protein known to influence Rap1 signaling. NGF induced the formation of a long-lived complex containing C3G/CrkL/Shp2/Gab2/TrkA. Linking the complex to Rap1 activation, we coprecipitated activated TrkA and activated MAPK with activated Rap1 in NGF-treated cells. Confocal microscopy and subcellular fractionation showed that activated Rap1 and the other proteins of the signaling complex were present in endosomes. Pretreatment of PC12 cells with brefeldin A (BFA), which disrupts the Golgi and endosomal compartments, had little effect on Ras activation but strongly inhibited NGF-induced Rap1 activation and continuing MAPK activation. We propose that endosomes are a site from which NGF induces the prolonged activation of Rap1 and MAPK.

3.210 The first proline of PALP motif at the C terminus of presenilins is obligatory for stabilization, complex formation, and γ-secretase activities of presenilins
Tomita, T. et al
J. Biol. Chem., ***276(35),*** *33273-33281 (2001)*

Mutations in presenilin (PS) genes cause early-onset familial Alzheimer's disease by increasing production of the amyloidogenic form of amyloid β peptides ending at residue 42 (Aβ42). PS is an evolutionarily conserved multipass transmembrane protein, and all known PS proteins contain a proline-alanine-leucine-proline (PALP) motif starting at proline (P) 414 (amino acid numbering based on human PS2) at the C terminus. Furthermore, missense mutations that replace the first proline of PALP with leucine (P414L) lead to a loss-of-function of PS in *Drosophila melanogaster* and *Caenorhabditis elegans*. To elucidate the roles of the PALP motif in PS structure and function, we analyzed neuro2a as well as PS1/2 null fibroblast cell lines transfected with human PS harboring mutations at the PALP motif. P414L mutation in PS2 (and its equivalent in PS1) abrogated stabilization, high molecular weight complex formation, and entry to Golgi/*trans*-Golgi network of PS proteins, resulting in failure of Aβ42 overproduction on familial Alzheimer's disease mutant basis as well as of site-3 cleavage of Notch. These data suggest that the first proline of the PALP motif plays a crucial role in the stabilization and formation of the high molecular weight complex of PS, the latter being the active form with intramembrane proteolytic activities.

3.211 A role for smooth endoplasmic reticulum membrane cholesterol ester in determining the intracellular location and regulation of sterol-regulatory element-binding protein-2
Iddon, R. et al
Biochem. J., ***358****, 415-422 (2001)*

Cellular cholesterol homoeostasis is regulated through proteolysis of the membrane-bound precursor sterol-regulatory element-binding protein (SREBP) that releases the mature transcription factor form, which regulates gene expression. Our aim was to identify the nature and intracellular site of the putative sterol-regulatory pool which regulates SREBP proteolysis in hamster liver. Cholesterol metabolism was modulated by feeding hamsters control chow, or a cholesterol-enriched diet, or by treatment with simvastatin or with the oral acyl-CoA: cholesterol acyltransferase inhibitor C1-1011 plus cholesterol. The effects of the different treatments on SREBP activation were confirmed by determination of the mRNAs for the low-density lipoprotein receptor and hydroxymethylglutaryl-CoA (HMG-CoA) reductase and by measurement of HMG-CoA reductase activity. The endoplasmic reticulum was isolated from livers and separated into subfractions by centrifugation in self-generating iodixanol gradients. Immunodetectable SREBP-2 accumulated in the smooth endoplasmic reticulum of cholesterol-fed animals. Cholesterol ester levels of the smooth ER membrane (but not the cholesterol levels) increased after cholesterol feeding and fell after treatment with simvastatin or C1-1011. The results suggest that an increased cellular cholesterol load causes accumulation of SREBP-2 in the smooth endoplasmic reticulum and, therefore, that membrane cholesterol ester may be one signal allowing exit of the SREBP-2/SREBP-cleavage-regulating protein complex to the Golgi.

3.212 Intracellular distribution of lysosomal sialidase is controlled by the internalisation signal in its cytoplasmic tail
Lukong, K.E. et al
J. Biol. Chem., ***276(49)****, 46172-46181 (2001)*

Sialidase (neuraminidase), encoded by the *neu-1* gene in the major histocompatibility complex locus catalyzes the intralysosomal degradation of sialylated glycoconjugates. Inherited deficiency of sialidase results in sialidosis or galactosialidosis, both severe metabolic disorders associated with lysosomal storage of oligosaccharides and glycopeptides. Sialidase also plays an important role in cellular signaling and is specifically required for the production of cytokine interleukin-4 by activated T lymphocytes. In these cells, *neu-1*-encoded sialidase activity is increased on the cell surface, suggesting that a specific mechanism regulates sorting of this enzyme to the plasma membrane. We investigated that mechanism by first showing that sialidase contains the internalization signal found in lysosomal membrane proteins targeted to endosomes via clathrin-coated pits. The signal consists of a C-terminal tetrapeptide ^{412}YGTL^{415}, with Tyr^{412} and Leu^{415} essential for endocytosis of the enzyme. We further demonstrated that redistribution of sialidase from lysosomes to the cell surface of activated lymphocytes is accompanied by increased reactivity of the enzyme with antiphosphotyrosine antibodies. We speculate that phosphorylation of Tyr^{412} results in inhibition of sialidase internalization in activated lymphocytes.

3.213 Involvement of lipid rafts in nephrin phosphorylation and organization of the glomerular slit diaphragm

Simons, M. et al

Am. J. Pathol., ***159(3)****, 1069-1077 (2001)*

NPHS1 has recently been identified as the gene whose mutations cause congenital nephrotic syndrome of the Finnish type. The respective gene product nephrin is a transmembrane protein expressed in glomerular podocytes and primarily localized to the glomerular slit diaphragm. This interpodocyte junction functions in the glomerular filtration by restricting the passage of plasma proteins into the urinary space in a size-selective manner. The functional role of nephrin in this filtration process is so far not very well understood. In this study, we show that nephrin associates in an oligomerized form with signaling microdomains, also known as lipid rafts, and that these localize to the slit diaphragm. We also show that the nephrin-containing rafts can be immunoisolated with the 27A antibody recognizing a podocyte-specific 9-O-acetylated GD3 ganglioside. In a previous study it has been shown that the *in vivo* injection of this antibody leads to morphological changes of the filtration slits resembling foot process effacement. Here, we report that, in this model of foot process effacement, nephrin dislocates to the apical pole of the narrowed filtration slits and also that it is tyrosine phosphorylated. We suggest that lipid rafts are important in the spatial organization of the glomerular slit diaphragm under physiological and pathological conditions.

3.214 Presenilin, notch, and the genesis and treatment of Alzheimer's disease

Selkoe, D.J.

Proc. Natl. Acad, Sci., ***98(20)****, 111039-11041 (2001)*

Elucidation of the proteolytic processing of the amyloid β-protein precursor (APP) has revealed that one of the two proteases (γ-secretase) that cleave APP to release amyloid-β protein (Aβ) is likely to be presenilin. Presenilin also mediates the γ-secretase-like cleavage of Notch receptors to enable signaling by their cytoplasmic domains. Therefore, APP and Notch may be the first identified substrates of a unique intramembranous aspartyl protease that has presenilin as its active-site component. In view of the evidence for a central role of cerebral build-up of Aβ in the pathogenesis of Alzheimer's disease, this disorder appears to have risen in the human population as a late-life consequence of the conservation of a critical developmental pathway.

3.215 Cellular membrane-binding ability of the C-terminal cytoplasmic domain of human immunodeficiency virus type 1 envelope transmembrane protein gp41

Chen, S.S-L., Lee, S-F. and Wang, C-T.

J. Virol., ***75(20)****, 9925-9938 (2001)*

The amphipathic α-helices located in the cytoplasmic tail of the envelope (Env) transmembrane glycoprotein gp41 of human immunodeficiency virus type 1 have been implicated in membrane association and cytopathicity. Deletion of the last 12 amino acids in the C terminus of this domain severely impairs infectivity. However, the nature of the involvement of the cytoplasmic tail in Env-membrane interactions in cells and the molecular basis for the defect in infectivity of this mutant virus are still poorly understood. In this study we examined the interaction of the cytoplasmic tail with membranes in living mammalian cells by expressing a recombinant cytoplasmic tail fragment and an *Escherichia coli* β-galactosidase/cytoplasmic tail fusion protein, both of them lacking gp120, the gp41 ectodomain, and the transmembrane region. We found through cell fractionation, in vivo membrane flotation, and confocal immunofluorescence studies that the cytoplasmic tail contained determinants to be routed to a perinuclear membrane region in cells. Further mapping showed that each of the three lentivirus lytic peptide (LLP-1, LLP-2, and LLP-3) sequences conferred this cellular membrane-targeting ability. Deletion of the last 12 amino acids from the C terminus abolished the ability of the LLP-1 motif to bind to membranes. High salt extraction, in vitro transcription and translation, and posttranslational membrane binding analyses indicated that the β-galactosidase/LLP fusion proteins were inserted into membranes via the LLP sequences. Subcellular fractionation and confocal microscopy studies revealed that each of the LLP motifs, acting in a position-independent manner, targeted non-endoplasmic reticulum (ER)-associated-β-galactosidase and enhanced green fluorescence protein to the ER. Our study provides a basis for the involvement of the gp41 cytoplasmic tail during Env maturation and also supports the notion that the membrane apposition of the C-terminal cytoplasmic tail plays a crucial role in virus-host interaction.

3.216 The polyphosphate bodies of *Chlamydomas reinhardtii* possess a proton pumping pyrophosphatase and are similar to acidocalcisomes

Ruiz, F.A., Marchesini, N., Seufferheld, M., Govindjee and Docampo, R.
J. Biol. Chem., ***276/49***, *46196-46203 (2001)*

Acidocalcisomes are acidic calcium storage compartments described initially in trypanosomatid and apicomplexan parasites. In this work, we describe organelles with properties similar to acidocalcisomes in the green alga *Chlamydomonas reinhardtii*. Nigericin and NH_4CL released $^{45}Ca^{2+}$ from preloaded permeabilized cells suggesting the incorporation of a significant amount of this cation into an acidic compartment. X-ray microanalysis of the electron-dense vacuoles or polyphosphate bodies of *C. reinhardtii* showed large amounts of phosphorus, magnesium, calcium, and zinc. Immunofluorescence microscopy, using antisera raised against a peptide sequence of the vacuolar-type proton pyrophosphatase (H^+-PPase) of *Arabidopsis thaliana* which is conserved in the *C. reinhardtii* enzyme, indicated localization in the plasma membrane, in intracellular vacuoles and the contractile vacuole where it co-localized with the vacuolar proton ATPase (V-H^+-ATPase). Purification of the electron-dense vacuoles using **iodixanol** density gradients indicated a preferential localization of the H^+-PPase and the V-H^+-ATPase activities in addition to high concentrations of PP_i and short and long chain polyphosphate, but lack of markers for mitochondria and chloroplasts. In isolated electron-dense vacuoles, PP_i-driven proton translocation was stimulated by potassium ions and inhibited by the PP_i analog aminomethylene-diphosphonate. Potassium fluoride, imidodiphosphate, *N,N'*-decyclohexylcarbodi-imide and *N*-ethylmaleimide also inhibited PP_i hydrolysis in the isolated organelles in a dose-dependent manner. These results indicate that the electron-dense vacuoles of *C.reinhardtii* are very similar to acidocalcisomes with regard to their chemical composition and the presence of proton pumps. Polyphosphate was also localized to the contractile vacuole by 4', 6-diamino-2-phenylindole staining, suggesting, with the immunochemical data, a link between these organelles and the acidocalcisomes.

3.217 Characterization of a presenilin-mediated APP carboxyl terminal fragment γ: Evidence for distinct mechanisms involved in "gamma-secretase processing of the APP and notch 1 transmembrane domains

Yu, C et al
J. Biol. Chem.,***276(47)***, *43756-43760 (2001)*

A variety of investigations have led to the conclusion that presenilins (PS) play a critical role in intramembranous, γ-secretase proteolysis of selected type I membrane proteins, including Notch1 and amyloid precursoe protein (APP). We now show that the generation of the S3/Notch intracellular domain and APP-carboxy-terminal fragment γ (CTFγ) derivatives are dependent on PS expression and inhibited by a highly selective and potent γ-secretase inhibitor. Unexpectedly, the APP-CTFγ derivative is generated by processing between Leu645 and Val646 (of APP_{695}), several amino acids carboxyl-terminal to the scissile bonds for production of amyloid β protein peptides. Although the relationship of APP-CTFγ to the production of amyloid β protein peptides is not known, we conclude that in contrast to the highly selective PS-dependent processing of Notch, the PS-dependent γ-secretase processing of APP is largely nonselective, and occurs at multiple sites within the APP transmembrane domain.

3.218 Targeting of Shiga toxin B-subunit to retrograde transport route in association with detergent-resistant membranes

Falguieres, T. et al

*Mol. Biol. Cell, **12**, 2453-2468 (2001)*

In HeLa cells, Shiga toxin B-subunit is transported from the plasma membrane to the endoplasmic reticulum, via early endosomes and the Golgi apparatus, circumventing the late endocytic pathway. We describe here that in cells derived from human monocytes, i.e., macrophages and dendritic cells, the B-subunit was internalized in a receptor-dependent manner, but retrograde transport to the biosynthetic/secretory pathway did not occur and part of the internalized protein was degraded in lysosomes. These differences correlated with the observation that the B-subunit associated with Triton X-100 resistant membranes in HeLa cells, but not in monocyte-derived cells, suggesting that retrograde targeting to the biosynthetic/secretory pathway required association with specialized microdomains of biological membranes. In agreement with this hypothesis we found that in HeLa cells, the B-subunit resisted extraction by Triton X-100 until its arrival in the target compartments of the retrograde pathway, i.e., the Golgi apparatus and the endoplasmic reticulum. Furthermore, destabilization of Triton X-100-resistant membranes by cholesterol extraction potently inhibited B-subunit transport from early endosomes to the *trans*-Golgi network, whereas under the same conditions, recycling of transferrin was not affected. Our data thus provide first evidence for a role of lipid asymmetry in membrane sorting at the interface between early endosomes and the *trans*-Golgi network.

3.219 C-terminal domain of the Epstein-Barr virus LMP2A membrane protein contains a clustering signal

Matskova, L., Ernberg, I., Pawson, T. and Winberg, G.

*J. Virol., **75(22)**, 10941-10949 (2001)*

The latency-regulated transmembrane protein LMP2A interferes with signaling from the B-cell antigen receptor by recruiting the tyrosine kinases Lyn and Syk and by targeting them for degradation by binding the cellular E3 ubiquitin ligase AIP4. It has been hypothesized that this constitutive activity of LMP2A requires clustering in the membrane, but molecular evidence for this has been lacking. In the present study we show that LMP2A coclusters with chimeric rat CD2 transmembrane molecules carrying the 27-amino-acid (aa) intracellular C terminus of LMP2A and that this C-terminal domain fused to the glutathione-S-transferase protein associates with LMP2A in cell lysates. This molecular association requires neither the cysteine-rich region between aa 471 and 480 nor the terminal three aa 495 to 497. We also show that the juxtamembrane cysteine repeats in the LMP2A C terminus are the major targets for palmitoylation but that this acylation is not required for targeting of LMP2A to detergent-insoluble glycolipids-enriched membrane microdomains.

3.220 Agonist-promoted trafficking of human bradykinin receptors: arrestin- and dynamin-independent sequestration of the B_2 receptor and bradykinin in HEK293 cells

Lamb, M.E., de Weerd, W.F.C. and Leeb-Lundberg, L.M.F.

*Biochem. J., **355**, 741-750 (2001)*

In this study, we analyzed the agonist trafficking of human B_2 (B_2R) and B_1 (B_1R) bradykinin (BK) receptors using wild-type and green fluorescent protein (GFP)-tagged receptors in HEKL293 cells. B_2R was sequestered to a major extent upon exposure to BK, as determined by the loss of cell-surface B_2R using radioligand binding and by imaging of B_2R-GFP using laser-scanning confocal fluorescence microscopy. Concurrent BK sequestration was revealed by the appearance of acid-resistant specific BK receptor binding. The same techniques showed that B_1R was sequestered to a considerably lesser extent upon binding of des-Arg^{10}-kallidin. B_2R sequestration was rapid (half-life ~ 5 min) and reached a steady-state level that was significantly lower than that of BK sequestration. B_2R sequestration was minimally inhibited by K44A dynamin (22.4 ± 3.7%), and was insensitive to arrestin- (319-418), which are dominant-negative mutants of dynamin I and β-arrestin respectively. Furthermore, the B_2R-mediated sequestration of BK was completely insensitive to both mutants, as well as the association of BK with a caveolae-enriched fraction of the cells. On the other hand, agonist-promoted sequestration of the β_2-adrenergic receptor was dramatically inhibited by K44A dynamin (81.2 ± 16.3%) and by arrestin- (319-418) (36.9 ± 4.4%). Our results show that B_2R is sequestered to a significantly greater extent than is B_1R upon agonist treatment in HEK293 cells. Furthermore, B_2R appears to be recycled in the process of sequestering BK, and this process occurs in a dynamin- and β-arrestin-independent manner and, at least in part, involves caveolae.

3.221 Subcellular site of superoxide dismutase expression differentially controls AP-1 activity and injury in mouse liver following ischemia/reperfusion

Zhou, W. et al

Hepatology, ***33***, *902-914 (2001)*

Acute damage following ischemia and reperfusion (I/R) in the liver is in part caused by the generation of reactive oxygen species, such as superoxides, during the reperfusion event. Gene therapy directed at attenuating mitochondrial superoxide production following warm I/R injury in the liver has demonstrated great promise in reducing acute hepatocellular damage. In the present study, we have compared the therapeutic effects of ectopic expression of mitochondrial (MnSOD) and cytoplasmic (Cu/ZnSOD) superoxide dismutase using recombinant adenoviral vectors for reducing I/R damage in the liver. Consistent with previous observations, recombinant adenoviral delivery of MnSOD to the liver significantly attenuated both acute liver damage and AP-1 activation following I/R injury to the livers of mice. However, ectopic expression of Cu/ZnSOD diminished neither I/R-induced elevations in serum alanine transaminase (ALT) nor AP-1 activation. Interestingly, baseline activation of AP-1 before I/R-induced injury was seen in livers infected with recombinant Ad.Cu/ZnSOD, but not Ad.MnSOD or Ad.LacZ, vectors. The level of Cu/ZnSOD-induced AP-1 activation was significantly reduced by ablation of Kupffer cells or by coexpression of catalase, suggesting that increased H_2O_2 production facilitated by Cu/ZnSOD in hepatocytes and/or Kupffer cells may be responsible for AP-1 activation. *In vitro* reconstitution studies using hepatocyte and macrophage cell lines demonstrated that Cu/ZnSOD overexpression induces AP-1 in both cell types, and that secretion of a Cu/ZnSOD-induced macrophage factor is capable of elevating AP-1 in hepatocytes. In summary, our findings demonstrate that subcellular sites of superoxide production in the liver can differentially affect the outcome.

3.222 Autophagosome requires specific early Sec proteins for its formation and NSF/SNARE for vacuolar fusion

Ishihara, N. et al

Mol. Biol. Cell, ***12***, *3690-3702 (2001)*

Double membrane structure, autophagosomes, is formed *de novo* in the process of autophagy in the yeast *Saccharomyces cerevisiae*, and many Apg proteins participate in the process. To further understand autophagy, we analyzed the involvement of factors engaged in the secretory pathway. First, we showed that Sec18p (N-ethylmaleimide-sensitive fusion protein, NSF) and Vti1p (soluble N-ethylmaleimide-sensitive fusion protein attachment protein, SNARE), and soluble N-ethylmaleimide-sensitive fusion protein receptor are required for fusion of the autophagosomes to the vacuole but are not involved in autophagosome formation. Second, Sec12p was shown to be essential for autophagy but not for the cytoplasm to vacuole-targeting (Cvt) pathway, which shares mostly the same machinery with autophagy. Subcellular fractionation and electron microscopic analyses showed that Cvt vesicles, but not autophagosomes, can be formed in *sec12* cells. Three other coatmer protein (COPII) mutants, *sec16*, *sec23*, and *sec24*, were also defective in autophagy. The blockage of autophagy in these mutants was not dependent on transport from endoplasmic reticulum-to-Golgi, because mutations in two other COPII genes, *SEC13* and *SEC31*, did not affect autophagy. These results demonstrate the requirement for subgroup of COPII proteins in autophagy. This evidence demonstrating the involvement of Sec proteins in the mechanism of autophagosome formation is crucial for understanding membrane flow during the process.

3.223 ***Yarrowia lipolytica* Pex20p, *Saccharomyces cerevisiae* Pex18p/Pex 21p and mammalian Pex5pL fulfil a common function in the early steps of the peroxisomal PTS2 import pathway**
Einwachter, H., Sowinski, S., Kunau, W-H. and Schliebs, W.
*EMBO Reports, **2(11)**, 1035-1039 (2001)*

Import of peroxisomal matrix proteins is essential for peroxisome biogenesis. Genetic and biochemical studies using a variety of different model systems have led to the discovery of 23 *PEX* genes required for this process. Although it is generally believed that, in contrast to mitochondria and chloroplasts, translocation of proteins into peroxisomes involves a receptor cycle, there are reported differences of an evolutionary conservation of this cycle either with respect to the components or the steps involved in different organisms. We show here that the early steps of protein import into peroxisomes exhibit a greater similarity than was thought previously to be the case. Pex20p of *Yarrowia lipolytica*, Pex18p and Pex21p of *Saccharomyces cerevisiae* and mammalian Pex5pL fulfill a common function in the PTS2 pathway of their respective organisms. These non-orthologous proteins possess a conserved sequence region that most likely represents a common PTS2-receptor binding site and di-aromatic pentapeptide motifs that could be involved in binding of the putative docking proteins. We propose that no necessarily the same proteins but functional modules of them are conserved in the early steps of peroxisomal protein import.

3.224 **Sec6/8 complexes on trans-Golgi network and plasma membrane regulate stages of exocytosis in mammalian cells**
Yeaman, C., Grindstaff, K.K., Wright, J.R. and Nelson, W.J.
*J. Cell Biol., **155(12)**, 593-604 (2001)*

Sec6/8 complex regulates delivery of exocytic vesicles to plasma membrane docking sites, but how it is recruited to specific sites in the exocytic pathway is poorly understood. We identified a Sec6/8 complex on trans-Golgi network (TGN) and plasma membrane in normal rat kidney (NRK) cells that formed either fibroblast- (NRK-49F) or epithelial-like (NRK-52E) intercellular junctions. At both TGN and plasma membrane, Sec6/8 complex colocalizes with exocytic cargo protein, vesicular stomatitis virus G protein (VSVG)-tsO45. Newly synthesized Sec6/8 complex is simultaneously recruited from the cytosol to both sites. However, brefeldin A treatment inhibits recruitment to the plasma membrane and other treatments that block exocytosis (e.g., expression of kinase-inactive protein kinase D and low temperature incubation) cause accumulation of Sec6/8 on the TGN, indicating that steady-state distribution of Sec6/8 complex depends on continuous exocytic vesicle trafficking. Addition of antibodies specific for TGN- or plasma membrane-bound Sec6/8 complexes to semiintact NRK cells results in cargo accumulation in a perinuclear region or near the plasma membrane, respectively. These results indicate that Sec6/8 complex is required for several steps in exocytic transport of vesicles between TGN and plasma membrane.

3.225 **Open reading frame III of Borna disease virus encodes a nonglycosylated matrix protein**
Kraus, I et al
*J. Virol., **75(24)**, 12098-12104 (2001)*

The open reading frame III of Borna virus (BDV) codes for a protein with a mass of 16kDa, named p16 or BDV-M. p16 was described as an N-glycosylated protein in several previous publications and therefore was termed gp18, although the amino acid sequence of p16 does not contain any regular consensus sequence for N glycosylation. We examined glycosylation of p16 and studied its membrane topology using antisera raised against peptides, which comprise the N and the C termini. Neither an N- nor a C-terminal peptide is cleaved from p16 during maturation. Neither deglycosylation of p16 by endoglycosidases nor binding of lectin to p16 was detectable. Introduction of typical N-glycosylation sites at the proposed sites of p16 failed in carbohydrate attachment. Flotation experiments with membranes of BDV-infected cells on density gradients revealed that p16 is not an integral membrane protein, since it can be dissociated from membranes. Our experimental data strongly suggest that p16 is a typical nonglycosylated matrix protein associated at the inner surface of the viral membrane, as is true for homologous protein of other members of the *Mononegavirales* order.

3.226 Association of Na^+ -H^+ exchanger isoform NHE3 and dipeptidyl peptidase IV in the renal proximal tubule

Girardi, A.C.C., Degray, B.C., Nagy, T., Biemesderfer, D. and Aronsen, P.
J. Biol. Chem., ***276(49)***, *46671-46677 (2001)*

In an attempt to identify proteins that assemble with the apical membrane Na^+ -H^+ exchanger isoform NHE3, we generated monoclonal antibodies (mAbs) against affinity-purified NHE3 protein complexes isolated from solubilized renal microvillus membrane vesicles. Hybridomas were selected based on their ability to immunoprecipitate NHE3. We have characterized in detail one of the mAbs (1D11) that specifically co-precipitated NHE3 but not villin or NaPi-2. Western blot analyses of microvillus membranes and immunoelectron microscopy of kidney sections showed that mAb 1D11 recognizes a 110-kDa protein highly expressed on the apical membrane of proximal tubule cells. Immunoaffinity chromatography was used to isolate the antigen against which mAb 1D11 is directed. N-terminal sequencing of the purified protein identified it as dipeptidyl peptidase IV (DPPIV) (EC 3.4.14.15), which was confirmed by assays of DPPIV enzyme activity. We also evaluated the distribution of the NHE3-DPPIV complex in microdomains of rabbit renal brush border. In contrast to the previously described NHE3-megalin complex, which principally resides in a dense membrane population (coated pits) in which NHE3 is active, the NHE3-DPPIV complex was predominantly in the microvillar fraction in which NHE3 is active. Serial precipitation experiments confirmed that anti-megalin and anti-DPPIV antibodies co-precipitate different pools of NHE3. Taken together, these studies revealed an unexpected association of the brush border Na^+ -H^+ exchanger NHE3 with dipeptidyl peptidase IV in the proximal tubule. These findings raise the possibility that association with DP-PIV may affect NHE3 surface expression and/or activity.

3.227 Evidence for coupling of membrane targeting and function of the signal recognition particle (SRP) receptor FtsY

Herskovits, A.A. et al
*EMBO Reports, **2(11),** 1040-1046 (2001)*

Recent studies have indicated that FtsY, the signal recognition particle receptor of *Escherichia coli*, plays a central role in membrane protein biogenesis. For proper function, FtsY must be targeted to the membrane, but its membrane-targeting pathway is unknown. We investigated the relationship between targeting and function of FtsY *in vivo*, by separating its catalytic domain (NG) from its putative targeting domain (A) by three means: expression of split *ftsY*, insertion of various spacers between A and NG, and separation of A and NG by the *in vivo* proteolysis. Proteolytic separation of A and NG does not abolish function, whereas separation by long linkers or expression of split *ftsY* is detrimental. We propose that proteolytic cleavage of FtsY occurs after completion of co-translational targeting and membrane assembly of NG. In contrast, separation by other means may interrupt proper synchronization of co-translational targeting and membrane assembly of NG. The co-translational interaction of FtsY with the membrane was confirmed by *in vitro* experiments.

3.228 Direct evidence for a two-step assembly of apoB48-containing lipoproteins in the lumen of the smooth endoplasmic reticulum of rabbit enterocytes

Cartwright, I.J. and Higgins, J.A.
J. Biol. Chem., ***276(51)***, *48048-48057 (2001)*

The aim of this study was to investigate the types and characteristics of chylomicrons precursor in the lumen of the secretory compartment of rabbit enterocytes. Luminal contents were separated into density subfractions in two continuous self-generating gradients of different density profiles. In enterocytes from rabbits fed a low fat diet, newly synthesized and immunodetectable apoB48 was only in the subfraction of density similar to high density lipoprotein (dense particles); the luminal triacylglycerol (TAG) content was low and only in the subfraction of density similar to that of chylomicrons/very low density lipoproteins (light particles). After feeding fat, newly synthesized and immunodetectable apoB48 was in both dense (phospholipid-rich) and light (TAG-rich) particles. Luminal TAG mass and synthesis increased after fat feeding and was only in light particles. Pulse-chase experiments showed that the luminal-radiolabeled apoB48 lost from the dense particles was recovered in the light particles and the secreted chylomicrons. All of the light particle lipids (mass and newly synthesized) co-immunoprecipitated with apoB48. However, in the dense particles, there was a preferential co-precipitation of the preexisting rather than newly synthesized phospholipid. Assembly of apoB48-containing TAG-enriched lipoproteins is therefore a two-step process. The first step produces dense apoB48 phospholipid-rich particles, which accumulate in

the smooth endoplasmic reticulum lumen. In the second step, these dense particles rapidly acquire the bulk of the TAG and additional phospholipid in a single and rapid step.

3.229 Quantitative and reproducible two-dimensional gel analysis using Phoretix 2D Full
Mahon, P. and Dupree, P.
*Electrophoresis, **22**, 2075-2085 (2001)*

Quantitative two-dimensional polyacrylamide gel electrophoresis (2-D PAGE) is used to determine changes in individual protein levels in complex protein mixtures. To provide reliable data, the software used for 2-D gel image analysis must provide a linear response over a wide dynamic range of data output. Here, we show that Phoretix 2D Full analysis of 2-D gels stained with colloidal Coomassie Brilliant Blue G-250 can provide a linear measure of changes in protein quantity. We show using a complex mixture of *Arabidopsis thaliana proteins*, that this is true for essentially all focused proteins, in a data output range greater than three orders of magnitude. An analysis of the factors that affect errors in the results demonstrated that reproducibility of the data is significantly improved by user seeding, whereas it is reduced by use of the background subfraction algorithms.

3.230 Cvt18/Gsa12 is required for cytoplasm-to-vacuole transport, pexophagy, and autophagy in *Saccharomyces cerevisiae* and *Pichia pastoris*
Guan, J. et al
*Mol. Biol. Cell, **12(12)**, 3821-3838 (2001)*

Eukaryotic cells have the ability to degrade proteins and organelles by selective and nonselective modes of micro- and macroautophagy. In addition, there exist both constitutive and regulated forms of autophagy. For example, pexophagy is a selective process for the regulated degradation of peroxisomes by autophagy. Our studies have shown that the differing pathways of autophagy have many molecular events in common. In this article, we have identified a new member in the family of autophagy genes. *GSA12* in *Pichia pastoris* and its *Saccharomyces cerevisiae* counterpart, *CVT18*, encode a soluble protein with two WD40 domains. We have shown that these proteins are required for pexophagy and autophagy in *P. pastoris* and the Cvt pathway, autophagy, and pexophagy in *S. cerevisiae*. In *P. pastoris*, Gsa12 appears to be required for an early event in pexophagy. That is, the involution of the vacuole or extension of vacuole arms to engulf the peroxisomes does not occur in the *gsa12* mutant. Consistent with its role in vacuole engulfment, we have found that this cytosolic protein is also localized to the vacuole surface. Similarly, Cvt18 displays a subcellular localization that distinguishes it from the characterized proteins required for cytoplasm-to-vacuole delivery pathways.

3.231 Plasma membrane proton ATPase Pma1p requires raft association for surface delivery in yeast
Bagnat, M., Chang, A. and Simons, K.
*Mol. Biol. Cell, **12(12)**, 4129-4138 (2001)*

Correct sorting of proteins is essential to generate and maintain the identity and function of the different cellular compartments. In this study we demonstrate the role of lipid rafts in biosynthetic delivery of Pma1p, the major plasma membrane proton ATPase, to the cell surface. Disruption of rafts led to mistargeting of Pma1p to the vacuole. Conversely, Pma1-7, an ATPase mutant that is mistargeted to the vacuole, was shown to exhibit impaired raft association. One of the previously identified suppressors, multicopy *AST1*, not only restored surface delivery but also raft association of Pma1-7. Ast1p, which is a peripheral membrane protein, was found to directly interact with Pma1p inducing its clustering into a SDS/Triton X100-resistant oligomer. We suggest that clustering facilitates partition of Pma1p into rafts and transport to cell surface.

3.232 Na^+-H^+ exchanger 3 (NHE3) is present in lipid rafts in the rabbit ileal brush border: a role for rafts in trafficking and rapid stimulation of NHE3
Li, X et al
*J. Physiol., **537(2)**, 537-552 (2001)*

Rabbit ileal Na^+-absorbing cell Na^+-H^+ exchanger 3 (NHE3) was shown to exist in three pools in the brush border (BB), including a population in lipid rafts. Approximately 50% of BB NHE3 was associated with Triton X-100-soluble fractions and the other ~50% with Triton X-100-insoluble fractions; ~33% of the detergent-insoluble NHE3 was present in cholesterol-enriched lipid microdomains (rafts).

The raft pool of NHE3 was involved in the stimulation of BB NHE3 activity with epidermal growth factor (EGF). Both EGF and clonidine treatments were associated with a rapid increase in the total amount of BB NHE3. This EGF- and clonidine-induced increase of BB NHE3 was associated with an increase in the raft pool of NHE3 and to a smaller extent with an increase in the total detergent-insoluble fraction, but there was no change in the detergent-soluble pool. In agreement with the rapid increase in the amount of NHE3 in the BB, EGF also caused a rapid stimulation of BB Na^+-H^+ exchange activity.

Disrupting rafts by removal of cholesterol with methyl-β-cyclodextrin (MβCD) or destabilizing the actin cytoskeleton with cytochalasin D decreased the amount of NHE3 in early endosomes isolated by OptiPrep gradient fractionation. Specifically, NHE3 was shown to associate with endosomal vesicles immunoisolated by anti-EEA1 (early endosomal autoantigen 1) antibody-coated magnetic beads and the endosome-associated NHE3 was decreased by cytochalasin D and MβCD treatment.

We conclude that (i) a pool of ileal BB NHE3 exists in lipid rafts; (ii) EGF and clonidine increase the amount of BB NHE3; (iii)lipid rafts and to a lesser extent, the cytoskeleton, but not the detergent-soluble NHE3 pool, are involved in the EGF- and clonidine-induced acute increase in amount of BB NHE3; (iv) lipid rafts and the actin cytoskeleton play important roles in the basal endocytosis of BB NHE3.

3.233 *YFH1*-mediated iron homeostasis is independent of mitochondrial respiration
Chen, O.S. and Kaplan, J.
*FEBS Lett., **509**, 131-134 (2001)*

The human gene frataxin and its yeast homolog *YFH1* affect mitochondrial function. Deficits in frataxin result in Friedreich ataxia, while deletion of *YFH1* results in respiratory incompetence. We determined that as long as respiratory incompetent yeast express Yfh1p they do not accumulate excessive mitochondrial iron. Deletion of *YFH1* in respiratory incompetent yeast results in mitochondrial iron accumulation, while the reintroduction of Yfh1p results in mitochondrial iron export. Further, overexpression of Yfh1p has no effect on oxygen consumption in wild-type yeast grown in either fermentative or respiratory carbon sources. We conclude that the effect of Yfh1p on mitochondrial iron metabolism is independent of respiratory activity.

3.234 Subcellular localization of presenilin 2 endoproteolytic C-terminal fragments
Tekirian, T.L. et al
*Mol. Brain Res., **96**, 14-20 (2001)*

Mutations in the genes that encode the presenilin 1 and 2 (PS1 and PS2) proteins cause the majority of familial Alzheimer's disease (FAD). Differential cleavage of the presenilins results in a generation of at least two C-terminal fragments (CTFs). An increase in the smaller of these two CTFs is one of the few changes in presenilin processing associated with FAD mutations in both PS1 and PS2. Interestingly, the phosphorylation of PS2 modulates the production of the smaller, caspase-derived PS2 CTF, which indicates that the generation of this fragment is a regulated physiologic event. To date, there is no data concerning the subcellular distribution of the caspase-derived PS2 CTF. Because this fragment is normally present at levels that are difficult to detect, we have used cell lines in which the production of wild-type or N141I mutant PS2 is controlled by a tetracycline-regulated promoter in order to assess the subcellular localization of the caspase CTF in relation to the larger, constitutive PS2 CTF and to PS2 holoprotein. We have found that when levels of PS2 are low, the constitutive CTF colocalizes with markers consistent with localization in the early Golgi-ER-Golgi intermediate compartment (ERGIC) while the caspase CTF colocalizes with markers for the endoplasmic reticulum (ER). Following induction of wild-type or mutant PS2, when the levels of PS2 are high, the primary localization of the constitutive CTF appears to shift from the early Golgi-ERGIC in addition to the ER. Interestingly, while the induction of wild-type PS2 resulted in the localization of the caspase CTF primarily in the ER, the induction of mutant PS2 resulted in the localization of the caspase CTF to both the ER and the early Golgi-ERGIC. In summary, these data suggest that the two presenilin 2 CTFs have different patterns of subcellular localization and that the N141I PS2 mutation alters the localization pattern of the PS2 caspase fragment.

3.235 The role of caveolae and caveolin in vesicle-dependent and vesicle-independent trafficking
Matveev, S., Li, X., Everson, W. and Smart, E.J.
*Adv. Drug. Deliver. Rew., **49**, 237-240 (2001)*

Caveolae can mediate endocytosis, transcytosis, and potocytosis. Our understanding of these processes as well as the elucidation of the molecular machinery involved has greatly expanded. In addition, caveolin, a 22 kDa protein often associated with caveolae, can promote the trafficking of sterol through the cytoplasm independent of vesicles. Caveolin also influences the formation, morphology, and function of caveolae. The ability of caveolae and caveolin to mediate macromolecular transport directly impacts a variety of physiological and pathophysiological processes.

3.236 Localization of p24 putative cargo receptors in the early secretory pathway depends on the biosynthetic activity of the cell
Kuiper, R.P. et al
*Biochem. J., **360**, 421-429 (2001)*

Members of the p24 family of putative cargo receptors (subdivided into p24-α, -β, -γ and -δ) are localized in the intermediate- and cis-Golgi compartment of the early secretory pathway, and are thought to play an important role in protein transport. In the present study, we wondered what effect increased biosynthetic cell activity with resulting high levels of protein transport would have on the subcellular localization of p24. We examined p24 localization in *Xenopus* intermediate pituitary melanotrope cells, which in black- and white-adapted animals are biosynthetically highly active and virtually inactive respectively. In addition, p24 localization was studied in *Xenopus* anterior pituitary cells whose activity is not changed during background adaptation. Using organelle fractionation, we found that in the inactive melanotropes and moderately active anterior pituitary cells of white-adapted animals, the p24-α, -β, -γ and -δ proteins are all located in the Golgi compartment. In the highly active melanotropes, but not in the anterior cells of black-adapted animals, the steady-state distribution of all four p24 members changed towards the intermediated compartment and subdomains of the endoplasmic reticulum (ER), most probably the ER exit sites. In the active melanotropes, the major cargo protein pro-opiomelanocortin was mostly localized to ER subdomains and partially co-localized with the p24 proteins. Furthermore, in the active cells, *in vitro* blocking of protein biosynthesis by cycloheximide or dispersion of the Golgi complex by brefeldin A led to a redistribution of the p24 proteins, indicating their involvement in ER-to-Golgi protein transport and extensive cycling in the early secretory pathway. We conclude that the subcellular localization of p24 proteins is dynamic and depends on the biosynthetic activity of the cell.

3.237 Preptin derived from proinsulin-like growth factor II (proIGF-II) is secreted from pancreatic islet β-cells and enhances insulin secretion
Buchanan, C.M., Phillips, A.R. and Cooper, G.J.S.
*Biochem. J., **360**, 431-439 (2001)*

Pancreatic islet β-cells secrete the hormones insulin, amylin and pancreastatin. To search for further β-cell hormones, we purified peptides from secretory granules isolated from cultured murine βTC6-F7 β-cells. We identified a 34 amino-acid peptide (3948 Da), corresponding to Asp^{69}-Leu^{102} of the proinsulin-like growth factor II E-peptide, which we have termed "preptin". Preptin is present in islet β-cells and undergoes glucose-mediated co-secretion with insulin. Synthetic preptin increase insulin secretion from glucose-stimulated βTC6-F7 cells in a concentration-dependent and saturable manner. Preptin infusion into the isolated, perfused rat pancreas increases the second phase of glucose-mediated insulin secretion by 30%, while antipreptin immunoglobulin infusion decreases the first and second phases of insulin secretion by 29 and 26% respectively. These findings suggest that preptin is a physiological amplifier of glucose-mediated insulin secretion.

3.238 Ubiquitin sorts proteins into the intralumenal degradative compartment of the late-endosome/vacuole
Urbanowski, J.L. and Piper, R.C.
*Traffic, **2**, 622-630 (2001)*

Many studies have demonstrated a role for ubiquitin (Ub) in the down-regulation of cell surface proteins. In yeast, down-regulation is marked by the internalization of proteins, followed by their delivery to the lumen of the vacuole where both the cytosolic and lumenal domains are degraded. It is generally believed that the regulatory step of this process is internalization from the plasma membrane and that protein delivery to the lysosome or vacuole is by default. By separating the process of internalization from degradation, we demonstrate that incorporation of proteins into intralumenal vesicles represents a distinct sorting step along the endocytic pathway that is controlled by recognition of ubiquitin. We show that attachment of a single ubiquitin can serve as a specific sorting signal for the degradative pathway by

redirecting recycling Golgi proteins and resident vacuolar proteins into intralumenal vesicles of the yeast vacuole. This pathway is independent of Ptdlns (3,5) P2 and does not rely on the specific composition of transmembrane domain segments. These data provide a physiological basis for how ubiquitination of cell surface proteins guides their degradation and removal from the recycling pathway.

3.239 Membrane protein diffusion sets the speed of rod phototransduction
Calvert, P.D. et al
*Nature, **411**, 90-94 (2001)*

Retinal rods signal the activation of a single receptor molecule by a photon. To ensure efficient photon capture, rods maintain about 10^9 copies of rhodopsin densely packed into membranous disks. But a high packing density of rhodopsin may impede other steps in phototransduction that take place on the disk membrane, by restricting the lateral movement of, and hence the rate of encounters between, the molecules involved. Although it has been suggested that lateral diffusion of proteins on the membrane sets the rate of onset of the photoresponse, it was later argued that the subsequent processing of the complexes was the main determinant of this rate. The effects of protein density on response shut-off have not been reported. Here we show that a roughly 50% reduction in protein crowding achieved by the hemizygous knockout of rhodopsin in transgenic mice accelerates the rising phases and recoveries of flash responses by about 1.7-fold *in vivo*. Thus, in rods the rates of both response onset and recovery are set by the diffusional encounter frequency between proteins on the disk membrane.

3.240 Kinesin-mediated axonal transport of a membrane compartment containing β-secretase and presenilin-1 requires APP
Kamal, A. et al
*Nature, **414**, 643-648 (2001)*

Proteolytic processing of amyloid precursor protein (APP) generates amyloid-β peptide and has been implicated in the pathogenesis of Alzheimer's disease. However, the normal function of APP, whether this function is related to the proteolytic processing of APP, and where this processing takes place in neurons *in vivo* remain unknown. We have previously shown that the axonal transport of APP in neurons is mediated by the direct binding of APP to the kinesin light chain subunit of kinesin-I, a microtubule motor protein. Here we identify an axonal membrane compartment that contains APP, β-secretase and presenilin-1. The fast anterograde axonal transport of this compartment is mediated by APP and kinesin-I. Proteolytic processing of APP can occur in the compartment *in vitro* and *in vivo* in axons. This proteolysis generates amyloid-β and a carboxy-terminal fragment of APP, and liberates kinesin-I from the membrane. These results suggest that APP functions as a kinesin-I membrane receptor, mediating the axonal transport of β-secretase and presenilin-1, and that processing of APP to amyloid-β by secretases can occur in an axonal membrane compartment transported by kinesin-I.

3.241 Acyl-coenzyme A: cholesterol acyltransferase modulates the generation of the amyloid β-peptide
Puglielli, L. et al
*Nature Cell Biol., **3**, 905-912 (2001)*

The pathogenic event common to all forms of Alzheimer’s disease is the abnormal accumulation of the amyloid β-peptide (Aβ). Here we provide strong evidence that intracellular cholesterol compartmentation modulates the generation of Aβ. Using genetic, biochemical and metabolic approaches, we found that cholesteryl-ester levels are directly correlated with Aβ production. Acyl-coenzyme A: cholesterol acyltransferase (ACAT), the enzyme that catalyses the formation of cholesteryl esters, modulates the generation of Aβ through the tight control of the equilibrium between free cholesterol and cholesteryl esters. We also show that pharmacological inhibitors of ACAT, developed for the treatment of atherosclerosis, are potent modulators of Aβ generation, indicating their potential for use in the treatment of Alzheimer’s disease.

3.242 Caspase-3 is localized to endothelial caveolar domains
Oxhorn, B.C., Wadia, R. and Buxton, I.L.O.

3.243 Vesicle Permeabilization by Protofibrillar α-Synuclein: Implications for the Pathogenesis and Treatment of Parkinson's Disease
Volles, M.J. et al
Biochemistry, ***40(26)***, *7812-7819 (2001)*

Fibrillar α-synuclein is a component of the Lewy body, the characteristic neuronal inclusion of the Parkinson's disease (PD) brain. Both α-synuclein mutations linked to autosomal dominant early-onset forms of PD promote the in vitro conversion of the natively unfolded protein into ordered prefibrillar oligomers, suggesting that these protofibrils, rather than the fibril itself, may induce cell death. We report here that protofibrils differ markedly from fibrils with respect to their interactions with synthetic membranes. Protofibrillar α-synuclein, in contrast to the monomeric and the fibrillar forms, binds synthetic vesicles very tightly via a β-sheet-rich structure and transiently permeabilizes these vesicles. The destruction of vesicular membranes by protofibrillar α-synuclein was directly observed by atomic force microscopy. The possibility that the toxicity of α-synuclein fibrillization may derive from an oligomeric intermediate, rather than the fibril, has implications regarding the design of therapeutics for PD.

3.244 The clustered FcγR receptor II is recruited to Lyn-containing membrane domains and undergoes phosphorylation in a cholesterol-dependent manner
Kwiatkowska, K. and Sobota, A.
Eur. J. Immunol., ***31(4)***, *989-998 (2001)*

Phosphorylation of clustered FcγR receptor II (FcγRII) by Src family tyrosine kinases is the earliest event in the receptor signaling cascade. However, the molecular mechanisms for the interaction between FcγRII and these kinases are not elucidated. To asses this problem we isolated high molecular weight complexes of cross-linked FcγRII from non-ionic detergent lysates of U937 monocytic cells. CD55, a glycosylphosphatidylinositol-anchored protein, a ganglioside GM1 and Lyn, a Src family tyrosine kinase, were also located in these complexes. Gradient centrifugation demonstrated that the complexes containing cross-linked FcγRII displayed a low buoyant density. The FcγRII present in the complexes underwent tyrosine phosphorylation. Cross-linked FcγRII and Lyn occupied common 100–200 nm detergent-resistant membrane fragments, as demonstrated by immunoprecipitation and microscopy studies. Pretreatment of the cells with β-cyclodextrin, a cholesterol acceptor, depleted membrane cholesterol and released CD55, GM1 and Lyn from the detergent-resistant complexes. In parallel, the association of Lyn with cross-linked FcγRII was disrupted and phosphorylation of the receptor inhibited. Reincorporation of cholesterol evoked the relocation of Lyn into the detergent-resistant membrane fraction and restored both Lyn association with cross-linked FcγRII and tyrosine phosphorylation of the receptor. Our data demonstrate that cholesterol-enriched membrane rafts can facilitate tyrosine phosphorylation of clustered FcγRII by Lyn kinase.

3.245 The influence of CD40 on the association of the B cell antigen receptor with lipid rafts in mature and immature cells
Malapati, S. and Pierce, S.K.
Eur. J. Immunol., ***31(12)***, *3789-3797 (2001)*

Cholesterol- and sphingolipid-rich membrane microdomains termed lipid rafts appear to play a central role in B cell activation. In mature B cells, signaling through the B cell antigen receptor(BCR) is initiated from within rafts and leads to activation. In immature B cells, the BCR is excluded from rafts and signaling leads to apoptosis. CD40, a member of the tumor necrosis receptor family, is expressed by B cells throughout development and has been shown to influence the results of the engagement of antigen by the BCR in both mature B and immature B cells. Here evidence is provided that CD40 is excluded from the lipid rafts of both mature and immature B cells and remains excluded from rafts even after cross-linking. Nevertheless, in mature B cells CD40 signaling influences the association of the BCR with rafts resulting in an increase in the amount of BCR that translocates into rafts following ligand binding and a subsequent acceleration of the movement of the BCR from rafts. In immature B cells, the cross-linked BCR remains excluded from rafts in the presence of CD40 signaling, conditions under which BCR-induced apoptosis is blocked. These results indicate that CD40 functions outside lipid rafts to influence raft-dependent events in mature B cells and raft-independent events in immature B cells.

3.246 Mechanisms of Aβ Production and Aβ Degradation: Routes to the Treatment of Alzheimer's Disease
Selkoe, D.J., Xia, W., Kimberly, W.T., Vekrellis, K., Walsh, D., Esler, W.P. and Wolfe, M.S:
Alzheimer's Disease: Advances in Ethiology, Pathogenesis and Therapeutics, 421-432 (2001)

In this chapter, we summarize recent work from our laboratories on three interrelated aspects of the role of amyloid β-protein as the initiator of Alzheimer's disease: its production, degradation and aggregation. By analyzing each of these three steps in the economy of Beta-amyloid independently and then attempting to bring together the findings into a unified cycle, we hope to shed light, not only on multiple mechanisms by which Beta-amyloid can accumulate to induce neuronal dysfunction, but also on discrete points of therapeutic intervention.

3.247 Convergence of multiple autophagy and cytoplasm to vacuole components to a perivacuolar membrane compartment prior to *de novo* vesicle formation
Kim, J., Huang, W-P., Stromhaug, P.E. and Klionsky, D.J.
J. Biol. Chem., ***277(1)****, 763-773 (2002)*

Under starvation conditions, the majority of intracellular degradation occurs at the lysosome or vacuole by the autophagy pathway. The cytoplasmic substrates destined for degradation are packaged inside unique double-membrane transport vesicles called autophagosomes and targeted to the lysosome/vacuole for subsequent breakdown and recycling. Genetic analyses of yeast autophagy mutants, *apg* and *aut*, have begun to identify to molecular machinery as well as indicate a substantial overlap with the biosynthetic cytoplasm to vacuole targeting (Cvt) pathway. Transport vesicle formation is a key regulatory step of both pathways. In this study, we characterize the putative compartment from which both autophagosomes and the analogous Cvt vesicles may originate. Microscopy analyses identified a perivacuolar membrane as the resident compartment for both the Apg1-Cvt9 signaling complex, which mediates the switching between autophagic and Cvt transport, and the autophagy/Cvt-specific phosphatidylinositol 3-kinase complex. Further, the perivacuolar compartment designates the initial site of membrane binding by the Apg/Cvt vesicle component Aut7, the Cvt cargo receptor Cvt19, and the Apg conjugation machinery, which functions in the *de novo* formation of vesicles. Biochemical isolation of the vesicle component Aut7 and density gradient analyses recapitulate the microscopy findings while also supporting the paradigm that components required for vesicle formation and packaging concentrate at subdomains within the donor membrane compartment.

3.248 Membrane-bound α-synuclein has a high aggregation propensity and the ability to seed the aggregation of cytosolic form
Lee, H-J., Choi, C. and Lee, S-J.
J. Biol. Chem., ***277(1),*** *671-678 (2002)*

α-Synuclein exists as at least two structural isoforms: a helix-rich, membrane-bound form and a disordered, cytosolic form. Here, we investigated the role of membrane-bound α-synuclein in the aggregation process. In a cell-free system consisting of isolated brain fractions, spontaneous and progressive aggregation of α-synuclein was observed in membranes starting at day 1, whereas no aggregation was observed in the cytosolic fraction in a 3-day period. Addition of antioxidants reduced the aggregation in membrane fraction, implicating the role of oxidative modifications. When excess cytosolic α-synuclein was added to brain membranes, the rate of aggregation was increased while the lag-time was unaffected. Incorporation of cytosolic α-synuclein into membrane-associated aggregates was demonstrated by fractionation and coimmunoprecipitation experiments. In a previous study, we showed that mitochondrial inhibitors such as rotenone, induced α-synuclein aggregation in cells. In the present study using rotenone-treated cells, the earliest appearance of α-synuclein oligomeric species was observed in membranous compartments. Furthermore, α-synuclein-positive inclusions were co-stained with DiI, a membrane-partitioning fluorescent dye, confirming the presence of lipid components in α-synuclein aggregates. These results suggest that membrane-bound α-synuclein can generate nuclei that seed the aggregation of the more abundant cytosolic form.

3.249 Characterization of an acyl-CoA thioesterase that functions as a major regulator of peroxisomal lipid metabolism

Hunt, M.C., Solaas, K., Kase, B.F and Alexon, E.H.
*J. Biol. Chem., **277(2)**, 1128-1138 (2002)*

Peroxisomes function in β-oxidation of very long- and long-chain fatty acids, dicarboxylic fatty acids, bile acid intermediates, prostaglandins, leukotrienes, thromboxanes, pristanic acid and xenobiotic carboxylic acids. These lipids are mainly chain-shortened for excretion as the carboxylic acids are transported to mitochondria for further metabolism. Several of these carboxylic acids are slowly oxidized and may therefore sequester coenzyme A (CoASH). To prevent CoASH sequestration and to facilitate excretion of chain-shortened carboxylic acids, acyl-CoA thioesterases, which catalyze the hydrolysis of acyl-CoA to the free acid and CoASH, may play important roles. We have here cloned and characterized a peroxisomal acyl-CoA thioesterase from mouse, named PTE-2 (peroxisomal acyl-CoA thioesterase 2. PTE-2 is ubiquitously expressed and induced at mRNA level by treatment with the peroxisome proliferator WY-14,643 and fasting. Induction seen by these treatments was dependent on the peroxisome proliferator-activated receptor α. Recombinant PTE-2 showed a broad chain-length specificity with acyl-CoAs from short- and medium-, to long-chain acyl-CoAs, and other substrates including trihydroxycoprostanoyl-CoA, hydroxymethylglutaryl-CoA and branched chain acyl-CoAs, all of which are present in peroxisomes. Highest activities were found with the CoA esters of primary bile acids choloyl-CoA and chenodeoxycholoyl-CoA as substrates. PTE-2 activity is inhibited by free CoASH, suggesting that intraperoxisomal free CoASH levels regulate the activity of this enzyme. The acyl-CoA specificity of recombinant PTE-2 closely resembles that of purified mouse liver peroxisomes, suggesting that PTE-2 is the major acyl-CoA thioesterase in peroxisomes. Addition of recombinant PTE-2 to incubations containing isolated mouse liver peroxisomes strongly inhibited bile acid-CoA: amino acid N-acyltransferase activity, suggesting that this thioesterase can interfere with CoASH-dependent pathways. We propose that PTE-2 functions as a key regulator of peroxisomal lipid metabolism.

3.250 Dynamic association of human insulin receptor with lipid rafts in cells lacking caveolae

Vainio, S. et al
*EMBO Reports, **3(1)**, 1-6 (2002)*

Cholesterol-sphingolipid rich plasma membrane domains, known as rafts, have emerged as important regulators of signal transduction. The adipocytes insulin receptor (IR) is localized to and signals via caveolae that are formed by polymerization of caveolins. Caveolin binds to IR and stimulates signaling. We report that, in liver-derived cells lacking caveolae, autophosphorylation of the endogenous IR is dependent on raft lipids, being compromised by acute cyclodextrin-mediated cholesterol depletion or by antibody clustering of glycosphingolipids. Moreover, we provide evidence that IR becomes recruited to detergent-resistant domains upon ligand binding and that clustering of GM2 ganglioside inhibits IR signaling apparently by excluding the ligand-bound IR from these domains. Our results indicate that, in cells derived from liver, an important insulin target tissue, caveolae are not required for insulin signaling. Rather, the dynamic recruitment of the ligand-bound IR into rafts may serve to regulate interactions in the initiation of the IR signaling cascade.

3.251 Cholesteryl ester is transported from caveolae to internal membranes as part of a caveolin-annexin II lipid-protein

Uittenbogaard, A., Everson, W.V., Matveev, S.V. and Smart, E.J.
J. Biol. Chem., ***277(7)***, *4925-4931 (2002)*

We previously demonstrated that in Chinese hamster ovary cells scavenger receptor, class B, type I-dependent selective cholesteryl ester uptake occurs in caveolae. In the present study we hypothesized that cholesteryl ester is transported from caveolae through the cytosol to an internal membrane by a caveolin chaperon complex similar to the one we originally described for the transport of newly synthesized cholesterol. To test this hypothesis we incubated Chinese hamster ovary cells expressing scavenger receptor, class B, type I with (^{3}H)cholesteryl ester-labeled high density lipoprotein, subfractionated the cells and looked for a cytosolic pool of (^{3}H)cholesteryl ester. The radiolabeled sterol initially appeared in the caveolae fraction, then in the cytosol, and finally in the internal membrane fraction. Caveolin IgG precipitated all of the (^{3}H)cholesteryl ester associated with the cytosol. Co-immunoprecipitation studies demonstrated that in the presence of high density lipoprotein, but not low density lipoprotein or lipoprotein-deficient serum, caveolin IgG precipitated four proteins; annexin II, cyclophilin 40, caveolin, and cyclophilin A. Caveolin acylation-deficient mutants were used to demonstrate that acylation of cysteine 133 but not cysteine 143 or 156 is required for annexin II association with caveolin and the rapid transport of cholesteryl esters out of caveolae. We conclude that a caveolin-annexin II lipid-protein complex facilitates the rapid internalization of cholesteryl esters from caveolae.

3.252 Alzheimer's disease-related overexpression of the cation-dependent mannose-6-phosphate receptor increases Aβ secretion: Role for altered lysosomal hydrolase distribution in β-amyloidogenesis.

Mathews, PM et al
J. Biol. Chem., ***277(7)***, *5299-5307 (2002)*

Prominent endosomal and lysosomal changes are an invariant feature of neurons in sporadic Alzheimer's disease (AD). These changes include increased levels of lysosomal hydrolases in early endosomes and increased expression of the cation-dependent mannose 6-phosphate receptor (CD-MPR), which is partially localized to early endosomes. To determine whether AD-associated redistribution of lysosomal hydrolases resulting from changes in CD-MPR expression affects amyloid precursor protein (APP) processing, we stably transfected APP-overexpressing murine L cells with human CD-MPR. As controls for these cells, we also expressed CD-MPR trafficking-mutants that either localize to the plasma membrane (CD-MPRpm) or to early endosomes (CD-MPRendo). Expression of CD-MPR resulted in a partial redistribution of a representative lysosomal hydrolase, cathepsin D, to early endosomal compartments. Turnover of APP and secretion of sAPPα and sAPPβ were not altered by overexpression of any of the CD-MPR constructs. However, secretion of both human Aβ40 and Aβ42 into the growth media nearly tripled in CD-MPR and CD-MPRendo expressing cells when compared to parental or CD-MPRpm expressing cells. Comparable increases were confirmed for endogenous mouse Aβ40 in L cells expressing these CD-MPR constructs but not overexpressing human APP. These data suggest that redistribution of lysosomal hydrolases to early endocytic compartments mediated by increased expression of the CD-MPR may represent a potentially pathogenic mechanism for accelerating Aβ generation in sporadic AD, where the mechanism of amyloidogenesis is unknown.

3.253 Paxillin associates with poly(A)-binding protein 1 at the dense endoplasmic reticulum and the leading edge of migrating cells

Woods, A.J. et al

J. Biol. Chem., ***277(8)***, *6428-6437 (2002)*

Using mass spectrometry we have identified proteins which co-immunoprecipitate with paxillin, an adaptor protein implicated in the integrin-mediated signaling pathways of cell motility. A major component of paxillin immunoprecipitates was poly(A)-binding protein 1, a 70 kDa mRNA-binding protein. Poly(A)-binding protein 1 associated with both the α and β isoforms of paxillin, and this was unaffected by RNase treatment consistent with a protein-protein interaction. The NH_2-terminal region of paxillin (residues 54-313) associated directly with poly(A)-binding protein 1 in cell lysates, and with His-poly(A)-binding protein 1 immobilized in microtiter wells. Binding was specific, saturable and of high affinity (K_d of ≈ 10nM). Cell fractionation studies showed that at steady state, the bulk of paxillin and poly(A)-binding protein 1 was present in the "dense" polyribosome-associated endoplasmic reticulum. However, inhibition of nuclear export with leptomycin B caused paxillin and poly(A)-binding protein1 to accumulate in the nucleus, indicating that they shuttle between the nuclear and cytoplasmic compartments. When cells migrate, poly(A)-binding protein 1 colocalized with paxillinβ at the tips of lamellipodia. Our results suggest a new mechanism whereby a paxillin-poly(A)-binding protein 1 complex facilitates transport of mRNA from the nucleus to sites of protein synthesis at the endoplasmic reticulum and the leading lamella during cell migration.

3.254 Huntingtin is present in the nucleus, interacts with the transcriptional corepressor C-terminal binding protein, and represses transcription

Kegel, K. et al

J. Biol. Chem., ***277(9)***, *7466-7476 (2002)*

Huntingtin is a protein of unknown function that contains a polyglutamine tract, which is expanded in patients with Huntington's disease (HD). We investigated the localization and a potential function for huntingtin in the nucleus. In human fibroblasts from normal and HD patients, huntingtin localized diffusely in the nucleus and in subnuclear compartments identified as speckles, promyelocytic leukemia protein bodies, and nucleoli. Huntingtin-positive nuclear bodies redistributed after treatment with sodium butyrate. By Western blot, purified nuclei had low levels of full-length huntingtin compared with the cytoplasm but contained high levels of N- and C-terminal huntingtin fragments, which tightly bound the nuclear matrix. Full-length huntingtin co-immunoprecipitated with the transcriptional corepressor C-terminal binding protein, and polyglutamine expansion in huntingtin reduced this interaction. Full-length wild-type and mutant huntingtin repressed transcription when targeted to DNA. Truncated N-terminal mutant huntingtin repressed transcription, whereas the corresponding wild-type fragment did not repress transcription. We speculate that wild-type huntingtin may function in the nuclei in the assembly of nuclear matrix-bound protein complexes involved with transcriptional repression and RNA processing. Proteolysis of mutant huntingtin may alter nuclear functions by disrupting protein complexes and inappropriately repressing transcription in HD.

3.255 ORP2, a homolog of oxysterol binding protein, regulates cellular cholesterol metabolism
Laitinen, S. et al
J. Lipid Res., ***43****, 245-255 (2002)*

Oxysterol binding protein (OSBP) related proteins (ORPs) constitute a family that has at least 12 members in humans. In the present study we characterize one of the novel OSBP homologs, ORP2, which we show to be expressed ubiquitously in mammalian tissues. The ORP2 cDNA encodes a deduced 55 kDa protein that lacks a pleckstrin homology (PH) domain, a feature found in the other family members. Sucrose gradient centrifugation analysis of Chinese hamster ovary (CHO) cell post-nuclear supernatant demonstrated that ORP2 is distributed in soluble and membrane-bound fractions. Immunofluorescence microscopy of the endogenous and overexpressed ORP2 in CHO cells suggested that the membrane-bound fraction of the protein localizes to the Golgi apparatus. Stably transfected CHO cells that overexpress ORP2 showed an increase in [^{14}C]cholesterol efflux to serum, apolipoprotein A-I (apoA-I), and phosphatidyl choline vesicles. The proportion of cellular [^{14}C]cholesterol that is esterified and the ACAT activity measured as [^{14}C]oleyl-CoA conversion into cholesteryl [^{14}C]oleate by the cellular membranes, were markedly decreased in the ORP2 expressing cells. Transient high level overexpression of ORP2 interfered with the clearance of a secretory pathway protein marker from the Golgi complex. The results implicate ORP2 as a novel regulator of cellular sterol homeostasis and intracellular membrane trafficking.

3.256 ARL2 and BART enter mitochondria and bind the adenine nucleotide transporter
Sharer, J.D., Shern, J.S., Van Valkenburg, H., Wallace, D.C., and Kahn, R.A.
Mol. Biol. Cell, ***13****, 71-83 (2002)*

The ADP-ribosylation factor-like 2 (ARL2) GTPase and its binding partner binder of ARL2 (BART) are ubiquitously expressed in rodent and human tissues and are most abundant in brain. Both ARL2 and BART are predominantly cytosolic, but a pool of each was found associated with mitochondria in a protease-resistant form. ARL2 was found to lack covalent N-myristoylation, present on all other members of the ARF family, thereby preserving the N-terminal amphipathic α-helix as a potential mitochondrial import sequence. An overlay assay was developed to identify binding partners for the BART-ARL2-GTP complex and revealed a specific interaction with a protein in bovine brain mitochondria. Purification and partial microsequencing identified the protein as an adenine nucleotide transporter (ANT). The overlay assay was performed on mitochondria isolated from five different tissues from either wild-type or transgenic mice deleted for ANT1. Results confirmed that ANT1 is the predominant binding partner for the BART-ARL2-GTP complex and that the structurally homologous ANT2 protein does not bind the complex. Cardiac and skeletal muscle mitochondria from *ant1*$^{-}$*/ant1*$^{-}$ mice had increased levels of ARL2, relative to that seen in mitochondria from wild-type animals. We conclude that the amount of ARL2 in mitochondria is subject to regulation via an ANT1-sensitive pathway in muscle tissues.

3.257 Acidocalcisomes are functionally linked to the contractile vacuole of *Dictyostelium discoideum*
Marchesini, N., Ruiz, F.A., Vieira, M. and Docampo, R.
J. Biol. Chem., ***277(10)****, 8146-8153 (2002)*

The mass-dense granules of *Dictyostelium discoideum* were shown to contain large amounts of phosphorus, magnesium, and calcium, as determined by x-ray microanalysis, either *in situ* or when purified using **iodixanol** gradient centrifugation. The high phosphorus content was due to the presence of pyrophosphate and polyphosphate, which were also present in the contractile vacuoles. Both organelles also possessed a vacuolar H^+ ATPase, an H^+-pyrophosphatase, and a Ca^{2+}-ATPase, as determined by biochemical methods or by immunofluorescence microscopy. The H^+-pyrophosphatase activity of isolated mass-dense granules was stimulated by potassium ions and inhibited by the pyrophosphate analogs aminomethylene-diphosphonate and imidodiphosphate and by KF and N-ethylmaleimide in a dose-dependent manner. The mass-dense granules and the contractile vacuole appeared to contact each other when the cells were submitted to hyposmotic stress. Acetazolamide inhibited the carbonic anhydrase activity of the contractile vacuoles and prolonged their contraction cycle in a dose-dependent manner. Similar effects were observed with the anion exchanger inhibitor 4,4'-diisothiocyanatodihydrostilbene-2, 2'-disulfonic acid and the vacuolar H^+-ATPase inhibitor bafilomycin A_1. Together, these results suggest that the mass-dense granules of *D. discoideum* are homologous to the acidocalcisomes described in protozoan parasites and are linked to the function of the contractile vacuole.

3.258 Agonist-induced translocation of the kinin B_1 receptor to caveolae-related rafts

Sabourin, T., Bastien, L., Bachvarov, D.R., and Marceau, F.
*Mol. Pharmacol., **61(3),** 546-553 (2002)*

The kallikrein-kinin system, activated during inflammatory conditions and the regulation of specific cardiovascular and renal functions, includes two G protein coupled receptors for bradykinin (BK)-related peptides. The B_1 receptor (B_1R) subtype is not believed to undergo agonist-induced phosphorylation and endocytosis. A conjugate made of the rabbit B_1R fused with the yellow variant of green fluorescent protein (YFP) was expressed in mammalian cells. In COS-1 or human embryonic kidney (HEK) 293 cells, the construction exhibited a nanomolar affinity for the agonist radioligand [^{3}H]Lys-des-Arg^9-BK or the antagonist ligand [^{3}H]Lys-[Leu^8]des-Arg^9-BK and a pharmacological profile virtually identical to that of wild-type B_1R. Lys-des-Arg^9-BK stimulation of HEK 293 cells stably expressing B_1R-YFP but not stimulation of untransfected cells released [^{3}H]arachidonate in a phospholipase A_2 assay. B_1R-YFP was visualized as a continuous labeling of the plasma membranes in stably transfected HEK 293 cells (confocal microscopy). Addition of Lys-des-Arg^9-BK (1-100nM) rapidly concentrated the receptor-associated fluorescence into multiple aggregates that remained associated with the plasma membrane (no significant internalization) and colocalized with caveolin-1. This reaction was slowly reversible upon agonist washing at 37°C and prevented pretreatment with B_1R antagonist. β-Cyclodextrin treatment, which extracts cholesterol from membranes and disrupts caveolae-related rafts, prevented agonist-induced redistribution of B_1R-YFP but not the PLA_2 activation mediated by this receptor. The agonist radioligand copurified with caveolin-1 to a greater extent than the tritiated antagonist in buoyant fractions of HEK 293 cells treated with the ligands. Agonist-induced cellular translocation of the kinin B_1R to caveolae-related rafts without endocytosis is a novel variation on the theme of G-protein-coupled receptor adaptation.

3.259 Conversion of raft associated prion protein to the protease-resistant state requires insertion of PrP-res (PrP^{Sc}) into contiguous membranes

Baron, G.S., Wehrly, K., Dorward, D.W., Chesebro, B., and Caughey, B.
*EMBO J., **21(5)**, 1031-1040 (2002)*

Prion protein (PrP) is usually attached to membranes by a glycosylphosphatidylinositol-anchor that associates with detergent-resistant membranes (DRMs), or rafts. To model the molecular processes that might occur during the initial infection of cells with exogenous transmissible spongiform encephalopathy (TSE) agents, we examined the effect of membrane association on the conversion of the normal protease-sensitive PrP isoform (PrP-sen) to the protease-resistant isoform (PrP-res). A cell-free conversion reaction approximating physiological conditions was used, which contained purified DRMs as a source of PrP-sen and brain microsomes from scrapie-infected mice as a source of PrP-res. Interestingly, DRM-associated PrP-sen was not converted to PrP-res until the PrP-sen was either released from DRMs by treatment with phosphatidylinositol-specific phospholipase C (PI-PLC), or the combined membrane fractions were treated with the membrane-fusing agent polyethylene glycol (PEG). PEG-assisted conversion was optimal at pH 6-7, and acid pretreating the DRMs was not sufficient to permit conversion without PI-PLC or PEG, arguing against late endosomes/lysosomes as primary compartments for PrP conversion. These observations raise the possibility that generation of new PrP-res during TSE infection requires (i) removal of PrP-sen from target cells; (ii) an exchange of membranes between cells; or (iii) insertion of incoming Prp-res into the raft domains of recipient cells.

3.260 Heterologous desensitization of EGF receptors and PDGF receptors by sequestration in caveolae
Matveev, S.V. and Smart, E.J.
*Am. J. Physiol Cell Physiol, **282**, C935-C946 (2002)*

Epidermal growth factor (EGF) and platelet-derived growth factor (PDGF) receptors have been reported to signal via caveolin-containing membranes called caveolae. In contrast, others report that EGF and PDGF receptors are exclusively associated with caveolin-devoid membranes called rafts. Our subcellular fractionation and coimmunoprecipitation studies demonstrate that, in the absence of ligand, EGF and PDGF receptors are associated with rafts. However, in the presence of ligand, EGF and PDGF receptors transiently associate with caveolae. Surprisingly, pretreatment of cells with EGF prevents PDGF-dependent phosphorylation of PDGF receptors and extracellular signal-regulated kinase (ERK) ½ kinase activation. Furthermore, cells pretreated with PDGF prevent EGF-dependent phosphorylation of EGF receptors and ERK1/2 kinase activation. Radioligand binding studies demonstrate that incubation of cells with EGF and PDGF causes both EGF and PDGF receptors to be reversibly sequestered from the extracellular space. Experiments with methyl-β-cyclodextrin, filipin, and antisense caveolin-1 demonstrate that sequestration of the receptors is dependent on cholesterol and caveolin-1. We conclude that ligand-induced stimulation of EGF or PDGF receptors can cause the heterologous desensitization of the other receptor by sequestration in cholesterol-rich, caveolin-containing membranes or caveolae.

3.261 Podocyte slit-diaphragm protein nephrin is linked to the actin cytoskeleton
Yuan, H.Y., Takeuchi, E., and Salant, D.J.
*Am. J. Physiol., Renal Physiol., **282**, F585-F591 (2002)*

Nephrin is an Ig-like transmembrane protein. It is a major component of the podocytes slit diaphragm and is essential for maintaining normal glomular permeability. CD2-associated protein (CD2AP) is also necessary for normal glomerular permeability and is a putative nephrin adaptor molecule. Here, we document that nephrin and CD2AP are linked to the actin cytoskeleton. As detected by Western blot analysis, nephrin and CD2AP were both insoluble when cell membranes from normal rat glomeruli were extracted with 0.5% Triton X-100 (TX-100) at 4°C in the presence of divalent cations, but they were solubilized when the extraction included potassium iodide (KI) to depolymerize F-actin. In addition, a small fraction of the solubilized nephrin and CD2AP was recovered in the low-density fractions of **OptiPrep** flotation gradients, which indicates that a portion of nephrin, possibly associated with CD2AP, resides in a cholesterol- or sphingolipid-rich region of the plasma membrane. Immunofluorescent staining of unfixed sections of normal rat kidney for nephrin, CD2AP, and F-actin was unaltered by treatment with TX-100 but was greatly diminished by addition of KI. Nephrin staining was slightly reduced by cholesterol depletion with methyl-β-cyclodextrin in the presence of TX-100 but was nearly absent after addition of KI. These results document that nephrin anchors the slit diaphragm to the actin cytoskeleton, possibly by linkage to CD2AP, and that nephrin traverses a relatively cholesterol-poor region of the podocytes plasma membrane. In addition, a small pool of actin-associated nephrin and CD2AP resides in lipid rafts, possibly in the cholesterol-rich apical region of the podocytes-foot processes.

3.262 Functional characterization of Δ^3, Δ^2-enoyl-CoA isomerase from rat liver

Zhang, D. et al

J. Biol. Chem., ***277(11)***, *9127-9132 (2002)*

The degradation of unsaturated fatty acids by β-oxidation involves Δ^3, Δ^2-enoyl-CoA isomerase (enoyl-CoA isomerases) that catalyze 3-*cis* → 2-*trans* and 3-*trans* → 2-*trans* isomerizations of enoyl-CoAs and the 2,5 → 3,5 isomerization of dienoyl-CoAs. An analysis of rat liver enoyl-CoA isomerases revealed the presence of a monofunctional enoyl-CoA isomerase (ECI) in addition to mitochondrial enoyl-CoA isomerase (MECI) in mitochondria, whereas peroxisomes contain ECI and multifunctional enzyme 1 (MFE1). Thus ECI, which previously had been described as peroxisomal enoyl-CoA isomerase, was found to be present in both peroxisomes and mitochondria. This enzyme seems to be identical with mitochondrial long-chain enoyl-CoA isomerase (Kilponen, J.M., Palosaari, P.M., and Hiltunen, J.K. 1990 Biochem. J., 269, 223-226). All three hepatic enoyl-CoA isomerases have broad chain length specificities but are distinguishable by their preferences for one of the three isomerization reactions. MECI is most active in catalyzing the 3-*cis* → 2-*trans* isomerization; ECI has a preference for the 3-*trans* → 2- *trans* isomerization, and MFEI is the optimal isomerase for the 2,5 → 3,5 isomerization. A functional characterization based on substrate specificities and total enoyl-CoA isomerase activities in rat liver leads to the conclusion that the 3-*cis* → 2-*trans* and 2,5 → 3,5 isomer-izations in mitochondria are catalyzed overwhelmingly by MECI, whereas ECI contributes significantly to the 3-*trans* → 2-*trans* isomerization. In peroxisomes, ECI is predicted to be the dominant enzyme for the 3-*cis* → 2-*trans* and 3-*trans* → 2-*trans* isomerizations of long-chain intermediates, whereas MFE1 is the key enzyme in the 2,5 → 3,5 isomerization.

3.263 Trafficking and cell surface stability of the epithelial Na^+ channel expressed in epithelial Madin-Darby canine kidney cells

Hanwell, D., Ishikawa, T., Saleki, R., and Rotin, D.

J. Biol. Chem., ***277(12)***, *9772-9779 (2002)*

The apically located epithelial Na^+ channel (αβγ-EnaC) plays a key role in the regulation of salt and fluid transport in the kidney and other epithelia, yet its mode of trafficking to the plasma membrane and its cell surface stability in mammalian cells are poorly understood. Because the expression of EnaC in native tissues/cells is very low, we generated epithelial Madin-Darby canine kidney (MDCK) cells stably expressing αβγ-EnaC, where each subunit is tagged differentially at the intracellular C terminus and the β-subunit is also Myc-tagged at the ectodomain ($\alpha_{HA}\beta_{Myc,T7}\gamma_{FLAG}$). EnaC expression in these cells was verified by immunoblotting with antibodies to the tags, and patch clamp analysis has confirmed that the tagged channel is functional. Moreover, using electron microscopy, we demonstrated apical, but not basal, membrane localization of EnaC in these cells. The glycosylation pattern of the intracellular pool of EnaC revealed peptide N-glycosidase F and endoglycosidase H sensitivity. Surprisingly, the cell surface pool of EnaC, analyzed by surface biotinylation, was also core glycosylated and lacked detectable endoglycosidase H-resistant channels. Extraction of the channel from cells in Triton X-100 demonstrated that both intracellular and cell surface pools of EnaC are largely soluble. Moreover, flotation assays to analyze the presence of EnaC in lipid rafts showed that both intracellular and cell surface pools of this channel are not associated with rafts. We have shown previously that the total cellular pool of EnaC is turned over rapidly ($t_{1/2}$ ~ 1-2 h). Using cycloheximide treatment and surface biotinylation we now demonstrate that the cell surface pool of EnaC has a similarly short half time ($t_{1/2}$ ~ 1 h), unlike the long half-life reported recently for the Xenopus A6 cells. Collectively, these results help elucidate key aspects of EnaC trafficking and turnover rates in mammalian kidney epithelial cells.

3.264 Mannosomes: a molluscan intracellular tubular membrane system related to heavy metal stress
Knigge, T. et al
*Comp. Biochem. and Physiol. Part C, **131**, 259-269 (2002)*

Amongst animals, several hydrogen peroxide-generating oxidases are apparently restricted to molluscs. On of these, D-mannitol oxidase, is concentrated in the alimentary system where it is associated with its own subcellular membrane system of unique tubular morphology, most likely presenting a structural modification of the ER. These structures can be purified by subcellular fractionation and have been termed "mannosomes". Little is known about the functions of mannitol oxidase or of mannosomes, but the previously reported molluscicide-induced increase in mannosomes implies their involvement in a general stress reaction. In this study, we examined the effects of heavy metal stress in the terrestrial gastropod *Arion lusitanicus*. The activity of mannitol oxidase and mannosome abundance were monitored, together with metal effects on heat-shock protein level, and these parameters were compared to heavy metal accumulation in the digestive gland. We found that mannitol oxidase is inhibited by heavy metals more than other oxidases. On the other hand, hsp70 levels and mannosomal protein were increased with enhanced heavy metal stress, the latter indicating a probably increase in the number of mannosome organelles. Thus, stress protein (hsp70) and mannosomal protein were positively correlated with heavy metal accumulation, whereas the enzyme activity showed a negative correlation with increasing heavy metal content of the slugs.

3.265 A proton pumping pyrophosphatase in the Golgi apparatus and plasma membrane vesicles of *Trypanosoma cruzi*
Martinez, R. et al
Mol. & Biochem. Parasitol,, 120, 205-213 (2002)

The proton pumping pyrophosphatase (H^+ -PPase) is an enzyme that has been identified in membranes of plant vacuoles, in the Golgi complex of plants and *Chlamydomonas reinhardii*, and more recently in acidocalcisomes of different trypanosomatids and apicomplexan parasites. Immunofluorescence and immunoelectron microscopy studies using antibodies against the plant enzyme also suggested a plasma membrane localization in different stages of *Trypanosoma cruzi*. In this report we provide immunogold electron microscopy evidence of the presence of the H^+ -PPase in the Golgi complex and plasma membrane of epimastogotes of *T. cruzi*. Pyrophosphate promoted acidification of plasma membrane vesicles as determined using acridine orange. This activity was stimulated by K^+ ions, inhibited by the pyrophosphate analogs imidodiphosphate (IDP) and aminoethylenediphosphate (AMDP) by KF, NaF and DCCD, and it had different responses to ions and inhibitors as compared with the activity present in acidocalcisomes. Surface localization of the H^+ -PPase was confirmed by experiments using biotinylation of cell surface proteins and immunoprecipitation with antibodies against H^+ -PPase. Taken together, these results are consistent with the presence of a functional H^+ -PPase in the plasma membrane of these parasites.

3.266 Alternative splicing unmasks dendritic and axonal targeting signals in metabotropic glutamate receptor 1
Francesconi, A. and Duvoisin, R.M.
*J. Neurosci., **22(6)**, 2196-2205 (2002)*

Precise targeting of neurotransmitter receptors to different neuronal compartments is a fundamental step for the establishment and function of synaptic circuitry. Group I metabotropic glutamate receptors, mGluR1 and mGluR5, control glutamatergic neurotransmission by acting both postsynaptically and presynaptically. Four alternative sliced variants of the mGluR1 gene exist, which differ in their signaling properties and subcellular localization. The present study was undertaken to identify the molecular signals responsible for trafficking of these receptors to different neuronal compartments. Here we report that targeting of mGluR1 to dendrites and axons of transfected retina neurons is controlled by alternative splicing. We have identified in the tail of the receptor a tripeptide motif, which is necessary and sufficient to exclude the splice variant mGluR1b from distal dendrites and to drive it to the axon. This motif, which is present in all the mGluR1 receptors, is masked in mGluR1a by a dominant dendritic signal sequence harbored by the extended C-terminal tail of this splice variant. Furthermore, we show that the identified axonal and dendritic targeting signals are also necessary and sufficient to localize mGluR1b and mGluR1a to the apical and basolateral compartments of Madin-Darby canine kidney cells, respectively, consistent with the existence of common trafficking components for polarized targeting in epithelial cells and neurons.

3.267 Segregation of Bad from lipid rafts is implicated in the induction of apoptosis
Ayllon, V., Fleischer, A., Cayla, X., Garcia, A. and Rebollo, A.
*J. Immunol., **168**, 3387-3393 (2002)*

Many molecules relocate subcellularly in cells undergoing apoptosis. Using coimmunoprecipitation experiments we demonstrate that Bad is not associated to 14-3-3 protein, suggesting a new mechanism for the control of the proapoptotic role of Bad. Here we show, by confocal microscopy and cellular fractionation, that Bad is attached to lipid rafts in IL-4-stimulated cells and thymocytes while associated with mitochondria in IL-4-deprived cells. Disruption of lipid rafts by methyl-β-cyclodextrin treatment induces segregation of Bad from rafts, which correlates with apoptosis. Our results suggest that the interaction of Bad with rafts is a dynamic process regulated by IL-4 and involved in the control of apoptosis.

3.268 Expression of myosin VI within the early endocytic pathway in adult and developing proximal tubules
Biemesderfer, D., Mentone, S.A., Mooseker, M. And Hasson, T.
*Am. J. Physiol., Ren. Physiol**., 282(5)**, F785-F794 (2002)*

Myosin VI is a reverse-direction molecular motor implicated in membrane transport events. Because myosin VI is most highly expressed in the kidney, we investigated its renal localization by using high-resolution immunocytochemical and biochemical methods. Indirect immunofluorescence microscopy revealed myosin VI at the base of the brush border in proximal tubule cells. Horseradish peroxidase uptake studies, which labeled endosomes, and double staining for clathrin adapter protein-2 showed that myosin VI was closely associated with the intermicrovillar (IMV) coated-pit region of the brush border. Localization of myosin VI to the IMV region was confirmed at the electron microscopic level by colloidal gold labeling of ultrathin cryosections. In addition, antigen retrieval demonstrated a small but significant pool of myosin VI on the microvilli. To confirm the association of myosin VI with the IMV compartment, these membranes were separated from other membrane compartments by using 15-25% **OptiPrep** density gradients. Immunoblotting of the gradient fractions confirmed that myosin VI was enriched with markers for the IMV microdomain of the brush border, suggesting that myosin VI associates with proteins in this compartment. Finally, we examined the expression of myosin VI during nephron development. We found myosin VI present in a diffuse cytoplasmic pattern at stage II (S-shaped body phase) and that it was only redistributed fully to the brush border in the stage IV nephron. These studies support a model for myosin VI function in the endocytic process of the proximal tubule.

3.269 Rafts promote assembly and atypical targeting of a nonenveloped virus, rotavirus, in Caco-2 cells
Sapin, C. et al
*J. Virol., **76(9)**, 4591-4602 (2002)*

Rotavirus follows an atypical pathway to the apical membrane of intestinal cells that bypasses the Golgi. The involvement of rafts in this process was explored here. VP4 is the most peripheral protein of the triple-layered structure of this nonenveloped virus. High proportions of VP4 associated with rafts within the cell as early as 3 h postinfection. In the meantime a significant part of VP4 was targeted to the Triton X-100-resistant microdomains of the apical membrane, suggesting that this protein possesses an autonomous signal for its targeting. At a later stage the other structural rotavirus proteins were also found in rafts within the cells together with NSP4, a nonstructural protein required for the final stage of virus assembly. Rafts purified from infected cells were shown to contain infectious particles. Finally purified VP4 and mature virus were shown to interact with cholesterol- and sphingolipid-enriched model lipid membranes that changed their phase preference from inverted hexagonal to lamellar structures. Together these results indicate that a direct interaction of VP4 with rafts promotes assembly and atypical targeting of rotavirus in intestinal cells.

3.270 GCAP1 and rescues rod photoreceptor response in GCAP1/GCAP2 knockout mice
Howes, K.A. et al
The EMBO J., 21(7), 1545-1554 (2002)

Visual transduction in retinal photoreceptors operates through a dynamic interplay of two second messengers, Ca^{2+} and cGMP. Ca^{2+} regulates the activity of guanylate cyclase (GC) and the synthesis of cGMP by acting on a GC-activating protein (GCAP). While this action is critical for rapid termination of the light response, the GCAP responsible has not been identified. To test if GCAP1, one of two GCAPs present in mouse rods, supports the generation of normal flash responses, transgenic mice were generated that express only GCAP1 under the control of the endogenous promoter. Paired flash responses revealed a correlation between the degree of recovery of the rod a-wave and expression levels of GCAP1. In single cell recordings, the majority of the rods generated flash responses that were indistinguishable from wild type. These results demonstrate that GCAP1 at near normal levels supports the generation of wild-type flash responses in the absence of GCAP2.

3.271 Vesicular restriction of synaptobrevin suggests a role for calcium in membrane fusion
Hu, K. et al
*Nature, **415**, 646-650 (2002)*

Release of neurotransmitter occurs when synaptic vesicles fuse with the plasma membrane. This neuronal exocytosis is triggered by calcium and requires three SNARE (soluble-*N*-ethylmaleimide-sensitive factor attachment protein receptors) proteins: synaptobrevin (also known as VAMP) on the synaptic vesicle, and syntaxin and SNAP-25 on the plasma membrane. Neuronal SNARE proteins form a parallel four-helix bundle that is thought to drive the fusion of opposing membranes. As formation of this SNARE complex in solution does not require calcium, it is not clear what function calcium has in triggering SNARE-mediated membrane fusion. We now demonstrate that whereas syntaxin and SNAP-25 in target membranes are freely available for SNARE complex formation, availability of synaptobrevin on synaptic vesicles is very limited. Calcium at micromolar concentrations triggers SNARE complex formation and fusion between synaptic vesicles and reconstituted target membranes. Although calcium does promote interaction of SNARE proteins between opposing membranes, it does not act by releasing synaptobrevin from synaptic vesicle restriction. Rather, our data suggest a mechanism in which calcium-triggered membrane apposition enables syntaxin and SNAP-25 to engage synaptobrevin, leading to membrane fusion.

3.272 Naturally secreted oligomers of amyloid β protein potently inhibit hippocampal long-term potentiation *in vivo*
Walsh, D.M. et al
*Nature, **416**, 535-539 (2002)*

Although extensive data support a central pathogenic role for amyloid β protein (Aβ) in Alzheimer's disease, the amyloid hypothesis remains controversial, in part because a specific neurotoxic species of Aβ and the nature of its effects on synaptic function have not been defined *in vivo*. Here we report that natural oligomers of human Aβ are formed soon after generation of the peptide within specific intracellular vesicles and are subsequently secreted from the cell. Cerebral microinjection of cell medium containing these oligomers and abundant Aβ monomers but no amyloid fibrils markedly inhibited hippocampal long-term potentiation (LTP) in rats *in vivo*. Immunodepletion from the medium of all Aβ species completely abrogated this effect. Pretreatment of the medium with insulin-degrading enzyme, which degrades Aβ monomers but not oligomers, did not prevent the inhibition of LTP. Therefore, Aβ oligomers, in the absence of monomers and amyloid fibrils, disrupted synaptic plasticity *in vivo* at concentrations found in human brain and cerebrospinal fluid. Finally, treatment of cells with γ-secretase inhibitors prevented oligomer formation at doses that allowed appreciable monomer production, and such medium no longer disrupted LTP, indicating that synaptotoxic Aβ oligomers can be targeted therapeutically.

3.273 Polycystin-2 is an intracellular calcium release channel
Koulen, P. et al
*Nature Cell Biol., **4**, 191-197 (2002)*

Polycystin-2, the product of the gene mutated in type 2 autosomal dominant polycystic kidney disease (ADPKD), is the prototypical member of a subfamily of the transient receptor potential (TRP) channel superfamily, which is expressed abundantly in the endoplasmic reticulum (ER) membrane. Here, we show by single channel studies that polycystin-2 behaves as a calcium-activated, high conductance ER channel that is permeable to divalent cations. Epithelial cells overexpressing polycystin-2 show markedly augmented intracellular calcium release signals that are lost after carboxy-terminal truncation or by the introduction of a disease-causing missense mutation. These data suggest that polycystin-2 functions as a calcium –activated intracellular calcium release channel in vivo and that polycystic kidney disease results from the loss of a regulated intracellular calcium release signaling mechanism.

3.274 Specific SHP-2 partitioning in raft domains triggers integrin-mediated signaling via Rho activation
Lacalle, R.A. et al
*J. Cell Biol., **157(2)**, 277-289 (2002)*

Cell signaling does not occur randomly over the cell surface, but is integrated within cholesterol-enriched membrane domains, termed rafts. By targeting SHP-2 to raft domains or to a non-raft plasma membrane fraction, we studied the functional role of rafts in signaling. Serum-depleted, nonattached cells expressing the raft SHP-2 form, but not non-raft SHP-2, display signaling events resembling those observed after fibronectin attachment, such as $ß_1$ integrin clustering, ^{397}Y-FAK phosphorylation, and ERK activation, and also increases Rho-GTP levels. Expression of the dominant negative N19Rho abrogates raft-SHP-2–induced signaling, suggesting that Rho activation is a downstream event in SHP-2 signaling. Expression of a catalytic inactive SHP-2 mutant abrogates the adhesion-induced feedback inhibition of Rho activity, suggesting that SHP-2 contributes to adhesion-induced suppression of Rho activity. Because raft recruitment of SHP-2 occurs physiologically after cell attachment, these results provide a mechanism by which SHP-2 may influence cell adhesion and migration by spatially regulating Rho activity.

3.275 Overexpression of the myelin proteolipid protein leads to accumulation of cholesterol and proteolipid protein in endosomes/lysosomes: implications for Pelizaeus-Merzbacher disease
Simons, M. et al
*J. Cell Biol., **157(2)**, 327-336 (2002)*

Duplications and overexpression of the proteolipid protein (PLP) gene are known to cause the dysmyelinating disorder Pelizaeus-Merzbacher disease (PMD). To understand the cellular response to overexpressed PLP in PMD, we have overexpressed PLP in BHK cells and primary cultures of oligodendrocytes with the Semliki Forest virus expression system. Overexpressed PLP was routed to late endosomes/lysosomes and caused a sequestration of cholesterol in these compartments. Similar results were seen in transgenic mice overexpressing PLP. With time, the endosomal/lysosomal accumulation of cholesterol and PLP led to an increase in the amount of detergent-insoluble cellular cholesterol and PLP. In addition, two fluorescent sphingolipids, BODIPY–lactosylceramide and –galactosylceramide, which under normal conditions are sorted to the Golgi apparatus, were missorted to perinuclear structures. This was also the case for the lipid raft marker glucosylphosphatidylinositol–yellow fluorescence protein, which under normal steady-state conditions is localized on the plasma membrane and to the Golgi complex. Taken together, we show that overexpression of PLP leads to the formation of endosomal/lysosomal accumulations of cholesterol and PLP, accompanied by the mistrafficking of raft components. We propose that these accumulations perturb the process of myelination and impair the viability of oligodendrocytes.

3.276 Platelet-derived growth factor mediates tyrosine phosphorylation of the cytoplasmic domain of the low density lipoprotein receptor-related protein in caveolae
Boucher, P. et al
J. Biol. Chem., ***277(18)***, *15507-15513 (2002)*

The low density lipoprotein (LDL) receptor gene family represents a class of multifunctional, endocytic cell surface receptors. Recently, roles in cellular signaling have also emerged. For instance, the very low density lipoprotein receptor (VLDLR) and the apolipoprotein receptor-2 (apoER2) function in a developmental signaling pathway that regulates the lamination of cortical layers in the brain and involves the activation of tyrosine kinases. Furthermore, the cytoplasmic domain of the LDL receptor-related protein (LRP) was found to be a substrate for the non-receptor tyrosine kinase Src, but the physiological significance of this phosphorylation event remained unknown. Here we show that tyrosine phosphorylation of LRP occurs in caveolae and involves the platelet-derived growth factor (PDGF) receptor β and phosphoinositide 3-kinase. Receptor-associated protein, an antagonist of ligand binding to LRP, and apoE-enriched β-VLDL, a ligand for LRP, reduce PDGF-induced tyrosine phosphorylation of the LRP cytoplasmic domain. In the accompanying paper (Loukinova, E., Ranganathan, S., Kuznetsov, S., Gorlatova, N., Migliorini, M., Ulery, P. G., Mikhailenko, I., Lawrence, D. L., and Strickland, D. K. (2002) *J. Biol. Chem.* 277, 15499-15506) Loukinova *et al*. further demonstrate that one form of PDGF, PDGF-BB, binds specifically to LRP and that phosphorylation of LRP requires the activation of Src family kinases. Taken together, these findings provide a biochemical basis for a cellular signaling pathway that involves apoE and LRP.

3.277 EphrinB phosphorylation and reverse signaling: regulation by Src kinases and PTP-BL phosphatase
Palmer, A. et al
Mol. Cell, ***9***, *725-737 (2002)*

Ephrins are cell surface-associated ligands for Eph receptors and are important regulators of morphogenic processes such as axon guidance and angiogenesis. Transmembrane ephrinB ligands act as “receptor-like” signaling molecules, in part mediated by tyrosine phosphorylation and by engagement with PDZ domain proteins. However, the underlying cell biology and signaling mechanisms are poorly understood. Here we show that Src family kinases (SFKs) are positive regulators of ephrinB phosphorylation and phosphotyrosine-mediated reverse signaling. EphB receptor engagement of ephrinB causes rapid recruitment of SFKs to ephrinB expression domains and transient SFK activation. With delayed kinetics, ephrinB ligands recruit the cytoplasmic PDZ domain containing protein tyrosine phosphatase PTP-BL and are dephosphorylated. Our data suggest the presence of a switch mechanism that allows a shift from phosphotyrosine/SFK-dependent signaling to PDZ-dependent signaling.

3.278 Induction of protein aggregation in an early secretory compartment by elevation of expression level
Schroder, M., Schafer, R. and Friedl, P.
Biotechnol. Bioeng., ***78(2)***, *131-140 (2002)*

A variety of valuable therapeutic proteins are expressed in mammalian cells. Currently, rate-limiting for secretion of recombinant glycoproteins are activities in the secretory pathway of eukaryotic cells, i.e., folding and glycosylation of the naked polypeptide chain. In this paper we provide evidence that elevation of expression level alone is sufficient to cause intracellular aggregation of a structurally relatively simple glycoprotein, antithrombin III (ATIII). Elevation of expression level by selection for increased drug resistance in Chinese hamster ovary cells stably expressing ATIII resulted in formation of disulfide-bonded aggregates of ATIII. Aggregated ATIII displayed incomplete sialylation and Endo H-sensitivity and located to the endoplasmic reticulum and the cis-Golgi compartment in subcellular fractionations. To explore possible causes for aggregation of ATIII at elevated expression levels we investigated the influence of the two major energy sources of cultured mammalian cells, D-glucose and L-glutamine, on the ATIII-yield. We found that utilization of D-glucose was not limiting for synthesis of ATIII at elevated expression levels. However, the amount of ATIII-synthesized per L-glutamine consumed did not seem to increase steadily with expression level for ATIII, indicating that secretion of ATIII may be limited by the capacity of the cell to utilize L-glutamine.

3.279 Presenilin 1 is required for maturation and cell surface accumulation of nicastrin
Leem, J.Y. et al
J. Biol. Chem., 277(21), 19236-19240 (2002)

Proteolytic processing of amyloid precursor protein generates β-amyloid (Aβ) peptides that are deposited in senile plaques in brains of aged individuals and patients with Alzheimer's disease. Presenilins (PS1 and PS2) facilitate the final step in Aβ production, the intramembranous γ-secretase cleavage of amyloid precursor protein. Biochemical and pharmacological evidence support a catalytic or accessory role for PS1 in γ-sec-retase cleavage, as well as a regulatory role in select membrane protein trafficking. In this report, we demon-strate that PS1 is required for maturation and cell surface accumulation of nicastrin, an integral component of the multimeric γ-secretase complex. Using kinetic labeling studies we show that in *PS1*$^{-/-}$ /*PS2*$^{-/-}$ cells nicastrin fails to reach the medial Golgi compartment, and as a consequence, is incompletely glycosylated. Stable expression of human PS1 restores these deficiencies in *PS1*$^{-/-}$ fibroblasts. Moreover, membrane fractionation studies show co-localization of PS1 fragments with mature nicastrin. These results indicate a novel chaperone-type role for PS1 and PS2 in facilitating nicastrin maturation and transport in the early biosynthetic compartments. Our findings are consistent with PS1 influencing γ-secretase processing at multiple steps, including maturation and intracellular trafficking of substrates and component(s) of the γ-secretase complex.

3.280 Distribution of microsomal triglyceride transfer protein within sub-endoplasmic reticulum in human hepatoma cells
Higashi, Y. et al
*Biochim. Biophys. Acta, **1581**, 127-136 (2002)*

Very low-density lipoprotein (VLDL) particles are formed in the endoplasmic reticulum (ER) through the association of lipids with apolipoprotein B (apoB). Microsomal triglyceride transfer protein (MTP), which transfers lipid molecules to nascent apoB, is essential for VLDL formation in ER. However, little is known of the distribution and interaction of MTP with apoB within ER. In this study, distribution patterns of apoB and MTP large subunits (*l*MTP) within ER were examined. Microsomes prepared from HuH-7 cells, a human hepatoma cell line, were further fractionated into rough ER (RER)-enriched subfractions (ER-I fraction) and smooth ER (SER)-enriched subfractions (ER-II fraction) by **iodixanol** density gradient ultracentrifugation. ApoB was evenly distributed in the ER-I and the ER-II fractions, while 1.5 times more *l*MTP molecules were present in the ER-I fraction than in the ER-II fraction. *l*MTP and apoB were coprecipitated both in the ER-I and in the ER-II fractions by immunoprecipitation whenever anti-apoB or an anti-*l*MTP antibody was used. ApoB-containing lipoprotein particles showed a lower density in the ER-II fraction than those in the ER-I fraction. From these results, it is suggested that MTP can function in both rough and smooth regions of ER in human hepatoma cells.

3.281 Molecular determinants of the sensory and motor neuron-derived factor insertion into plasma membrane

Cabedo, H., Luna, C., Fernandez, A.M., Gallar, J. and Ferrer-Montiel, A.
J. Biol. Chem., ***277(22)***, *19905-19912 (2002)*

The sensory and motor neuron-derived factor (SMDF) is a type III neuregulin that regulates development and proliferation of Schwann cells. Although SMDF has been shown to be a type II protein, the molecular determinants of membrane biogenesis, insertion, and topology remain elusive. Here we used heterologous expression of a yellow fluorescent protein-SMDF fusion protein along with a stepwise deletion strategy to show that the apolar/uncharged segment (Ile^{76}-Val^{100}) acts as an internal, uncleaved membrane insertion signal that defines the topology of the protein. Unexpectedly, removal of the transmembrane segment (TM) did not eliminate completely membrane association of C-terminal fragments. TM-deleted fusion proteins, bearing the amino acid segment (Ser^{283}-Glu^{296}) located downstream to the epidermal growth factor-like motif, strongly interacted with plasma membrane fractions. However, synthetic peptides patterned after this segment did not insert into artificial lipid vesicles, suggesting that membrane interaction of the SMDF C terminus may be the result of a post-translational modification. Subcellular localization studies demonstrated that the 40-kDa form, but not the 83-kDa form, of SMDF was segregated into lipid rafts. Deletion of the N-terminal TM did not affect the interaction of the protein with these lipid microdomains. In contrast, association with membrane rafts was abolished completely by truncation of the protein C terminus. Collectively, these findings are consistent with a topological model for SMDF in which the protein associates with the plasma membrane through both the TM and the C-terminal end domains resembling the topology of other type III neuregulins. The TM defines its characteristic type II membrane topology, whereas the C terminus is a newly recognized anchoring motif that determines its compartmentalization into lipid rafts. The differential localization of the 40- and 83-kDa forms of the neuregulin into rafts and non-raft domains implies a central role in the protein biological activity.

3.282 Amyloid-lowering isocoumarins are not direct inhibitors of γ-secretase

Esler, W.P. et al
Nature Cell Biol., ***4***, *E110 (2002)*

The last step in the production of the amyloid-βprotein (Aβ), the major protein component of the cerebral plaques of Alzheimer's disease, is proteolysis within the transmembrane region of the Amyloid-β Precursor Protein (APP) by γ-secretase. The Notch receptor (N) is processed in a similar manner as part of a signalling mechanism essential for metazoan development. Missense mutations in the polytopic presenilins, PS1 and PS2, cause Alzheimer's disease and alter the specificity of γ-secretase to increase production of a much more aggregation-prone form of Aβ. Knockout studies, site-directed mutagenesis, pharmacological profiling, affinity labelling and biochemical isolation all strongly support the hypothesis that γ-secretase is a complex of integral membrane proteins, an aspartyl protease in which the active site resides between the two subunits of a processed form of PS. As a corollary, PS processes both APP and N.

3.283 Identification, characterization, and localization of a novel kidney polycystin-1-polycystin-2 complex

Newby, L.J. et al
J. Biol. Chem., ***277(23)***, *20763-20773 (2002)*

The functions of the two proteins defective in autosomal dominant polycystic kidney disease, polycystin-1 and polycystin-2, have not been fully clarified, but it has been hypothesized that they may heterodimerize to form a "polycystin complex" involved in cell adhesion. In this paper, we demonstrate for the first time the existence of a native polycystin complex in mouse kidney tubular cells transgenic for *PKD1*, non-transgenic kidney cells, and normal adult human kidney. Polycystin-1 is heavily *N*-glycosylated, and several glycosylated forms of polycystin-1 differing in their sensitivity to endoglycosidase H (Endo H) were found; in contrast, native polycystin-2 was fully Endo H-sensitive. Using highly specific antibodies to both proteins, we show that polycystin-2 associates selectively with two species of full-length polycystin-1, one Endo H-sensitive and the other Endo H-resistant; importantly, the latter could be further enriched in plasma membrane fractions and co-immunoprecipitated with polycystin-2. Finally, a subpopulation of this complex co-localized to the lateral cell borders of *PKD1* transgenic kidney cells. These results demonstrate that polycystin-1 and polycystin-2 interact *in vivo* to form a stable heterodimeric complex and suggest that disruption of this complex is likely to be of primary relevance to the pathogenesis of cyst formation in autosomal dominant polycystic kidney disease.

3.284 Ceramide biosynthesis is required for the formation of the oligomeric H^+ -ATPase Pma1p in the yeast endoplasmic reticulum

Lee, M.C., Hamamoto, S. and Schekman, R.

J. Biol. Chem., ***277(25)***, *23395-23401 (2002)*

The yeast plasma membrane H^+-ATPase Pma1p is one of the most abundant proteins to traverse the secretory pathway. Newly synthesized Pma1p exits the endoplasmic reticulum (ER) via COPII-coated vesicles bound for the Golgi. Unlike most secreted proteins, efficient incorporation of Pma1p into COPII vesicles requires the Sec24p homolog Lst1p, suggesting a unique role for Lst1p in ER export. Vesicles formed with mixed Sec24p-Lst1p coats are larger than those with Sec24p alone. Here, we examined the relationship between Pma1p biosynthesis and the requirement for this novel coat subunit. We show that Pma1p forms a large oligomeric complex of >1 MDa in the ER, which is packaged into COPII vesicles. Furthermore, oligomerization of Pma1p is linked to membrane lipid composition; Pma1p is rendered monomeric in cells depleted of ceramide, suggesting that association with lipid rafts may influence oligomerization. Surprisingly, monomeric Pma1p present in ceramide-deficient membranes can be exported from the ER in COPII vesicles in a reaction that is stimulated by Lst1p. We suggest that Lst1p directly conveys Pma1p into a COPII vesicle and that the larger size of mixed Sec24pLst1p COPII vesicles is not essential to the packaging of large oligomeric complexes.

3.285 The epithelial cell cytoskeleton and intracellular trafficking. I. Shiga toxin B-subunit system: retrograde transport, intracellular vectorization, and more

Ludger, J.

Am. J. Physiol. Gastrointest Liver Physiol., ***283***, *G1-G7 (2002)*

Many intracellular transport routes are still little explored. This is particularly true for retrograde transport between the plasma membrane and the endoplasmic reticulum. Shiga toxin B subunit has become a powerful tool to study this pathway, and recent advances on the molecular mechanisms of transport in the retrograde route and on its physiological function(s) are summarized. Furthermore, it is discussed how the study of retrograde transport of Shiga toxin B subunit allows one to design new methods for the intracellular delivery of therapeutic compounds.

3.286 Hypercholesterolemia promotes a CD36-dependent and endothelial nitric oxide synthase mediated vascular dysfunction

Kincer, J.F. et al

J. Biol. Chem., ***277(26)***, *23525-23533 (2002)*

Numerous studies have implicated either the presence or absence of CD36 in the development of hypertension. In addition, hypercholesterolemia is associated with the loss of nitric oxide-induced vasodilation and the subsequent increase in blood pressure. In the current study, we tested the hypothesis that diet-induced hypercholesterolemia promotes the disruption of agonist-stimulated nitric oxide generation and vasodilation in a CD36-dependent manner. To test this, C57BL/6, apoE null, CD36 null, and apoE/CD36 null mice were maintained on chow or high fat diets. In contrast to apoE null mice fed a chow diet, apoE null mice fed a high fat diet did not respond to acetylcholine with a decrease in blood pressure. Caveolae isolated from *in vivo* vessels did not contain endothelial nitric-oxide synthase and were depleted of cholesterol. Age-matched apoE/CD36 null mice fed a chow or high fat diet responded to acetylcholine with a decrease in blood pressure. The mechanism underlying the vascular dysfunction was reversible because vessels isolated from apoE null high fat-fed mice regained responsiveness to acetylcholine wheri incubated with plasma obtained from chow-fed mice. Further analysis demonstrated that the plasma low density lipoprotein fraction was responsible for depleting caveolae of cholesterol, removing endothelial nitric-oxide synthase from caveolae, and preventing nitric oxide production. In addition, the pharmacological removal of caveola cholesterol with cyclodextrin mimicked the effects caused by the low density lipoprotein fraction. We conclude that the ablation of CD36 prevented the negative impact of hypercholesterolemia on agonist-stimulated nitric oxide-mediated vasodilation in apoE null mice. These studies provide a direct link between CD36 and the early events that underlie hypercholesterolemia-mediated hypertension and mechanistic linkages between CD36 function, nitric-oxide synthase activation, caveolae integrity, and blood pressure regulation.

3.287 Construction of a catalytically inactive cholesterol oxidase mutant: inverstigation of the interplay between active site-residues glutamate 361 and histidine 447.
Yin, Y., Liu, P., Anderson, R.G.W. and Sampson, N.S.
*Arch. Biochem. Biophys., **402**, 235-242 (2002)*

Cholesterol oxidase catalyzes the oxidation of cholesterol to cholest-5-en-3-one and its subsequent isomerization into cholest-4-en-3-one. Two active-site residues, His447 and Glu361, are important for catalyzing the oxidation and isomerization reactions, respectively. Double-mutants were constructed to test the interplay between these residues in catalysis. We observed that the k_{cat} of oxidation for the H447Q/E361Q mutant was 3-fold less than that for H447Q and that the k_{cat} of oxidation for the H447E/E361Q mutant was 10-fold slower than that for H447E. Because both doubles-mutants do not have a carboxylate at position 361, they do not catalyze isomerization of the reaction intermediate cholest-5-en-3-one to cholest-4-en-3-one. These results suggest that Glu361 can compensate for the loss of histidine at position 447 by acting as a general base catalyst for oxidation of cholesterol. Importantly, the construction of the double-mutant H447E/E361Q yields an enzyme that is 31,000-fold slower than wild type in k_{cat} for oxidation. The H447E/E361Q mutant is folded like native enzyme and still associates with model membranes. Thus, this mutant may be used to study the effects of membrane binding in the absence of catalytic activity. It is demonstrated that in assays with caveolae membrane fractions, the wild-type enzyme uncouples platelet-derived growth factor receptor β (PDGFRβ) autophosphorylation from tyrosine phosphorylation of neighboring proteins, and the H447E/E361Q mutant does not. Thus maintenance of membrane structure by cholesterol is important for PDGFRβ-mediated signaling. The cholesterol oxidase mutant probe described will be generally useful for investigating the role of membrane structure in signal transduction pathways in addition to the PDGFRβ-dependent pathway tested.

3.288 Optimization of the workup procedure for the analysis of 8-oxo-7, 8-dihydro-2'-deoxyguanosine with electrochemical detection
Hofer, T. and Moller, L.
*Chem. Res. Toxicol., **15**, 426-432 (2002)*

The artifactual generation of the biomarker for oxidative stress, 8-oxo-7,8-dihydro-2'-deoxyguanosine (8-oxodG), during the workup procedure for its analysis is a difficult problem to solve, and the responsible factors are unclear. Here, peroxide removal and other antioxidant procedures during workup were compared using a limited amount of rat liver (50 mg) **as** starting material, with subsequent hydrolysis of 50 μg of DNA. A cold (0°C) high salt GTC (4 M guanidine thiocyanate) non-phenol DNA extraction method was developed where DNA is quickly isolated. GSH (reduced glutathione) generated artifactual formation of 8-oxodG during the workup procedure, whereas H_20_2 removal using catalase, Fe^{3+} removal and passivation using desferal, peroxide removal using glutathione peroxidase, ebselen and a peroxidase mimic lowered the 8-oxodG levels, all identifying peroxides as the responsible oxidants. Desferal was more protective when excluding Mg^{2+} and Ca^{2+} from buffers but was found to disturb the electrochemical detector when repeatedly injected five to six times, even at 100 μM. Addition of the OH• scavenger ethanol in all steps at 2% v/v had no protective effect. Zn^{2+} was found necessary for efficient DNA hydrolysis using nuclease P_1 which was poor below 37°C. Use of water substitutes was tested but inhibited DNA hydrolysis completely. $H_2{}^{18}O$ could, however, work for mass spectrometry methods. Long-term (38 days) storage of 0.5% v/v Triton X-100 generated more 8-oxodG than Tween 20 when Incubated with free dG. The cold GTC DNA extraction method was used for analysis of freshly isolated human lymphocytes/monocytes from 60 healthy men using catalase and TEMPO as antioxidants, giving a background level of 0.074 ± 0.027 8-oxodG/10^5 dG (or 16 8-oxodG/10^8 nucleotides or 1943 8-oxodG/nuclei) which is probably the lowest value obtained yet. No increase with age was seen. Oxidation of dG to 8-oxodG during workup was found to fit a mathematically defined curve, and a calculated background level of 0.047 8-oxodG/10^5 dG was obtained. To obtain more reliable results it is recommended that control samples are included during the workup procedure, having an equal amount of cells (or DNA) as the exposed samples.

3.289 Studying the behavior of mitochondria

Nunnari, J., Wong, E.D., Meesusen, S. and Wagner, J.A.
Methods in Enzymol., ***351***, *381-393 (2002)*

Yeast mitochondria form dynamic tubular structures that are distributed uniformly at the cell cortex and contain an average of 50 to 100 copies of the mitochondrial genome (mtDNA) packaged into higher order nucleoid structures. *Saccharamyces cerevisiae* is an ideal system for studying the mechanisms of both mitochondrial structure and mtDNA maintenance. Even after cells lose mtDNA, often as a secondary consequence of abnormal mitochondrial morphology, they can still be propagated and studied when a fermentable carbon source such as glucose is present. However, because of its role in various metabolic processes, the mitochondrial organelle, even in the absence of mtDNA, is an essential structure that cannot be created de novo. Therefore, a daughter cell survives only if a portion of the mitochondrion is inherited from the mother cell before cytokinesis..
Much insight into the mechanisms that govern the shape, distribution, and movement of mitochondria, as well as the behavior of mtDNA, has been gained through the use of genetic, cytological, and biochemical approaches. This chapter describes some of the cytological and biochemical techniques that have been developed and used in our laboratory and by others in the field to study the behavior of this complex organelle.

3.290 Lipid microdomains are required sites for the selective endocytosis and nuclear translocation of IFN-γ, its receptor chain IFN-γ receptor-1, and phosphorylation and nuclear translocation of STAT1α

Subramanian, P.S. and Johnson, H.M.
J. Immunol, ***169***, *1959-1969 (2002)*

IFN-γ contains a nuclear localization sequence that may play a role in the nuclear transport of activated STAT1α via a complex of IFN-γ/IFN-γ receptor (IFNGR)-1/STAT1α with the nuclear importer nucleoprotein interactor 1. In this study, we examine the mechanism of endocytosis of IFNGR-1 and the relationship of its nuclear translocation to that of STAT1α. In untreated WISH cells, both IFNGR-1 and IFNGR-2 were constitutively localized within caveolae-like microdomains isolated from plasma membrane. However, treatment of cells with IFN-γ resulted in rapid migration of IFNGR-1, but not IFNGR-2, from these microdomains. Filipin pretreatment, which specifically inhibits endocytosis from caveolae-like microdomains, inhibited the nuclear translocation of IFN-γ and IFNGR-1 as well as the tyrosine phosphorylation and nuclear translocation of STAT1α, but did not affect the binding of IFN-γ to these cells. In the Jurkat T lymphocyte cell line, which does not express caveolin-1, nuclear translocation of IFNGR-1 and STAT1α were similarly inhibited by filipin pretreatment. Isolation of lipid microdomains from Jurkat cells showed that both IFNGR-1 and IFNGR-2 were associated with lipid microdomains only after stimulation with IFN-γ, suggesting that the IFNGR subunits are recruited to lipid microdomains by IFN-γ binding in lymphocytes (Jurkat) in contrast to their constitutive presence in epithelial (WISH) cells. In contrast, treatments that block clathrin-dependent endocytosis did not inhibit either activation or nuclear translocation of STAT1α or the nuclear translocation of IFN- or IFNGR-1. Thus, membrane lipid microdomains play an important role in IFN-γ-initiated endocytic events involving IFNGR-1, and the nuclear translocation of IFN-γ, IFNGR-1, and STAT1α

3.291 Second cysteine-rich region of epidermal growth factor receptor contains targeting information for caveolae/rafts

Yamabhai, M. and Anderson, R.G.W.
J. Biol. Chem., ***277(28)***, *24843-24846 (2002)*

Previous studies have shown that ~60% of the epidermal growth factor receptors (EGFRs) in quiescent fibroblasts are concentrated in the caveolae/raft fraction from purified plasma membranes. This high degree of localization suggests the EGFR contains targeting information for lipid domains. We have used mutagenesis to determine that the region of the receptor that controls targeting to caveolae/rafts resides in the juxtamembrane, second cysteine-rich region. A 60-amino acid-long sequence within this region that is continuous with the transmembrane domain was sufficient to target the transmembrane and cytoplasmic tails of both EGFR and the low density lipoprotein receptor to caveolae/rafts. Two *N*-linked sugars in this segment were not required for proper targeting, although unglycosylated wild-type receptors did not localize properly. We conclude that, in contrast to signals for coated pit localization that are in the

cytoplasmic tail, the targeting information for caveolae/rafts is on the extracellular side of the EGFR very close to the membrane.

3.292 Mature glycosylation and trafficking of nicastrin modulate its binding to presenilins
Yang, D-S, et al
J. Biol. Chem., 277(31), 28135-28142 (2002)

Nicastrin is an integral component of the high molecular weight presenilin complexes that control proteolytic processing of the amyloid precursor protein and Notch. We report here that nicastrin is most probably a type 1 transmembrane glycoprotein that is expressed at moderate levels in the brain and in cultured neurons. Immunofluorescence studies demonstrate that nicastrin is localized in the endoplasmic reticulum, Golgi, and a discrete population of vesicles. Glycosidase analyses reveal that endogenous nicastrin undergoes a conventional, trafficking-dependent maturation process. However, when highly expressed in transfected cells, there is a disproportionate accumulation of the endo-β-*N*-acetylglucosaminidase H-sensitive, immature form, with no significant increase in the levels of the fully mature species. Immunoprecipitation revealed that presenilin-1 interacts preferentially with mature nicastrin, suggesting that correct trafficking and co-localization of the presenilin complex components are essential for activity. These findings demonstrate that trafficking and post-translational modifications of nicastrin are tightly regulated processes that accompany the assembly of the active presenilin complexes that execute -secretase cleavage. These results also underscore the caveat that simple overexpression of nicastrin in transfected cells may result in the accumulation of large amounts of the immature protein, which is apparently unable to assemble into the active complexes capable of processing amyloid precursor protein and Notch.

3.293 Blocking of HIV-1 infection by targeting CD4 to nonraft membrane domains
del Real, G. et al
J. Exp. Med., 196(3), 293-301 (2002)

Human immunodeficiency virus (HIV)-1 infection depends on multiple lateral interactions between the viral envelope and host cell receptors. Previous studies have suggested that these interactions are possible because HIV-1 receptors CD4, CXCR4, and CCR5 partition in cholesterol-enriched membrane raft domains. We generated CD4 partitioning mutants by substituting or deleting CD4 transmembrane and cytoplasmic domains and the CD4 ectodomain was unaltered. We report that all CD4 mutants that retain raft partitioning mediate HIV-1 entry and CD4-induced Lck activation independently of their transmembrane and cytoplasmic domains. Conversely, CD4 ectodomain targeting to a nonraft membrane fraction results in a CD4 receptor with severely diminished capacity to mediate Lck activation or HIV-1 entry, although this mutant binds gp120 as well as CD4wt. In addition, the nonraft CD4 mutant inhibits HIV-1 X4 and R5 entry in a $CD4^+$ cell line. These results not only indicate that HIV-1 exploits host membrane raft domains as cell entry sites, but also suggest new strategies for preventing HIV-1 infection.

3.294 Stomatin-related olfactory protein, SRO, spedifically expressed in the murine olfactory sensory neurons
Kobayakawa, K. et al
*J. Neurosci., **22(14)**, 5931-5937 (2002)*

We identified a stomatin-related olfactory protein (SRO) that is specifically expressed in olfactory sensory neurons (OSNs). The mouse *sro* gene encodes a polypeptide of 287 amino acids with a calculated molecular weight of 32 kDa. SRO shares 82% sequence similarity with the murine stomatin, 78% with *Caenorhabditis elegans* MEC-2, and 77% with *C. elegans* UNC-1. Unlike other stomatin-family genes, the *sro* transcript was present only in OSNs of the main olfactory epithelium. No *sro* expression was seen in vomeronasal neurons. SRO was abundant in most apical dendrites of OSNs, including olfactory cilia. Immunoprecipitation revealed that SRO associates with adenylyl cyclase type III and caveolin-1 in the low-density membrane fraction of olfactory cilia. Furthermore, anti-SRO antibodies stimulated cAMP production in fractionated cilia membrane. SRO may play a crucial role in modulating odorant signals in the lipid rafts of olfactory cilia.

3.295 Differential sorting and fate of endocytosedGPI-anchored proteins
Fivaz, M. et al
*EMBO J., **(21/15)**, 3989-4000 (2002)*

In this paper, we studied the fate of endocytosed glycosylphosphatidyl inositol anchored proteins (GPI-APs) in mammalian cells, using aerolysin, a bacterial toxin that binds to the GPI anchor, as a probe. We find that GPI-APs are transported down the endocytic pathway to reducing late endosomes in BHK cells, using biochemical, morphological and functional approaches. We also find that this transport correlates with the association to raft-like membranes and thus that lipid rafts are present in late endosomes (in addition to the Golgi and the plasma membrane). In marked contrast, endocytosed GPI-APs reach the recycling endosome in CHO cells and this transport correlates with a decreased raft association. GPI-APs are, however, diverted from the recycling endosome and routed to late endosomes in CHO cells, when their raft association is increased by clustering seven or less GPI-APs with an aerolysin mutant. We conclude that the different endocytic routes followed by GPI-APs in different cell types depend on the residence time of GPI-APs in lipid rafts, and hence that raft partitioning regulates GPI-APs sorting in the endocytic pathway.

3.296 Akt1 regulates a JNK scaffold during excitotoxic apoptosis
Kim, A.H. et al
*Neuron, **35**, 697-709 (2002)*

Cell survival is determined by a balance among signaling cascades, including those that recruit the Akt and JNK pathways. Here we describe a novel interaction between Akt1 and JNK interacting protein 1 (JIP1), a JNK pathway scaffold. Direct association between Akt1 and JIP1 was observed in primary neurons. Neuronal exposure to an excitotoxic stimulus decreased the Akt1-JIP1 interaction and concomitantly increased association between JIP1 and JNK. Akt1 interaction with JIP1 inhibited JIP1-mediated potentiation of JNK activity by decreasing JIP1 binding to specific JNK pathway kinases. Consistent with this view, neurons from Akt1-deficient mice exhibited higher susceptibility to kainate than wild-type littermates. Overexpression of Akt1 mutants that bind JIP1 reduced excitotoxic apoptosis. These results suggest that Akt1 binding to JIP1 acts as a regulatory gate preventing JNK activation, which is released under conditions of excitotoxic injury.

3.297 Hsp90 interactions and acylation target the G protein $G\alpha_{12}$ but not $G\alpha_{13}$ to lipid rafts
Waheed, A.A. and Jones, T.L.Z.,
*J. Biol. Chem., **277(36)**, 32409-32412 (2002)*

The heterotrimeric G proteins, G_{12} and G_{13}, are closely related in their sequences, signaling partners, and cellular effects such as oncogenic transformation and cytoskeletal reorganization. Yet G_{12} and G_{13} can act through different pathways, bind different proteins, and show opposing actions on some effectors. We investigated the compartmentalization of G_{12} and G_{13} at the membrane because other G proteins reside in lipid rafts, membrane microdomains enriched in cholesterol and sphingolipids. Lipid rafts were isolated after cold, nonionic detergent extraction of cells and gradient centrifugation. $G\alpha_{12}$ was in the lipid raft fractions, whereas $G\alpha_{13}$ was not associated with lipid rafts. Mutation of Cys-11 on $G\alpha_{12}$, which prevents its palmitoylation, partially shifted $G\alpha_{12}$ from the lipid rafts. Geldanamycin treatment, which specifically inhibits Hsp90, caused a partial loss of wild-type $G\alpha_{12}$ and a complete loss of the Cys-11 mutant from the lipid rafts and the appearance of a higher molecular weight form of $G\alpha_{12}$ in the soluble fractions. These results indicate that acylation and Hsp90 interactions localized $G\alpha_{12}$ to lipid rafts. Hsp90 may act as both a scaffold and chaperone to maintain a functional $G\alpha_{12}$ only in discrete membrane domains and thereby explain some of the nonoverlapping functions of $G\alpha_{12}$ and $G\alpha_{13}$ and control of these potent cell regulators.

3.298 Complex N-linked glycosylated nicastrin associates with active γ-secretase and undergoes tight cellular regulation

Taylor Kimberly, W. et al

J. Biol. Chem., 277(38), 35113-35117 (2002)

The intramembranous proteolysis of Notch and the amyloid precursor protein by γ-secretase exemplifies an unusual and newly recognized mechanism of signal transduction in multicellular organisms. Here, we show that only a form of nicastrin (NCT) containing *N*-linked complex oligosaccharides is present in active γ-secretase complexes. Overexpression of NCT does not generate more of this mature protein, a phenomenon analogous to the strictly regulated formation of mature presenilin heterodimers from immature holoprotein. The absence of presenilin severely limits the maturation of NCT, yet combined overexpression of both proteins does not increase respective mature types. Taken together, our findings describe unusual regulatory features of this key signaling protease: the association of NCT with γ-secretase is tightly regulated via glycosylation; at least one other cofactor exists; the least abundant member of the complex becomes limiting; and the cofactor that serves this role may vary by cell type.

3.299 FATS1 channels exogenous FA into 1,2,3-triacyl-sn-glycerol and down-regulates sphingomyelin and cholesterol metabolism in growing 293 cells

Hatch, G.M., Smith, A.J., Xu, F.Y., Hall, A.M. and Bernlohr, D.A.

*J. Lipid. Res., **43**, 1380-1389 (2002)*

Biosynthesis of lipids was investigated in growing 293 cells stably expressing fatty acid (FA) transport protein 1 (FATP1), a bifunctional polypeptide with FA transport as well as fatty acyl-CoA synthetase activity. In short-term (30 s) incubations, FA uptake was increased in FATP1 expressing cells (C8 cells) compared with the vector (as determined by BODIPY 3823 staining and radioactive FA uptake). In long-term (4 h) incubations, incorporation of [^{14}C]acetate, [3H]oleic acid, or [^{14}C]lignoceric acid into 1,2,3-triacyl-*sn*-glycerol (TG) was elevated in C8 cells compared with vector, whereas incorporation of radiolabel into glycerophospholipids was unaltered. The increase in TG biosynthesis correlated with an increase in 1,2-diacyl-*sn*-glycerol acyltransferase activity in C8 cells compared with vector. In contrast, incorporation of [^{14}C]acetate into sphingomyelin (SM) and cholesterol, and [3H]oleic acid or [^{14}C]lignoceric acid into SM was reduced due to a reduction in de novo biosynthesis of these lipids in C8 cells compared with vector. The results indicate that exogenously supplied FAs, and their subsequently produced acyl-CoAs, are preferentially channeled by an FATP1 linked mechanism into the TG biosynthetic pathway and that such internalized lipids down-regulate de novo SM and cholesterol metabolism in actively growing 293 cells.

3.300 Inversin forms a complex with catenins and N-cadherin in polarized epithelial cells

Nürnberger, J., Bacallao, R.L. and Phillips, C.P.

*Mol. Biol. Cell, **13**, 3096-3106 (2002)*

Nephrogenesis starts with the reciprocal induction of two embryonically distinct analages, metanephric mesenchyme and ureteric bud. This complex process requires the refined and coordinated expression of numerous developmental genes, such as *inv*. Mice that are homozygous for a mutation in the *inv* gene (*inv/inv*) develop renal cysts resembling autosomal-recessive polycystic kidney disease. The gene locus containing *inv* has been proposed to serve as a common modifier for some human and rodent polycystic kidney disease phenotypes. We generated polyclonal antibodies to inversin to study its subcellular distribution, potential binding partners, and functional aspects in cultured murine proximal tubule cells. A 125-kDa inversin protein isoform was found at cell-cell junctions. Two inversin isoforms, 140- and 90-kDa, were identified in the nuclear and perinuclear compartments. Plasma membrane allocation of inversin is dependent upon cell-cell contacts and was redistributed when cell adhesion was disrupted after incubation of the cell monolayer with low-calcium/EGTA medium. We further show that the membrane-associated 125-kDa inversin forms a complex with N-cadherin and the catenins. The 90-kDa nuclear inversin complexes with β-catenin. These findings indicate that the *inv* gene product functions in several cellular compartments, including the nucleus and cell-cell adhesion sites.

3.301 Differential localization of the vacuolar H^+ pump with G subunit isoforms (G1 and G2) in mouse neurons

Murata, Y. et al
J. Biol. Chem., ***277(39)***, *36296-36303 (2002)*

Vacuolar H^+-ATPases (V-ATPases), a family of multimeric proton pumps, are involved in a wide variety of physiological processes. We have identified two mouse genes, *Atp6g1* and *Atp6g2*, encoding the *G*1 and *G*2 isoforms of the V-ATPase *G* subunit, respectively. *G*1 was distributed ubiquitously in the tissues examined, whereas *G*2 was specifically distributed in central nervous system neurons. *G*1 was expressed at an early embryonic stage, whereas *G*2 transcription was significantly induced at 10.5 days postcoitus (embryonic day 10.5, *i.e.* 2 days before axon outgrowth). Both *G*1 and *G*2 were strongly expressed in cortical and hippocampal neurons, cerebellar granule cells, and Purkinje cells. Immunohistochemistry with isoform-specific antibodies revealed that *G*2 was localized in cell bodies, dendrites, and axons. In addition, electron microscopy and subcellular fractionation indicated that *G*2 was localized in synaptic vesicles, whereas *G*1 was not detectable. *G*1 and *G*2 exhibit 62% identity, and both isoforms were immunoprecipitated with the *c* and *A* subunits of V-ATPase. *G*2 could complement the yeast deletion mutant Δ*vma10*, which lacks the *G* subunit. The V-ATPases containing the *G*1 and *G*2 isoforms, respectively, showed similar $K_{m(ATP)}$ values and maximal velocity. These results indicate that *G*1 and *G*2 are *bona fide* subunits of V-ATPases and that the enzyme with the *G*2 isoform is involved in synaptic vesicle acidification.

3.302 Myristoylation as a target for inhibiting HIV assembly: Unsaturated fatty acids block viral budding

Lindwasser, O.W. and Resh, M.D.
Proc. Natl. Acad. Sci.,99(20), 13037-13042 (2002)

Modification of HIV-1 Gag with myristic acid, a saturated 14-carbon fatty acid (14:0), is essential for HIV-1 assembly. We recently showed that exogenous treatment of cells with unsaturated 14-carbon fatty acids, 5-*cis*-tetradecenoic acid (14:1*n*-9) and 5-*cis*,8-*cis*-tetradecadienoic acid (14:2*n*-6), reduces the affinity of some myristoylated proteins for plasma membrane rafts, membrane subdomains that have been shown to be required for efficient assembly of HIV. Here we demonstrate that treatment of cells with 14:1*n*-9 and 14:2*n*-6 fatty acids reduced the affinity of Gag for rafts but not membranes in general. Furthermore, treatment of cells with 14-carbon unsaturated fatty acids inhibited Gag-driven particle assembly. These effects most likely reflect covalent modification of Gag with unsaturated fatty acids. Treatment with 14:1*n*-9 and 14:2*n*-6 fatty acids did not alter intracellular protein trafficking, nor did it reduce cell viability. These studies suggest a strategy to attack HIV assembly by selectively altering the patterns of fatty acid modification.

3.303 Elevation of cytochrome P450-immunopositive protein and DNA damage in mussels (*Mytilus edulis*) transplanted to a contaminated site

Shaw, J.P., Large, A.T., Livingstone, D.R., Doyotte, A., Renger, J., Chipman, J.K. and Peters, L.D.
Marine Environ. Res., **54**, 505-509 (2002)

Mytilus edulis were collected from a reference site (Port Quin) and an urban/industrial contaminated site (New Brighton) in the UK during June 1999.Levels of PCBs (Σ7 congeners)
and CB-138 were determined to be, respectively, 21 fold and 16 fold higher in the mussel digestive glands from New Brighton. Levels of CYP1A-immunopositive protein were 1.5 fold higher (P<0.05) at the polluted site but the levels of DNA strand breaks were 1.3 fold higher (P<0.05) at the reference site. Mussels from Port Quin were placed in cages at both sites and both transplanted and indigenous populations sampled in September (13 weeks). Mussels transplanted from the reference site to the industrial site, reported elevated levels of CYP1A-immunopositive protein (1.4 fold; P<0.05) and higher levels of DNA damage (1.2 fold; P<0.05) compared to caged populations at the reference site and a PCB loading similar to the populations from the polluted site.Moreover, transplanted mussels had DNA damage 1.8 fold greater (P<0.05) than indigenous mussels at the transplant site. These changes were small but significant when compared to the observed temporal changes in the indigenous populations.

3.304 Rat liver acyl-CoA synthetase 4 is a peripheral-membrane protein located in two distinct subcellular organelles, peroxisomes and mitochondrial-associated membranes
Lewin T.M., Van Horn, C.G., Krisans, S.K. and Coelman, R.A.
Arch. Biochem. Biophys., **404**, 263-270 (2002)

Obesity and non-insulin-dependent diabetes favor storage of fatty acids in triacylglycerol over oxidation. Recently, individual acyl-CoA synthetase (ACS) isoforms have been implicated in the channeling of fatty acids either toward lipid synthesis or toward oxidation. Although ACS1 had been localized to three different subcellular regions in rat liver, endoplasmic reticulum, mitochondria, and peroxisomes, the study had used an antibody raised against the full-length ACS1 protein which cross-reacts with other isoforms, probably because all ACS family members contain highly conserved amino acid sequences. Therefore, we examined the subcellular location of ACS1, ACS4, and ACS5 in rat liver to determine which isoform was present in peroxisomes, whether the ACSs were intrinsic membrane proteins, and which ACS isoforms were up-regulated by PPARα ligands. Non-cross-reacting ACS1, ACS4, and ACS5 peptide antibodies showed that ACS4 was the only ACS isoform present in peroxisomes isolated from livers of gemfibrozil-treated rats. ACS4 was also present in fractions identified as mitochondria associated membrane (MAM). ACS1 was present in endoplasmic reticulum fractions and ACS5 was present in mitochondrial fractions. Incubation with troglitazone, a specific inhibitor of ACS4, decreased ACS activity in the MAM fractions 30–45% and in the peroxisomal fractions about 30%. Because the signal for ACS4 protein in peroxisomes was so strong compared to the MAM fraction, we examined ACS4 mRNA abundance in livers of rats treated with the PPARα agonist GW9578. Treatment with GW9578 increased ACS4 mRNA abundance 40% and ACS1 mRNA 25%. Although we had originally proposed thatACS4 is linked to triacylglycerol synthesis, it now appears that ACS4 may also be important in activating fatty acids destined for peroxisomal oxidation. We also determined that, unlike ACS1 and 5, ACS4 is not an intrinsic membrane protein. This suggests that ACS4 is probably targeted and linked to MAM and peroxisomes by interactions with other proteins.

3.305 Multicompartmental distribution of tuberous sclerosis gene products, hamartin and tuberin
Yamamoto, Y., Jones, K.A., Mak, B.C., Muehlenbachs, A. and Yeung, R.S.
Arch. Biochem. Biophys., **404**, 210-217 (2002)

Mutations of the TSC1 and TSC2 genes give rise to the clinical disorder of tuberous sclerosis characterized by the development of hamartomas predominantly affecting the central nervous system, kidney, skin, lung, and heart. The function of the gene products, hamartin and tuberin, is not well understood but we have previously suggested a role in vesicular transport. To define the subcellular compartment(s) involved with these two proteins, biochemical characterization of hamartin and tuberin was performed in primary tissues and cell lines. Fractionation of cell lysates identifed both proteins in the cytosolic, microsomal, and cytoskel-etal compartments. In each of these fractions, hamartin and tuberin formed a stable complex in coimmuno-precipitation analyses. Further, they colocalized extensively in discrete, vesicular structures in the cyto-plasm. Within the microsomal compartment, hamartin and tuberin behaved as peripheral membrane proteins that associate with the cytosolic leaflet of membranous domains. Immunoisolation of tuberin-bound vesicles using magnetic beads showed an enrichment of rap1, rab5, and caveolin-1, all of which have been found in specialized lipid microdomains, caveolae. Our data suggest that hamartin and tuberin are multicompart-mental proteins that partially reside in caveolin-1-enriched structures and potentially affect their signaling.

3.306 Sphingolipid and cholesterol dependence of alphavirus membrane fusion
Waarts, B-L., Bittman, R. and Wilschutt, J.
J. Biol. Chem., ***277(41)***, *38141-38147 (2002)*

Semliki Forest virus (SFV) and Sindbis virus (SIN) are enveloped viruses that infect their host cells by receptor-mediated endocytosis and subsequent fusion from within acidic endosomes. Fusion of the viral envelope requires the presence of both cholesterol and sphingolipids in the target membrane. This is suggestive of a possible involvement of sphingolipid-cholesterol microdomains, or "lipid rafts," in the membrane fusion and cell entry process of the virus. In this study, large unilamellar vesicles (LUVs) were prepared from synthetic sphingolipids and sterols that vary with respect to their capacity to promote microdomain formation, as assessed by gradient flotation analysis in the presence of Triton X-100. SFV and SIN fused with LUVs irrespective of the presence or absence of Triton X-100-insoluble microdomains. These results suggest that SFV and SIN do not require the presence of lipid rafts for fusion with target

membranes. Furthermore, it is not necessary for sphingolipids to reside in a detergent-insoluble complex with cholesterol to promote SFV or SIN fusion.

3.307 ER-X: A novel, plasma membrane-associated, putative estrogen receptor that is regulated during development and after ischemic brain injury
Toran-Allerand, C.D. et al
J. Neurosci., 22(19), 8391-8401 (2002)

We showed previously in neocortical explants, derived from developing wild-type and estrogen receptor (ER)-α gene-disrupted (ERKO) mice, that both 17α- and 17β-estradiol elicit the rapid and sustained phosphorylation and activation of the mitogen-activated protein kinase (MAPK) isoforms, the extracellular signal-regulated kinases ERK1 and ERK2. We proposed that the ER mediating activation of the MAPK cascade, a signaling pathway important for cell division, neuronal differentiation, and neuronal survival in the developing brain, is neither ER-α nor ER-β but a novel, plasma membrane-associated, putative ER with unique properties. The data presented here provide further evidence that points strongly to the existence of a high-affinity, saturable, ^{3}H-estradiol binding site (K_d, ~1.6 nM) in the plasma membrane. Unlike neocortical ER-α, which is intranuclear and developmentally regulated, and neocortical ER-β, which is intranuclear and expressed throughout life, this functional, plasma membrane-associated ER, which we have designated "ER-X," is enriched in caveolar-like microdomains (CLMs) of postnatal, but not adult, wild-type and ERKO neocortical and uterine plasma membranes. We show further that ER-X is functionally distinct from ER-α and ER-β, and that, like ER-α, it is re-expressed in the adult brain, after ischemic stroke injury. We also confirmed in a cell-free system that ER-α is an inhibitory regulator of ERK activation, as we showed previously in neocortical cultures. Association with CLM complexes positions ER-X uniquely to interact rapidly with kinases of the MAPK cascade and other signaling pathways, providing a novel mechanism for mediation of the influences of estrogen on neuronal differentiation, survival, and plasticity.

3.308 A novel monoclonal antibody recognizes lysosome-like structures and reflects regional and age-related differences in the rat dentate gyrus
Maeda, S. Et al
Neurosci. Lett., 330, 275-279 (2002)

The granule cells (GCs) of dentate gyrus exhibit regionally specific morphology, and continue to be born and to develop well into adult life. We used a novel monoclonal antibody, MAb2G7, elicited by immunization of a mouse with a microsome fraction of the hippocampus, to evaluate regional and age-related differences in GCs immunohistochemically. Weak cytoplasmic reactions were observed in many neurons, but intense MAb2G7-positive dots were observed only in GCs. Using electron microscopy, we observed that these dots were localized in the internal droplets of secondary lysosome-like structures in GCs. The MAb2G7-positive granules were quantitatively analyzed in young adult and middle-aged rats. Larger numbers of reactive granules were observed in the infrapyramidal blade (IPB) than in the suprapyramidal blade (SPB) and the numbers of positive granules were proportionally reduced in the two areas in middle-aged rats. The changes in the MAb2G7 immunoreactivity may reflect different activation or neurogeneration of GCs in the IPB versus the SPB, and in middle-aged versus young adult rats.

3.309 Nuclear translocation of extracellular superoxide dismutase
Ookawara, T. et al
Biochem. Biophys. Res. Comm., 296, 54-61 (2002)

Histochemical examination of mouse tissues showed nuclear staining of extracellular superoxide dismutase (EC-SOD), and the nuclear translocation of EC-SOD was also confirmed in cultured cells that had been transfected with its gene, as shown by immunohistochemistry and Western blot analysis. The EC-SOD which was secreted into the medium was incorporated into 3T3-L1 cells and a significant fraction of the material taken up was localized in the nucleus. Site-directed mutagenesis indicated that the heparin-binding domain of EC-SOD functions as the nuclear localization signal. These results suggest that the mechanism of the nuclear transport of EC-SOD involves a series of N-terminal signal peptide- and C-terminal heparin-binding domain-dependent processes of secretion, re-uptake and the subsequent nuclear translocation. The findings herein provide support for the view that the role of EC-SOD is to protect the genome DNA from damage by reactive oxygen species and/or the transcriptional regulation of redox-sensitive gene expression.

3.310 Initial steps of *Shigella* infection depend on the cholesterol/shingolipid raft-mediated CD44-IpaB interaction
Lafont, F. Et al
The EMBO J., 21(17), 4449-4457 (2002)

Shigellosis is an acute inflammatory bowel disease caused by the enteroinvasive bacterium *Shigella*. Upon host cell–*Shigella* interaction, major host cell signalling responses are activated. Deciphering the initial molecular events is crucial to understanding the infectious process. We identified a molecular complex involving proteins of both the host, CD44 the hyaluronan receptor, and *Shigella*, the invasin IpaB, which partitions during infection within specialized membrane microdomains enriched in cholesterol and sphingolipids, called rafts. We also document accumulation of cholesterol and raft-associated proteins at *Shigella* entry foci. Moreover, we report that *Shigella* entry is impaired after cholesterol depletion using methyl-ß-cyclodextrin. Finally, we find that *Shigella* is less invasive in sphingosid-based lipid-deficient cell lines, demonstrating the involvement of sphingolipids. Our results show that rafts are implicated in *Shigella* binding and entry, suggesting that raft-associated molecular machineries are engaged in mediating the cell signalling response required for the invasion process.

3.311 Plasma membrane phospholipid scamblase 1 is enriched in lipid rafts and interacts with the epidermal growth factor receptor
Sun, J., Nanjundan, M., Pike, L.J., Wiedmer, T. and Sims, P.J.
Biochemistry, 41, 6338-6345 (2002)

We have identified physical and functional interactions between the epidermal growth factor (EGF) receptor and phospholipid scramblase 1 (PLSCR1), an endofacial plasma membrane protein proposed to affect phospholipid organization. PLSCR1, a palmitoylated protein, was found to partition with the EGF receptor in membrane lipid rafts. Cell stimulation with EGF transiently elevated Tyr-phosphorylation of PLSCR1, peaking at 5 min. Although PLSCR1 is known substrate of c-Ab1 (Sun, J., et al. (2001) *J. Biol. Chem. 276, 28984-28990)*, the Ab1 inhibitor STI571 did not substantially affect its EGF-dependent phosphorylation, suggesting PLSCR1 is a substrate of the EGF receptor kinase, or another EGF-activated kinase. Coinciding with phosphorylation, there was a transient increase in physical association of PLSCR1 with both the EGF receptor and the adapter protein Shc, as determined by immunoprecipitation and Western blotting. Confocal immunofluorescence analysis revealed that EGF initiates rapid internalization of both the EGF receptor and PLSCR1, with trafficking into both distinct and common endosomal pools. These data also suggested that whereas the EGF receptor is ultimately degraded, much of the endocytosed PLSCR1 is recycled to the cell surface with 3 h after EGF treatment. Consistent with this interpretation. Western blotting revealed neither ubiquitination nor proteolysis of PLSCR1 under these conditions, whereas the ubiquitination and degradation of the EGF receptor were rapidly confirmed. Finally, stimulation with EGF was also found to markedly increase the total cellular expression of PLSCR1, suggesting that in addition to its initial interactions with activated EGF receptor, PLSCR1 may also contribute to posttranscriptional effector pathway(s) mediating the cellular response to EGF.

3.312 Truncated soluble Nogo receptor binds Nogo-66 and blocks inhibition of axon growth by myelin
Fournier, A.E., Gould, G.C., Liu, B.P. and Strittmatter, S.M.
*J. Neurosci., **22(20)**, 8876-8883 (2002)*

CNS myelin contains axon outgrowth inhibitors, such as Nogo, that restrict regenerative growth after injury. An understanding of the mechanism of Nogo signaling through its receptor (NgR) is critical to developing strategies for overcoming Nogo-mediated inhibition. Here we analyze the function of NgR domains in outgrowth inhibition. Analysis of alkaline phosphatase (AP)-Nogo binding in COS-7 cells reveals that the leucine-rich repeat domain is necessary and sufficient for Nogo binding and NgR multimerization. Viral infection of embryonic day 7 chick retinal ganglion cells with mutated NgR demonstrates that the NgR C-terminal domain is required for inhibitory signaling but not ligand binding. The NgR glycosylphosphatidylinositol domain is not essential for inhibitory signaling but may facilitate Nogo responses. From this analysis, we have developed a soluble, truncated version of the Nogo receptor that antagonizes outgrowth inhibition on both myelin and Nogo substrates. These data suggest that NgR mediates a significant fraction of myelin inhibition of axon outgrowth.

3.313 Cell surface polarization during yeast mating

Bagnat, M. and Simons, K.

Proc. Natl. Acad. Sci., 99(22), 14283-14188 (2002)

Exposure to mating pheromone in haploid *Saccharomyces cerevisiae* cells results in the arrest of the cell cycle, expression of mating-specific genes, and polarized growth toward the mating partner. Proteins involved in signaling, polarization, cell adhesion, and fusion are localized to the tip of the mating cell (shmoo) where fusion will eventually occur. The mechanisms ensuring the correct targeting and retention of these proteins are poorly understood. Here we show that in pheromone-treated cells, a reorganization of the plasma membrane involving lipid rafts results in the retention of proteins at the tip of the mating projection, segregated from the rest of the membrane. Sphingolipid and ergosterol biosynthetic mutants fail to polarize proteins to the tip of the shmoo and are deficient in mating. Our results show that membrane microdomain clustering at the mating projection is involved in the generation and maintenance of polarity during mating.

3.314 RNA incorporation is critical for retroviral particle integrity after cell membrane assembly of Gag complexes

Wang, S-W. and Aldovini, A.

J. Virol., 76(23), 11853-11865 (2002)

The nucleocapsid (NC) domain of retroviruses plays a critical role in specific viral RNA packaging and virus assembly. RNA is thought to facilitate viral particle assembly, but the results described here with NC mutants indicate that it also plays a critical role in particle integrity. We investigated the assembly and integrity of particles produced by the human immunodeficiency virus type 1 M1-2/BR mutant virus, in which 10 of the 13 positive residues of NC have been replaced with alanines and incorporation of viral genomic RNA is virtually abolished. We found that the mutations in the basic residues of NC did not disrupt Gag assembly at the cell membrane. The mutant Gag protein can assemble efficiently at the cell membrane, and viral proteins are detected outside the cell as efficiently as they are for the wild type. However, only ~10% of the Gag molecules present in the supernatant of this mutant sediment at the correct density for a retro-viral particle. The reduction of positive charge in the NC basic domain of the M1-2/BR virus adversely affects both the specific and nonspecific RNA binding properties of NC, and thus the assembled Gag poly-protein does not bind significant amounts of viral or cellular RNA. We found a direct correlation between the % of Gag associated with sedimented particles and the amount of incorporated RNA. We con-clude that RNA binding by Gag, whether the RNA is viral or not, is critical to retroviral particle integrity after cell membrane assembly and is less important for Gag-Gag interactions during particle assembly and release.

3.315 Proteomic analysis of a detergent-resistant membrane skeleton from neutrophil plasma membranes

Nebl, T. et al

J. Biol. Chem., 277(45), 43999-43409 (2002)

Plasma membranes are organized into functional domains both by liquid-ordered packing into "lipid rafts," structures that resist Triton extraction, and by attachments to underlying cytoskeletal proteins in assemblies called "membrane skeletons." Although the actin cytoskeleton is implicated in many lipid raft-mediated signaling processes, little is known about the biochemical basis for actin involvement. We show here that a subset of plasma membrane skeleton proteins from bovine neutrophils co-isolates with cholesterol-rich, detergent-resistant membrane fragments (DRMs) that exhibit a relatively high buoyant density in sucrose (DRM-H; *d* ~1.16 g/ml). By using matrix-assisted laser desorption/ionization time of flight and tandem mass spectrometry, we identified 19 major DRM-H proteins. Membrane skeleton proteins include fodrin (nonerythroid spectrin), myosin-IIA, myosin-IG, α-actinin 1, α-actinin 4, vimentin, and the F-actin-binding protein, supervillin. Other DRM-H components include lipid raft-associated integral membrane proteins (stomatin, flotillin 1, and flotillin 2), extracellular surface-bound and glycophosphatidylinositol-anchored proteins (IgM, membrane-type 6 matrix metalloproteinase), and intracellular dually acylated signaling proteins (Lyn kinase, $G\alpha_{i-2}$). Consistent with cytoskeletal association, most DRM-H-associated flotillin 2, Lyn, and $G\alpha_{i-2}$ also resist extraction with 0.1 M octyl glucoside. Supervillin, myosin-IG, and myosin-IIA resist extraction with 0.1 M sodium carbonate, a treatment that removes all detectable actin, suggesting that these cytoskeletal proteins are proximal to the DRM-H bilayer. Binding of supervillin to the DRM-H fragments is confirmed by co-immunoaffinity purification. In spreading neutrophils, supervillin localizes with F-actin in cell extensions and in discrete basal puncta that partially overlap with $G\alpha_i$ staining. We

suggest that the DRM-H fraction represents a membrane skeleton-associated subset of leukocyte signaling domains.

3.316 Presence of detergent-resistant microdomains in lysosomal membranes
Taute, A. et al
Biochem. Biophys. Res. Comm., ***298(3)***, *5-9 (2002)*

We examined the association of acetyl-CoA:α -glucosaminide *N*-acetyltransferase, a lysosomal enzyme participating in the degradation of heparan sulfate with other components of the lysosomal membrane. We prepared lysosomal membranes from human placenta and treated them with zwitterionic and non-ionic detergents. Membrane proteins were solubilized either in the presence of CHAPS at room temperature or of Triton X-100 at 4 °C. The CHAPS-containing extract was subjected to gel filtration in a column with the nominal size exclusion of 0.6 MDa. Under these conditions the enzyme fractionated near the void volume. To examine the association of the enzyme with detergent-resistant lipid microdomains, the extract that had been prepared with Triton X-100 was subjected to flotation in a density gradient medium. After centrifug-ation, a major portion of the activity of the acetyltransferase was found at the top of the gradient along with the bulk of alkaline phosphatase. Alkaline phosphatase is a glycosylphosphatidylinositol-anchored protein; possibly a contaminant in the lysosomal fraction originating from the plasma membrane and adventitiously an internal control for the flotation in the gradient. In contrast, acetyltransferase is a genuine lysosomal protein that obligatorily spans the membrane since it transfers acetyl residues from acetyl-CoA in cytosol to glucosaminyl residues in heparan sulfate fragments in the lysosomal matrix. To our knowledge this is the first report on association of a lysosomal membrane protein with detergent-resistant membrane microdomains or rafts.

3.317 A specific binding protein/receptor for 1α,25-dihydroxyvitamin D_3 is present in an intestinal caveolae membrane fraction
Norman, A.W., Olivera, C.J., Silva, F.R.M.B. and Bishop, J.E.
Biochem. Biophys. Res. Comm., ***298(3)***, *414-419 (2002)*

The steroid hormone 1α,25-dihydroxyvitamin D_3 [1α,25$(OH)_2D_3$] produces biological responses by interaction with both a well-characterized nuclear receptor (VDR_{nuc}) to regulate gene transcription and with an as-yet uncharacterized membrane-associated protein/receptor (VDR_{mem}) to generate a variety of rapid, non-genotropic responses. We report for the first time that [^{3}H]1α,25$(OH)_2D_3$ binds with high affinity to a chick duodenal caveolae-enriched membrane fraction (CMF) isolated without the use of detergents. Caveolae are plasma membrane invaginations implicated in signal transduction and molecular transport processes. Using the CMF fraction as a possible source of VDR_{mem}, we found that the in vitro binding of [^{3}H]1α,25$(OH)_2D_3$ was ligand dependent and saturable; the K_D and B_{max} were 1.3±0.6 nM and 29±11 fmol 1,25$(OH)_2D_3$/mg protein (n=17), respectively. Immunoblot analysis of the CMF confirms the presence of caveolin-1, a marker protein for membranes with caveolae. Therefore, chick CMF may represent a good source for isolation and characterization of the putative VDR_{mem} for 1α,25$(OH)_2D_3$.

3.318 Novel non-labile covalent binding of sulfamethoxazole reactive metabolites to cultured human lymphoid cells

Summan, M. and Cribb, A.E.

Chemico-Biol. Interactions, 142, 155-173 (2002)

Sulfamethoxazole (SMX) causes rare hypersensitivity syndrome reactions characterized by fever and multi-organ toxicity. Covalent binding of SMX reactive metabolites to cellular proteins has been demonstrated but the link between cytotoxicity and targets of covalent binding has not been explored. We therefore invest-igated the relationship between covalent binding of the reactive SMX-hydroxylamine (SMX-HA) metabo-lite, and its cytotoxicity to a hystiocytic lymphoma (U937) cell line. Incubation of U937 cells with 0–1 mM SMX-HA for 3 h resulted in dose-dependent cytotoxicity, as assessed by tetrazolium dye conversion at 24 h. SMX-HA caused dose-dependent covalent binding to cellular proteins as assessed by immunoblotting with SMX antisera at 3 and 24 h. Covalent binding was predominantly to proteins of approximately 45, 59 and 75 kDa, but other targets were also observed. The relative extent of binding to proteins was significantly different from the relative cytotoxicity at 24 h. Further, cells surviving at 24 h also had extensive covalent binding. Covalent binding was observed under reducing (β-mercaptoethanol) and non-reducing conditions to plasma membrane and microsomal but not cytosolic proteins. This non-labile covalent binding has not been previously reported. These observations suggest that extensive covalent binding does not necessarily lead to cell death, allowing the accumulation of potentially immunogenic drug-protein conjugates. These observations in whole cells may be relevant to the immunopathogenesis of SMX hypersensitivity syndrome reactions.

3.319 Molecular mechanism for orienting membrane and actin dynamics to nascent cell-cell contacts in epithelial cells

Hansen, M.D., Ehrlich, J.S. and Nelson, W.J.

J. Biol. Chem., 277(47), 45371-45376 (2002)

The small GTPase Rac1 has been implicated in regulation of cell migration and cell-cell adhesion in epithelial cells. Little is known, however, about the spatial and temporal coordination of Rac1 activity required to balance these competing processes. We fractionated endogenous Rac1-containing protein complexes from membranes of Madin-Darby canine kidney cells and identified three major complexes comprising a Rac1·PAK (p21-activated kinase) complex, and 11 S and 16 S Rac1 complexes. Significantly, Rac1 shifts from the 11 S to a 16 S particle during initiation of cell-cell adhesion. This shift may reflect a diffusion trapping mechanism by which these Rac1 complexes are localized to cadherin-mediated cell-cell contacts through an interaction with annexin II.

3.320 Regulated expression and intracellular localization of cystatin F in human U937 cells
Nathanson, C-M, Wasselius, J., Wallin, H. and Abrahamson, M.
*Eur. J. Biochem., **269**, 5502-5511 (2002)*

Cystatin F is a cysteine peptidase inhibitor recently discovered in haematopoietic cells by cDNA cloning. To further investigate the expression, distribution and properties of the native human inhibitor the promyeloid cell line U937 has been studied. The cells expressed relatively large quantities of cystatin F, which was found both secreted and intracellularly. The intracellular levels were unusually high for a secreted cystatin (≈25% of the cystatin F in 2- or 4-day culture medium). By contrast, U937 cells contained only 3–4% of the related inhibitor, cystatin C. Cystatin F purified from lysates of U937 cells showed three major forms carrying two, one or no carbohydrate chains. Immunocytochemistry demonstrated a marked cytoplasmic cystatin F staining in a granular pattern. Double staining with a marker for endoplasmic reticulum revealed no colocal-ization for cystatin F. Analysis of the promoter region of the cystatin F gene (*CST7*) showed that it, like that of the cystatin C gene (*CST3*), is devoid of typical TATA- and CAAT-box elements. In contrast to the cyst-atin C promoter, it does not contain multiple Sp1 binding sites, but has a unique site for C/EBPα, possibly explaining the restricted expression of the cystatin F gene. Cells stimulated with all-*trans* retinoic acid to differentiate them towards a granulocytic pathway, showed a strong (≈18-fold) down-regulation of intra-cellular cystatin F and almost abolished secreted levels of the inhibitor. Stimulation with tetradecanoyl phorbol acetate, causing monocytic differentiation, also resulted in down-regulation (two fold to threefold) of cystatin F expression, whereas the cystatin C expression was essentially unaltered in both experiments. The results suggest that cystatin F as an intracellular cysteine peptidase inhibitor with readily regulated expression, may be a candidate to control the cysteine peptidase activity known to be essential for antigen presentation in different blood cell lineages.

3.321 The Ccz1-Mon1 protein complex is required for the late step of multiple vacuole delivery pathways
Wang, C-W, Stromhaug, P.E., Shima, J. and Klionsky, J.
*J. Biol. Chem., **277(49)**, 47917-47927 (2002)*

Mon1 and Ccz1 were identified from a gene deletion library as mutants defective in the vacuolar import of aminopeptidase I (Ape1) via the cytoplasm to vacuole targeting (Cvt) pathway. The *mon1Δ* and *ccz1Δ* strains also displayed defects in autophagy and pexophagy, degradative pathways that share protein machinery and mechanistic features with the biosynthetic Cvt pathway. Further analyses indicated that Mon1, like Ccz1, was required in nearly all membrane-trafficking pathways where the vacuole represented the terminal acceptor compartment. Accordingly, both deletion strains had kinetic defects in the biosynthetic delivery of resident vacuolar hydrolases through the CPY, ALP, and MVB pathways. Biochemical and microscopy studies suggested that Mon1 and Ccz1 functioned after transport vesicle formation but before (or at) the fusion step with the vacuole. Thus, *ccz1Δ* and *mon1Δ* are the first mutants identified in screens for the Cvt and Apg pathways that accumulate precursor Ape1 within completed cytosolic vesicles. Subcellular fractionation and co-immunoprecipitation experiments confirm that Mon1 and Ccz1 physically interact as a stable protein complex termed the Ccz1-Mon1 complex. Microscopy of Ccz1 and Mon1 tagged with a fluorescent marker indicated that the Ccz1-Mon1 complex peripherally associated with a perivacuolar compartment and may attach to the vacuole membrane in agreement with their proposed function in fusion.

3.322 Lipid rafts are enriched in arachidonic acid and plasmenylethanolamine and their composition is independent of caveolin-1 expression: a quantitative electrospray ionization/mass spectrometric analysis

Pike, L.J., Han, X., Chung, K-N and Gross, R.W.
Biochemistry, ***41***, *2075-2088 (2002)*

Lipid rafts are specialized cholesterol-enriched membrane domains that participate in cellular signaling processes. Caveolae are related domains that become invaginated due to the presence of the structural protein, caveolin-1. In this paper, we use electrospray ionization mass spectrometry (ESI/MS) to quantitatively compare the phospholipids present in plasma membranes and nondetergent lipid rafts from caveolin-1-expressing and nonexpressing cells. Lipid rafts are enriched in cholesterol and sphingomyelin as compared to the plasma membrane fraction. Expression of caveolin-1 increases the amount of cholesterol recovered in the lipid raft fraction but does not affect the relative proportions of the various phospholipid classes. Surprisingly, ESI/MS demonstrated that lipid rafts are enriched in plasmenylethanolamines, particularly those containing arachidonic acid. While the total content of anionic phospholipids was similar in plasma membranes and nondetergent lipid rafts, the latter were highly enriched in phosphatidylserine but relatively depleted in phosphatidylinositol. Detergent-resistant membranes made from the same cells showed a higher cholesterol content than nondetergent lipid rafts but were depleted in anionic phospholipids. In addition, these detergent-resistant membranes were not enriched in arachidonic acid-containing ethanolamine plasmalogens. These data provide insight into the structure of lipid rafts and identify potential new roles for these domains in signal transduction.

3.323 Endoproteolysis of presenilin in vitro: inhibition by γ-secretase inhibitors

Campbell, W.A., Iskandar, M-K., Reed, M.L.O. and Xia, W.
Biochemistry, ***41***, *3372-3379 (2002)*

The final proteolytic step to generate the amyloid beta-protein (Abeta) of Alzheimer's disease (AD) from beta-amyloid precursor protein (APP) is achieved by presenilin (PS)-dependent gamma-secretase cleavage. AD-causing mutations in PS1 and PS2 result in a selective and significant increase in production of the more amyloidogenic Abeta42 peptide. PS1 and PS2 undergo endoproteolysis by an unknown enzyme termed presenilinase to generate the functional complex of N- and C-terminal fragments (NTF/CTF). To investigate the endoproteolytic activity that generates active PS, we used a mammalian cell-free system that allows de novo human PS NTF and CTF generation. PS NTF and CTF generation in vitro was observed in endoplasmic reticulum (ER)-enriched fractions of membrane vesicles and to a lesser extent in Golgi/trans-Golgi-network (TGN)-enriched fractions. AD-causing mutations in PS1 and PS2 did not alter de novo generation of PS fragments. Removal of peripheral membrane-associated and cytosolic proteins did not prevent de novo generation of fragments, indicating that presenilinase activity corresponds to an integral membrane protein. Among several general inhibitors of different protease classes that blocked the presenilinase activity, pepstatin A was the most potent inhibitor. Screening available transition state analogue gamma-secretase inhibitors led to the identification of two compounds that were able to prevent the de novo generation of PS fragments, with an expected inhibition of Abeta generation. Our studies provide a biochemical approach to characterize and identify this elusive presenilinase.

3.324 Annular α-synuclein protofibrils are produced when spherical protofibrils are incubated in solution or bound to brain-derived membranes
Ding, T.T., Lee, S-J., Rochet, J-C. and Lansbury, Jr., P.T.
*Biochemistry, **41**, 10209-10217 (2002)*

The Parkinson's disease substantia nigra is characterized by the loss of dopaminergic neurons and the presence of cytoplasmic fibrillar Lewy bodies in surviving neurons. The major fibrillar protein of Lewy bodies is alpha-synuclein. Two point mutations in the alpha-synuclein gene are associated with autosomal-dominant Parkinson's disease (FPD). Studies of the in vitro fibrillization behavior of the mutant proteins suggest that fibril precursors, or alpha-synuclein protofibrils, rather than the fibrils, may be pathogenic. Atomic force microscopy (AFM) revealed two distinct forms of protofibrillar alpha-synuclein: rapidly formed spherical protofibrils and annular protofibrils, which were produced on prolonged incubation of spheres. The spherical protofibrils bound to brain-derived membrane fractions much more tightly than did monomeric or fibrillar alpha-synuclein, and membrane-associated annular protofibrils were observed. The structural features of alpha-synuclein annular protofibrils are reminiscent of bacterial pore-forming toxins and are consistent with their porelike activity in vitro. Thus, abnormal membrane permeabilization may be a pathogenic mechanism in PD.

3.325 Characterization of isolated acidocalcisomes from *Toxoplasma gondii* Tachyzoites reveals a novel pool of hydrolysable polyphosphate
Rodrigues, C.O., Ruiz, F.A., Rohloff, P., Dcott, D.A. and Moreno, S.N.J.
J. Biol. Chem., 277(50), 48650-48656 (2002)

Toxoplasma gondii tachyzoites were fractionated by modification of an **iodixanol** density gradient method previously used for acidocalcisome isolation from *Trypanosoma cruzi* epimastigotes. Fractions were characterized using electron microscopy, x-ray microanalysis, and enzymatic markers, and it was demonstrated that the heaviest (pellet) fraction contains electron-dense vacuoles rich in phosphorus, calcium, and magnesium, as found before for acidocalcisomes. Staining with 4',6-diamidino-2-phenylindole (DAPI) indicated that poly- phosphate (polyP) was preferentially localized in this fraction together with pyrophosphate (PP_i). Using an enzyme-based method, millimolar levels (in terms of P_i residues) of polyP chains of less than 50 residues long and micromolar levels in polyP chains of about 700-800 residues long were found to be preferentially localized in this fraction. The fraction also contained the pyrophosphatase and polyphosphatase activities characteristic of acidocalcisomes. Western blot analysis using antibodies against proteins from micronemes, dense granules, rhoptries, and plasma membrane showed that the acidocalcisomal fraction was not contaminated by these other organelles. *T. gondii* polyP levels rapidly decreased upon exposure of the parasites to a calcium ionophore (ionomycin), to an inhibitor of the V-H^+-ATPase (bafilomycin A_1), or to the alkalinizing agent NH_4Cl. These changes were in parallel to an increase in intracellular Ca^{2+} concentration, suggesting a close association between polyP hydrolysis and Ca^{2+} release from the acidocalcisome. These results provide a useful method for the isolation and characterization of acidocalcisomes, showing that they are distinct from other previously recognized organelles present in *T. gondii*, and provide evidence for the role of polyP metabolism in response to cellular stress.

3.326 Formation of mutually exclusive Rab11 complexes with members of the family of Rab11-interacting proteins regulates Rab11 endocytic targeting and function
Meyers, J.M. and Prekeris, R.
J. Biol. Chem., 277(50), 49003-49010 (2002)

Several Rabs, including Rab11, regulate the traffic and sorting of proteins in the endosomal pathway. Recently, six novel Rab11 family interacting proteins (FIPs) were identified. Although they share little overall sequence homology, all FIPs contain a conserved Rab11-binding domain. Here we investigate the role of FIPs as Rab11-targeting proteins and show that the Rab11-binding domain assumes an α-helical structure, with the conserved residues forming a hydrophobic Rab11-binding patch. This hydrophobic patch mediates the formation of mutually exclusive complexes between Rab11 and various members of FIP protein family. Furthermore, the formation of Rab11/FIP complexes regulates Rab11 localization by recruiting it to distinct endocytic compartments. Thus, we propose that Rab11/FIP complexes serve as targeting patches, regulating Rab11 localization and recruitment of additional cellular factors to different endocytic compartments.

3.327 A specific structural requirement for ergosterol in long-chain fatty acid synthesis mutants important for maintaining raft domains in yeast

Eisenkolb, M., Zenzmaier, C., Leitner, E., and Schneiter, R.
*Mol. Biol. Cell, **13**, 4414-4428 (2002)*

Fungal sphingolipids contain ceramide with a very-long-chain fatty acid (C26). To investigate the physiological significance of the C26-substitution on this lipid, we performed a screen for mutants that are synthetically lethal with *ELO3*. Elo3p is a component of the ER-associated fatty acid elongase and is required for the final elongation cycle to produce C26 from C22/C24 fatty acids. *elo3Δ* mutant cells thus contain C22/C24- instead of the natural C26-substituted ceramide. We now report that under these conditions, an otherwise nonessential, but also fungal-specific, structural modification of the major sterol of yeast, ergosterol, becomes essential, because mutations in *ELO3* are synthetically lethal with mutations in *ERG6*. Erg6p catalyzes the methylation of carbon atom 24 in the aliphatic side chain of sterol. The lethality of an *elo3Δ erg6Δ* double mutant is rescued by supplementation with ergosterol but not with cholesterol, indicating a vital structural requirement for the ergosterol-specific methyl group. To characterize this structural requirement in more detail, we generated a strain that is temperature sensitive for the function of Erg6p in an *elo3Δ* mutant background. Examination of raft association of the GPI-anchored Gas1p and plasma membrane ATPase, Pma1p, in the conditional *elo3Δ erg6^{ts}* double mutant, revealed a specific defect of the mutant to maintain raft association of preexisting Pma1p. Interestingly, in an *elo3Δ* mutant at 37°C, newly synthesized Pma1p failed to enter raft domains early in the biosynthetic pathway, and upon arrival at the plasma membrane was rerouted to the vacuole for degradation. These observations indicate that the C26 fatty acid substitution on lipids is important for establishing raft association of Pma1p and stabilizing the protein at the cell surface. Analysis of raft lipids in the conditional mutant strain revealed a selective enrichment of ergosterol in detergent-resistant membrane domains, indicating that specific structural determinants on both sterols and sphingolipids are required for their association into raft domains.

3.328 Lipid-dependent subcellular relocalization of the acyl chain desaturase in yeast

Tatzer, V., Zellnig, G., Kohlwein, S.D. and Schneiter, R.
Mol. Biol. Cell, 13, 4429-4442 (2002)

The degree of acyl chain desaturation of membrane lipids is a critical determinant of membrane fluidity. Temperature-sensitive mutants of the single essential acyl chain desaturase, Ole1p, of yeast have previously been isolated in screens for mitochondrial inheritance mutants (Stewart, L.C., and Yaffe, M.P. (1991). J. Cell Biol. *115*, 1249-1257). We now report that the mutant desaturase relocalizes from its uniform ER distribution to a more punctuate localization at the cell periphery upon inactivation of the enzyme. This relocalization takes place within minutes at nonpermissive conditions, a time scale at which mitochondrial morphology and inheritance is not yet affected. Relocalization of the desaturase is fully reversible and does not affect the steady state localization of other ER resident proteins or the kinetic and fidelity of the secretory pathway, indicating a high degree of selectivity for the desaturase. Relocalization of the desaturase is energy independent but is lipid dependent because it is rescued by supplementation with unsaturated fatty acids. Relocalization of the desaturase is also observed in cells treated with inhibitors of the enzyme, indicating that it is independent of temperature-induced alterations of the enzyme. In the absence of desaturase function, lipid synthesis continues, resulting in the generation of lipids with saturated acyl chains. A model is discussed in which the accumulation of saturated lipids in a microdomain around the desaturase could induce the observed segregation and relocalization of the enzyme.

3.329 The mechanism of γ-secretase activities through high molecular weight complex formation pof presenilins is conserved in *Drosophila melanogaster* and mammals
Takasugi, N., Takahashi, Y., Morohashi, Y. and Tomita, T.
J. Biol. Chem., 277(51), 50198-50205 (2002)

Mutations in presenilin 1 (*PS1*) and *PS2* genes contribute to the pathogenesis of early onset familial Alzheimer's disease by increasing secretion of the pathologically relevant Aβ42 polypeptides. PS genes are also implicated in Notch signaling through proteolytic processing of the Notch receptor in *Caenorhabditis elegans*, *Drosophila melanogaster*, and mammals. Here we show that *Drosophila* PS (Psn) protein undergoes endoproteolytic cleavage and forms a stable high molecular weight (HMW) complex in *Drosophila* S2 or mouse neuro2a (N2a) cells in a similar manner to mammalian PS. The loss-of-function recessive point mutations located in the C-terminal region of Psn, that cause an early pupal-lethal phenotype resembling *Notch* mutant *in vivo*, disrupted the HMW complex formation, and abolished γ-secretase activities in cultured cells. The overexpression of Psn in mouse embryonic fibroblasts lacking *PS1* and *PS2* genes rescued the Notch processing. Moreover, disruption of the expression of Psn by double-stranded RNA-mediated interference completely abolished the γ-secretase activity in S2 cells. Surprisingly, γ-secretase activity dependent on wild-type Psn was associated with a drastic overproduction of Aβ1-42 from human βAPP in N2a cells, but not in S2 cells. Our data suggest that the mechanism of γ-secretase activities through formation of HMW PS complex, as well as its abolition by loss-of-function mutations located in the C terminus, are highly conserved features in *Drosophila* and mammals.

3.330 Axonal transport of mitochondria to synapses depends on Milton, a novel *Drosophilia* protein
Stowers, R.S., Megeath, L.J., Gorska-Andrzejak, J., Meinertzhagen, I.A. and Schwartz, T.L.
Neuron, 36, 1063-1077 (2002)

A protein required to localize mitochondria to *Drosophila* nerve terminals has been identified genetically. Photoreceptors mutant for *milton* show aberrant synaptic transmission despite normal phototransduction. Without Milton, synaptic terminals and axons lack mitochondria, although mitochondria are numerous in neuronal cell bodies. In contrast, synaptic vesicles continue to be transported to and concentrated at synapses. Milton protein is associated with mitochondria and is present primarily in axons and synapses. A likely explanation of the apparent trafficking defect is offered by the coimmunoprecipitation of Milton and kinesin heavy chain. Transfected into HEK293T cells, Milton induces a redistribution of mitochondria within the cell. We propose that Milton is a mitochondria-associated protein required for kinesin-mediated transport of mitochondria to nerve terminals.

3.331 The organizing principle in the formation of the T cell receptor-CD3 complex
Call, M.E., Pyrdol, J., Wiedmann, M. and Wucherpfennig, K.W.
*Cell, **111**, 967-979 (2002)*

The T cell receptor (TCR) serves a critical function in the immune system and represents one of the most complex receptor structures. A striking feature is the presence of nine highly conserved, potentially charged residues in the transmembrane helices. Previous models have attempted to explain assembly based on pairwise interactions of these residues. Using a novel method for the isolation of intact radiolabeled protein complexes, we demonstrate that one basic and two acidic transmembrane residues are required for the assembly of each of the three signaling dimers with the TCR. This remarkable three-helix arrangement applies to all three assembly steps and represents the organizing principle for the formation of this intricate receptor structure.

3.332 Src homology 2 domain-containing leukocyte phosphoprotein of 76 kDA and phospholipase Cγ1 are required for NF-κB activation and lipid raft recruitment of protein kinase Cθ induced by T cell costimulation

Dienz, O. et al

J. Immunol., ***169****, 365-372 (2002)*

The NF-κB activation pathway induced by T cell costimulation uses various molecules including Vav1 and protein kinase C (PKC)*θ*. Because Vav1 inducibly associates with further proteins including phospholipase C (PLC)γ 1 and Src homology 2 domain-containing leukocyte phosphoprotein of 76 kDa (SLP-76), we investigated their role for NF-κB activation in Jurkat leukemia T cell lines deficient for expression of these two proteins. Cells lacking SLP-76 or PLCγ1 failed to activate NF-κB in response to T cell costimulation. In contrast, replenishment of SLP-76 or PLCγ1 expression restored CD3/CD28-induced IκB kinase (IKK) activity as well as NF-κB DNA binding and transactivation. PKC*θ* activated NF-κB in SLP-76- and PLCγ1-deficient cells, showing that PKC*θ* is acting further downstream. In contrast, Vav1-induced NF-κB activation was normal in SLP-76$^-$ cells, but absent in PLCγ1$^-$ cells. CD3/CD28-stimulated recruitment of PKCθ and IKKγ to lipid rafts was lost in SLP-76- or PLCγ1-negative cells, while translocation of Vav1 remained unaffected. Accordingly, recruitment of PKC*θ* to the immunological synapse strictly relied on the presence of SLP-76 and PLCγ1, but synapse translocation of Vav1 identified in this study was independent from both proteins. These results show the importance of SLP-76 and PLCγ1 for NF-κB activation and raft translocation of PKC*θ* and IKKγ.

3.333 Genetic analysis of iron citrate toxicity in yeast: implications for mammalian iron homeostasis

Chen, O.S., Hemenway, S. and Kaplan, J.

Proc. Natl. Acad. Sci., USA, ***99(26)****, 16922-16927 (2002)*

Deletion of the yeast homologue of frataxin, *YFH1*, results in mitochondrial iron accumulation and respiratory deficiency (petite formation). We used a genetic screen to identify mutants that modify iron-associated defects in respiratory activity in Δ*yfh1* cells. A deletion in the peroxisomal citrate synthase *CIT2* in Δ*yfh1* cells decreased the rate of petite formation. Conversely, overexpression of *CIT2* in Δ*yfh1* cells increased the rate of respiratory loss. Citrate toxicity in Δ*yfh1* cells was dependent on iron but was independent of mitochondrial respiration. Citrate toxicity was not restricted to iron-laden mitochondria but also occurred when iron accumulated in cytosol because of impaired vacuolar iron storage. These results suggest that high levels of citrate may promote iron-mediated tissue damage.

3.334 Regulated secretion and subcellular distribution of rabbit lacrimal gland alpha-fucosidases
Gierow, J., Andersson, S.V. and Sjögren, E.C.
Invest. Ophthamol. Vis. Sci., ***43***, *E-Abstract 3125 (2002)*

Purpose: Our previous results have indicated the presence of two forms of alpha-fucosidase, one acidic and one neutral, that are expressed and secreted by rabbit lacrimal acinar cells in primary culture (IOVS 42: s259, 2001). The purpose of the present study was to further characterize the two forms of alpha-fucosidase regarding their subcellular distribution and regulated secretion
Methods: Single acinar cells were isolated from female NZW rabbit lacrimal glands and cultured for 40 h on Matrigel, thus allowing the cells to re-organize into acinar-like structures. The cells were then rinsed and incubated at 37C for 1 h in the absence or presence of 0.1 mM carbachol. Media were collected and analyzed for alpha-fucosidase catalytic activity, at pH 4.0 and pH 7.0, using a 4-methyl umbelliferyl conjugate as substrate.Tissue and cultured cells were homogenized and fractionated by centrifugation yielding a soluble, a nuclear and a microsomal fraction. The membrane fractions were further fractionated by density gradient centrifugation on 10-30% Iodioxanol (**Optiprep**) gradients, and the resulting fractions were analyzed for fucosidase activity.
Results: Secretion of the acidic and the neutral form were both stimulated 5-fold by carbachol. Subcellular fractionation of tissue resulted in 60% recovery of both the acidic and the neutral fucosidase activity in the soluble fraction and 15% in the nuclear (low-speed) pellet, whereas fractionation of cultured cells resulted in a reversed distribution, the difference probably a result of the harsher homogenization procedures used for tissue. Density gradient centrifugation of the membrane fractions revealed the presence of at least three fucosidase-containing membrane populations: One fraction of low density of unknown origin, one high-density, potentially lysosomal population and one intermediate fraction, possibly Golgi-related.
Conclusion: No sigificant differences were observed between the distribution and secretion of the acidic and neutral forms of alpha-fucosidase, indicating that they are sequestered in the same endomembrane compartments and that they are under the same secretory control.

3.335 Human B1 and B2 bradykinin receptors and their agonists target caveolae-related lipid rafts to different degrees in HEK293 cells
Lamb, M.E., Zhang, C., Shea, T., Kyle, D.J. and Leeb-Lundberg, L.M.F.
Biochemistry, ***41***, *14340-14347 (2002)*

To address the targeting of G protein-coupled receptors to caveolae-related lipid rafts (CLR), we studied the human B2 (B2R) and B1 (B1R) bradykinin receptor subtypes in HEK293 cells. CLR were enriched on the basis of their unique buoyant density and composition of cholesterol, caveolin-1, and flotillin-1 but not clathrin. CLR contained B2R and B1R as determined by both receptor immunoblotting and the increase in specific activity of receptor agonist binding to cells at both 4 and 37 degrees C when binding was followed by CLR enrichment. B2R was highly enriched in this fraction, whereas B1R was not enriched. Furthermore, acid washing of cells prior to cell disruption minimally affected the CLR-associated B2R agonist binding, whereas it dissociated a major portion of the CLR-associated B1R agonist binding. In addition, when agonist binding at 4 degrees C was followed by an increase in the temperature to 37 degrees C, B2R agonist binding in CLR transiently increased, and this increase was dependent on the C-terminal domain. On the other hand, B1R agonist binding remained unchanged and was independent of the C-terminal domain. Our results show that B2R is constitutively targeted to CLR in HEK293 cells and appears to shuttle the agonist through these domains, whereas B1R may be there by default.

3.336 Hormone-induced subcellular redistribution of trimeric G proteins
Svobada, P. and Novotny, J.
*Cell. Mol. Life Sci., **59**, 501-512 (2002)*

Trimeric guanine nucleotide-binding proteins (G proteins) function as the key regulatory elements in a number of transmembrane signaling cascades where they convey information from agonist-activated receptors to effector molecules. The subcellular localization of G proteins is directly related to their functional role, i.e., the dominant portion of the cellular pool of G proteins resides in the plasma membrane. An intimate association of G protein subunits with the plasma membrane has been well known for a long time. However, results of a number of independent studies published in the past decade have indicated clearly that exposure of intact target cells to agonists results in subcellular redistribution of the cognate G proteins from plasma membranes to the light-vesicular membrane fractions, in internalization from the cell surface into the cell interior and in transfer from the membrane to the soluble cell fraction (high-speed supernatant), i.e. solubilization. Solubilization of G protein αsubunits as a consequence of stimulation of G protein-coupled receptors (GPCRs) with agonists has also been observed in isolated membrane preparations. The membrane -cytosol shift of G proteins was detected even after direct activation of these proteins by non-hydrolyzable analogues of GTP or by cholera toxin-induced ADP-ribosylation. In addition, prolonged stimulation of GPCRs with agonists has been shown to lead to down-regulation of the relevant G proteins. Together, these data suggest that G proteins might potentially participate in a highly complex set of events, which are gene-rally termed desensitization of the hormone response. Internalization, subcellular redistribution, solubiliza-tion, and down-regulation of trimeric G proteins may thus provide an additional means (i.e., beside receptor -based mechanisms) to dampen the hormone or neurotransmitter response after sustained (long-term) exposure.

3.337 Reversible depression of transcription during hibernation
van Breukelen, F. and Martin, S.L.
J. Comp. Physiol. B., 172, 355-361 (2002)

Mammalian hibernators downregulate processes of energy production and consumption while maintaining cellular homeostasis. Energetic costs of transcription must be balanced with demands for gene products. Data from nuclear run-on assays indicate transcriptional initiation is reduced two fold in torpid golden-mantled ground squirrels (*Spermophilus lateralis*) as compared to euthermic animals between bouts of torpor. In addition, elongation rates across the temperature range experienced by hibernators indicate a virtual arrest of transcription at the low body temperatures of torpor. Finally, there is no seasonal compensation or species-specific adaptation for increased elongational capacity in the cold. Thus, it appears that hibernators are not specifically adapted to continue transcription during torpor. Taken together, these data indicate that transcription arrests during torpor because of a moderate depression of initiation and a more severe inhibition of elongation, largely due to temperature effects. Restoration of euthermic body temperatures during the interbout arousals reverses this transcriptional depression and permits gene expression.

3.338 Myocilin is associated with mitochondria in human trabecular meshwork cells
Wentz-Hunter, K., Ueda, J., Shimuzi, N. and Yue, B.Y.J.T.
*J. Cell. Physiol., **190**, 46-53 (2002)*

The trabecular meshwork (TM) is a specialized tissue located at the chamber angle of the eye next to the cornea. This tissue is believed to be responsible for regulation of the aqueous humor outflow and control of the intraocular pressure (IOP). Alterations in functions of the TM may lead to IOP elevation and development of glaucoma, a major cause of blindness. The myocilin gene has recently been directly linked to open-angle glaucomas. The gene product was originally identified as a protein inducible in TM cells by treatment with glucocorticoids such as dexamethasone (DEX) and termed TIGR (TM inducible-glucocorticoid resp-onse). The exact nature and function of the myocilin protein so far still remain elusive. In this study, myocil-in was localized to the perinuclear region of both DEX-treated and control TM cells. Its distribution over-lapped considerably with that of mitochondria. Subcellular fractionation and Western blot analyses suggest-ed a rather extensive association of myocilin with mitochondria. The DEX-treated TM cells were found to undergo apoptosis, when exposed to anti-Fas antibody, to a signilicantly higher degree than the untreated control cells. It appears that the TM cell integrity remains intact after DEX treatment. However, the induc-ed myocilin or myocilin-mitochondria association seems to render the cells more susceptible to a second stress or challenge. This vulnerability may be the basis that ultimately leads to pathological consequences.

3.339 RVS161p and sphingolipids are required for actin repolarization following salt stress
Balguerie, A., Bagnat, M., Bonneu, M., Aigle, M. and Breton, A.M.
*Eukaryotic Cell, **1**, 1021-1031 (2002)*
In *Saccharomyces cerevisiae,* the actin cytoskeleton is depolarized by NaCl stress. In this study, the response was maximal after 30 mm, and then actin patches repolarized. Rvsl6lp was required for actin repolarization because the *rvs161Δ* mutant did not repolarize actin patches after growth in a salt medium. Mutations suppressing the rvsl6Th-related salt sensitivity all occurred in genes required for sphingolipid biosynthesis: *FEN1, SUR4, SUR2, SUR!,* and *IPT1*. These suppressors also suppressed *act1-l*-related salt sensitivity and the defect in actin repolarization of the *rvs161Δ* mutant, providing a link between sphingolipids and actin polarization. Indeed, deletion of the suppressor genes suppressed the *rvs161Δ* defect in actin repolarization in two ways: either actin was not depolarized at the wild-type level in a set of suppressor mutants, or actin was repolarized in the absence of Rvs16lp in the other suppressor mutants. Rvsl6lp was localized as cortical patches that concentrated at polarization sites, i.e., bud emergence and septa, and was found to be associated with lipid rafts. An important link between sphingolipids and actin polarization is that Rvsl61p was required for actin repolarization and was found to be located in lipid rafts.

3.340 Huntingtin-associated protein 1 interacts with hepatocyte growth factor-regulated tyrosine kinase substrate and functions in endosomal trafficking
Li, Y., Chin, L-S., Levey, A.L. and Li, L.
*J. Biol. Chem., **277(31)**, 28212-28221 (2002)*

Huntingtin-associated protein 1 (HAP1) is a novel protein of unknown function with a higher binding affinity for the mutant form of Huntington's disease protein huntingtin. Here we report that HAP1 interacts with hepatocyte growth factor-regulated tyrosine kinase substrate (Hrs), a mammalian homologue of yeast vacuolar protein sorting protein Vps27p involved in the endosome-to-lysosome trafficking. This novel interaction was identified in a yeast two-hybrid screen using full-length Hrs as bait, and confirmed by *in vitro* binding assays and co-immunoprecipitation experiments. Deletion analysis reveals that the association of HAP1 with Hrs is mediated via a coiled-coil interaction between the central coiled-coil domains of both proteins. Immunofluorescence and subcellular fractionation studies show that HAP1 co-localizes with Hrs on early endosomes. Like Hrs, overexpression of HAP1 causes the formation of enlarged early endosomes, and inhibits the degradation of internalized epidermal growth factor receptors. Whereas overexpression of HAP1 does not affect either constitutive or ligand-induced receptor-mediated endocytosis, it potently blocks the trafficking of endocytosed epidermal growth factor receptors from early endosomes to late endosomes. These findings implicate, for the first time, the involvement of HAP1 in the regulation of vesicular trafficking from early endosomes to the late endocytic compartments.

3.341 The adenosine 2b receptor is required to the plasma membrane and associates with E3KARP and ezrin upon agonist stimulation
Sitaraman, S.V. et al
*J. Biol. Chem., **277(36)**, 33188-33195 (2002)*

We have previously shown that adenosine is formed in the intestinal lumen during active inflammation from neutrophil-derived 5'-AMP. Acting through the adenosine A2b receptor (A2bR), the luminally derived adenosine induces vectorial chloride secretion and a polarized secretion of interleukin-6 to the intestinal lumen. Although some G protein-coupled receptors interact with anchoring or signaling molecules, not much is known in this critical area for the A2bR. We used the model intestinal epithelial cell line, T84, and Caco2-BBE cells stably transfected with GFP-A2b receptor to study the intestinal A2bR. The A2bR is present in both the apical and basolateral membranes of intestinal epithelia. Apical or basolateral stimulation of the A2bR induces recruitment of the receptor to the plasma membrane and caveolar fractions. The A2bR co-immunoprecipitates with E3KARP and ezrin upon agonist stimulation. Ezrin interacts with E3KARP and PKA and the interaction between ezrin and E3KARP is enhanced by agonist stimulation. Our data suggest that the A2bR is recruited to the plasma membrane upon apical or basolateral agonist stimulation and interacts with E3KARP and ezrin. We speculate that such an interaction may not only anchor the A2bR to the plasma membrane but may also function to stabilize the receptor in a signaling complex in the plasma membrane.

3.342 Organization of the recveptor-kinase signaling array that regulates *Escherichia coli* chemotaxis
Levit, M.N., Grebe, T.W. and Stock, J.B.
*J. Biol. Chem., **277(39)**, 36748-36754 (2002)*

Motor behavior in prokaryotes is regulated by a phosphorelay network involving a histidine protein kinase, CheA, whose activity is controlled by a family of Type I membrane receptors. In a typical *Escherichia coli* cell, several thousand receptors are organized together with CheA and an Src homology 3-like protein, CheW, into complexes that tend to be localized at the cell poles. We found that these complexes have at least 6 receptors per CheA. CheW is not required for CheA binding to receptors, but is essential for kinase activation. The kinase activity per mole of bound CheA is proportional to the total bound CheW. Similar results were obtained with the *E. coli* serine receptor, Tsr, and the *Salmonella typhimurium* aspartate receptor, Tar. In the case of Tsr, under conditions optimal for kinase activation, the ratio of subunits in complexes is ~6 Tsr:4 CheW:1 CheA. Our results indicate that information from numerous receptors is integrated to control the activity of a relatively small number of kinase molecules.

3.343 A novel membrane protein, Ros3p, is required for phospholipid translocation across the plasma membrane in *Saccharomyces cerevisiae*
Kato, U. et al
J. Biol. Chem., ***277(40)***, *37855-37862 (2002)*

Ro09-0198 (Ro) is a tetracyclic peptide antibiotic that binds specifically to phosphatidylethanolamine (PE) and causes cytolysis. To investigate the molecular basis of transbilayer movement of PE in biological membranes, we have isolated a series of budding yeast mutants that are hypersensitive to the Ro peptide. One of the most sensitive mutants, designated *ros3* (Ro-sensitive 3), showed no significant change in the cellular phospholipid composition or in the sensitivity to amphotericin B, a sterol-binding polyene macrolide antibiotic. These results suggest that the mutation of *ros3* affects the PE organization on the plasma membrane, rather than PE synthesis or overall organization of the membrane structures. By functional complementation screening, we identified the gene *ROS3* affected in the mutant, and we showed that the hypersensitive phenotype was caused by the defective expression of the *ROS3* gene product, Ros3p, an evolutionarily conserved protein with two putative transmembrane domains. Disruption of the *ROS3* gene resulted in a marked decrease in the internalization of fluorescence-labeled analogs of PE and phosphatidylcholine, whereas the uptake of fluorescence-labeled phosphatidylserine and endocytic markers was not affected. Neither expression levels nor activities of ATP-binding cassette transporters of the *ros3*Δ cells differed from those of wild type cells, suggesting that Ros3p is not related to the multidrug resistance activities. Immunochemical analyses of the structure and subcellular localization showed that Ros3p was a glycosylated membrane protein localized in both the plasma membrane and the endoplasmic reticulum, and that a part of Ros3p was associated with the detergent-insoluble glycolipid-enriched complexes. These results indicate that Ros3p is a membrane glycoprotein that plays an important role in the phospholipid translocation across the plasma membrane.

3.344 The biofunctional activity of ubiquinone in lysosomal membranes
Nohl, H. and Gille, L.
Biogerontology, ***3***, *125-131 (2002)*

Ubiquinone is inhomogenously distributed insubcellular biomembranes. Apart frommitochondria where ubiquinone was demonstratedto exert bioenergetic and pathophysiologicalfunctions, unusually high levels of ubiquinonewere also reported to exist in Golgi vesiclesand lysosomes. In lysosomes the interiordiffers from other organelles by the low pH-value, which is important not only to arrestproteins but also to ensure optimal activity ofhydrolytic enzymes. Since redox-cycling ofubiquinone is associated with the acceptanceand release of protons, we assumed thatubiquinone is a part of a redox chaincontributing to unilateral proton distribution.A similar function of ubiquinone was earliersuggested by Crane to operate in Golgivesicles. Support for the involvement ofubiquinone in a presumed couple ofredox-carriers came from our observation thatalmost 70% of total lysosomal ubiquinone wasin the divalently reduced state. Furtherreduction was seen in the presence of externalNADH. Analysis of the components involved inthe transfer of reducing equivalents fromcytosolic NADH to ubiquinone revealed theexistence of a FAD-containingNADH-dehydrogenase. The latter was found toreduce ubiquinone by means of a b-typecytochrome. Proton translocation into theinterior was linked to the activity of thenovel lysosomal redox chain. Oxygen was foundto be the terminal electron acceptor, therebyalso regulating acidification of the lysosomalmatrix. In contrast to mitochondrialrespiration, oxygen was only trivalently reduced,giving rise to the release ofHO ●-radicals. The role of this novelproton-pumping redox chain and the significanceof the associated ROS formation has to beelucidated.

3.345 Palmitic is the main fatty acid carried by lipids of detergent-resistant membrane fractions from neural and non-neural cells
Pitto, M. et al
Neurochem. Res., ***27(7/8)***, *729-734 (2002)*

Lipids extracted from detergent-resistant membrane fractions, thought to derive from membrane domains, were analyzed for fatty acid composition. The proportion of palmitic acid in fractions isolated from neurons (cerebellar granule cells) and from neural-like cell lines (neuroblastoma-glioma NG108-15) nearly doubled (reaching about 54% of total fatty acids) with respect to cell WCL, indicating their enrichment in palmitic acid-carrying lipids. The proportion of palmitic acid in detergent-resistant fractions obtained from caveolin-transfected NG108-15 cells was comparable with that obtained from caveolin-negative cells, ruling out a specific role of this protein in recruiting palmitoylated lipid species. The enrichment in palmitic acid was remarked also in membrane fractions isolated from non-neuronal cell lines (A431) using either detergents or detergent-free techniques. Lipid fractionation and mass spectrometry experiments show that palmitic acid–rich phosphatidylcholine species are responsible of the peculiar fatty acid composition of these fractions. All together these results suggest that the enrichment in palmitic acid–rich phosphatidylcholine species is a common feature of neural and non-neural cell lines and may play a major role in the biogenesis of membrane domains.

3.346 Phosphorylation of FcγRIIA is required for the receptor-induced actin rearrangement and capping: the role of membrane rafts
Kwiatkowska, K., Frey, J. and Sobota, A.
J. Cell Sci., ***116***, *537-550 (2003)*

Activation of Fcγ receptor II (FcγRII) induces rearrangement of the actin-based cytoskeleton that serves as a driving force for FcRII-mediated phagocytosis and FcγRII capping. To get insight into the signaling events that lead to the actin reorganization we investigated the role of raft-associated Src family tyrosine kinases in capping of FcγRII in U937 cells. After crosslinking, FcγRII was found to be recruited to detergent-resistant membrane domains (DRMs), rafts, where it coexisted with Lyn kinase and underwent tyrosine phosphorylation. Lyn was displaced from DRMs under the influence of DL-α-hydroxymyristic acid and 2-bromopalmitic acid, agents blocking N-terminal myristoylation and palmitoylation of proteins, respectively, and after disruption of DRM integrity by depletion of plasma membrane cholesterol with ß-cyclodextrin. Under these conditions, phosphorylation of the crosslinked FcγRII was diminished and assembly of FcγRII caps was blocked. The similar reduction of FcγRII cap formation correlated with inhibition of receptor phosphorylation was achieved with the use of PP1 and herbimycin A, specific inhibitors of Src family tyrosine kinases. Phosphorylation of FcγRIIA expressed in BHK cells, lacking endogenous FcγRs, was abolished by substitution of tyrosine 298 by phenylalanine in the ITAM of the receptor. The mutant receptor did not undergo translocation towards cap-like structures and failed to promote the receptor-mediated spreading of the cells, as compared to BHK cells transfected with the wild-type FcγRIIA. On the basis of these data, we suggest that tyrosine phosphorylation of activated FcγRIIA by raft-residing tyrosine kinases of the Src family triggers signaling pathways that control the rearrangement of the actin cytoskeleton required for FcγRII-mediated motility.

3.347 Subcellular localization of host and viral proteins associated with tobamovirus RNA replication
Hagiwara, Y. et al
EMBO J., ***22(2)***, *344-353 (2003)*

Arabidopsis TOM1 (AtTOM1) and TOM2A (AtTOM2A) are integral membrane proteins genetically identified to be necessary for efficient intracellular multiplication of tobamoviruses. AtTOM1 interacts with the helicase domain polypeptide of tobamovirus-encoded replication proteins and with AtTOM2A, suggest-ing that both AtTOM1 and AtTOM2A are integral components of the tobamovirus replication complex. We show here that AtTOM1 and AtTOM2A proteins tagged with green fluorescent protein (GFP) are targeted to the vacuolar membrane (tonoplast)-like structures in plant cells. In subcellular fractionation analyses, GFPAtTOM2A, AtTOM2A and its tobacco homolog NtTOM2A were predominantly fractionated to low-density tonoplast-rich fractions, whereas AtTOM1–GFP, AtTOM1 and its tobacco homolog NtTOM1 were distributed mainly into the tonoplast-rich fractions and partially into higher-buoyant-density fractions con-taining membranes from several other organelles. The tobamovirus-encoded replication proteins were co-fractionated with both NtTOM1 and viral RNA-dependent RNA

polymerase activity. The replication proteins were also found in the fractions containing non-membrane-bound proteins, but neither NtTOM1 nor the polymerase activity was detected there. These observations suggest that the formation of tobamo-viral RNA replication complex occurs on TOM1-containing membranes and is facilitated by TOM2A.

3.348 Amyloidgenic processing of the Alzheimer β-amyloid precursor protein depends on lipid rafts
Ehehalt, R.E., Keller, P., Haass, C., Thiele, C. and Simons, K
*J. Cell Biol., **160(1)**, 113-123 (2003)*

Formation of senile plaques containing the ß-amyloid peptide (Aß) derived from the amyloid precursor protein (APP) is an invariant feature of Alzheimer's disease (AD). APP is cleaved either by ß-secretase or by α-secretase to initiate amyloidogenic (release of Aß) or nonamyloidogenic processing of APP, respectively. A key to understanding AD is to unravel how access of these enzymes to APP is regulated. Here, we demonstrate that lipid rafts are critically involved in regulating Aß generation. Reducing cholesterol levels in N2a cells decreased Aß production. APP and the ß-site APP cleavage enzyme (BACE1) could be induced to copatch at the plasma membrane upon cross-linking with antibodies and to segregate away from nonraft markers. Antibody cross-linking dramatically increased production of Aß in a cholesterol-dependent manner. Aß generation was dependent on endocytosis and was reduced after expression of the dynamin mutant K44A and the Rab5 GTPase-activating protein, RN-tre. This inhibition could be overcome by antibody cross-linking. These observations suggest the existence of two APP pools. Although APP inside raft clusters seems to be cleaved by ß-secretase, APP outside rafts undergoes cleavage by α-secretase. Thus, access of α- and ß-secretase to APP, and therefore Aß generation, may be determined by dynamic interactions of APP with lipid rafts.

3.349 Independent segregation of human immunodeficiency virus type I Gag protein complexes and lipid rafts
Ding, L., Derdowsky, A., Wang, J-J- and Spearman, P.
*J. Virol., **77(3)**, 1916-1926 (2003)*

Formation of human immunodeficiency virus type 1 (HIV-1) particles takes place at the plasma membrane of cells and is directed by the $Pr55^{Gag}$ polyprotein. A functional assembly domain (the M domain) within the N-terminal portion of $Pr55^{Gag}$ mediates the interaction of Gag with cellular membranes. However, the determinants that provide specificity for assembly on the plasma membrane, as opposed to intracellular membranes, have not been identified. Recently, it was reported that $Pr55^{Gag}$ interacts with lipid raft microdomains of the plasma membrane. We sought to identify the domains within $Pr55^{Gag}$ that contribute to lipid raft association of Gag. Here we demonstrate that the I domain is required for interaction with detergent-resistant membrane fractions (DRMs). Mutation of key I-domain residues or loss of myristylation abrogated the association of Gag with DRMs. Thus, the I domain and the M domain combine to mediate Gag-lipid raft interactions as defined by these biochemical criteria. However, Gag protein complexes defined by flotation studies were much denser than classical lipid rafts, failed to incorporate classical lipid raft marker proteins, and were not disrupted by cholesterol extraction. Large sheets of Gag protein were identified in DRM fractions upon examination by electron microscopy. These results indicate that HIV-1 $Pr55^{Gag}$ forms detergent-resistant complexes at the cellular periphery that are distinct from lipid raft microdomains.

3.350 A third human carnitine/organic cation transporter (*OCTN3*) as a candidate for the 5q31 Crohn's disease locus (*IBD5*)
Lamhonwah, A-M., Skaug, J., Scherer, S. and Tein, I.
*Biochem. Biophys. Res. Comm., **301**, 98-101 (2003)*

Organic cation transporters function primarily in the elimination of cationic drugs in kidney, intestine, and liver [1, 2 and 3]. The murine organic cation/carnitine (*Octn*) transporter family, *Octn1*, *Octn2*, and *Octn3* is clustered on mouse chromosome 11 (NCBI Accession No NW_00039). The human *OCTN1* and *OCTN2* orthologs map to the syntenic *IBD5* locus at 5q31 [1], which has been shown to confer susceptibility to Crohn's disease [4]. We show that the human OCTN3 protein, whose corresponding gene is not yet cloned or annotated in the human reference DNA sequence, does indeed exist and is uniquely involved in carnitine-dependent transport in peroxisomes. Its functional properties and inferred chromosomal location implicate it for involvement in Crohn's disease.

3.351 Regulation of vascular endothelial growth factor receptor-2 activity by caveolin-1 and plasma membrane cholesterol
Labrecque, L. et al
*Mol. Biol. Cell, **14**, 334-347 (2003)*

The stimulation of vascular endothelial growth factor receptor-2 (VEGFR-2) by tumor-derived VEGF represents a key event in the initiation of angiogenesis. In this work, we report that VEGFR-2 is localized in endothelial caveolae, associated with caveolin-1, and that this complex is rapidly dissociated upon stimulation with VEGF. The kinetics of caveolin-1 dissociation correlated with those of VEGF-dependent VEGFR-2 tyrosine phosphorylation, suggesting that caveolin-1 acts as a negative regulator of VEGF R-2 activity. Interestingly, we observed that in an overexpression system in which VEGFR-2 is constitutively active, caveolin-1 overexpression inhibits VEGFR-2 activity but allows VEGFR-2 to undergo VEGF-dependent activation, suggesting that caveolin-1 can confer ligand dependency to a receptor system. Removal of caveolin and VEGFR-2 from caveolae by cholesterol depletion resulted in an increase in both basal and VEGF-induced phosphorylation of VEGFR-2, but led to the inhibition of VEGF-induced ERK activation and endothelial cell migration, suggesting that localization of VEGFR-2 to these domains is crucial for VEGF-mediated signaling. Dissociation of the VEGFR-2/caveolin-1 complex by VEGF or cyclodextrin led to a PP2-sensitive phosphorylation of caveolin-1 on tyrosine 14, suggesting the participation of Src family kinases in this process. Overall, these results suggest that caveolin-1 plays multiple roles in the VEGF-induced signaling cascade.

3.352 Regulation of integrin growth factor interactions in oligodendrocytes by lipid raft microdomains
Baron, W., Decker, L., Colognato, H. and ffrench-Constant, C.
*Current Biol., **13**, 151-155 (2003)*

Individual growth factors can regulate multiple aspects of behavior within a single cell during differentiation, with each signaling pathway controlled independently and also responsive to other receptors such as cell surface integrins. The mechanisms by which this is achieved remain poorly understood. Here we use myelin-forming oligodendrocytes and their precursors to examine the role of lipid rafts, cholesterol and sphingolipid-rich microdomains of the cell membrane implicated in cell signaling [1]. In these cells, the growth factor PDGF has sequential and independent roles in proliferation and survival [2and 3]. We show that the oligodendrocyte PDGFα receptor becomes sequestered in a raft compartment at the developmental stage when PDGF ceases to promote proliferation, but is now required for survival. We also show that laminin-2, which is expressed on axons in the CNS and which provides a target-dependent signal for oligodendrocyte survival by amplification of PDGFαR signaling [4] induces clustering of the laminin binding integrin α6β1 with the PDGFαR-containing lipid raft domains. This extracellular matrix-induced colocalization of integrin and growth factor receptor generates a signaling environment within the raft for survival-promoting PI3K/Akt activity. These results demonstrate novel signaling roles for lipid rafts that ensure the separation and amplification of growth factor signaling pathways during development.

3.353 SR-BI does not require raft/caveola localization for cholesteryl ester selective uptake in the human adrenal cell line NCI-H295R
Briand, O. et al
Biochim. Biophys. Acta, 163, 42-50 (2003)

Class B type I scavenger receptor (SR-BI) mediates the selective uptake of high-density lipoprotein (HDL)-derived cholesteryl esters (HDL-CE) in steroidogenic cells and hepatocytes. SR-BI is enriched in the caveolae of some cell types, genetically modified or not, and these domains have already been shown to constitute primary acceptors for HDL-CE. Nevertheless, the fate of caveola-free cell types has not yet been discussed.
NCI-H295R, a human adrenal cell line, highly active in HDL-CE uptake via SR-BI, does not display any morphologically defined caveolae and expresses caveolin at a very low level. Using two different fractionation protocols, we have shown, in this cell type, that SR-BI is homogeneously distributed along the plasma membrane and consists principally of a non-raft membrane-associated pool. Raft destabilisation and caveolin-1 displacement from plasma membrane did not modify the SR-BI-mediated HDL-CE selective uptake. Moreover, the induction of SR-BI expression that is associated with increased CE selective uptake was not associated with any modification in caveolin-1 expression or any raft-targeting mechanism of SR-BI in NCI-H295R.
In conclusion, we provide evidence that SR-BI does not require raft/caveola localisation to be implicated in CE selective uptake either in basal or in induced conditions.

3.354 The uracil transporter Fur4p associates with lipid rafts
Hearn, J.D., Lester, R.L. and Dickson, R.C.
*J. Biol. Chem., **278**, 3679-3686 (2003)*

Sphingolipids are abundant components of eucaryotic membranes, where they perform essential functions. To uncover new roles for sphingolipids, we studied *Saccharomyces cerevisiae lcb1–100* cells, which have a temperature-sensitive block in the first step in sphingolipid synthesis. We find that the level of all five species of the sphingoid long chain base intermediates is reduced 2–7-fold in cells grown at a permissive temperature, and the level of complex sphingolipids is reduced 50%. In addition, *lcb1–100* cells make no detectable phosphorylated sphingoid bases. After transfer to a restrictive temperature (a heat shock), the level of the major sphingoid bases drops rather than transiently rising, as in wild type cells. These changes affect *lcb1–100* cells in multiple ways. Basal uracil transport by Fur4p is reduced 25%, and when cells are heat-shocked, uracil transport activity falls rapidly and is not restored as it is in wild type cells. Restoration requires a functional secretory pathway and synthesis of complex sphingolipids, leading us to hypothesize that Fur4p associates with lipid rafts. The finding that Fur4p is insoluble in TritonX-100 at 4 °C and behaves like a raft-associated protein on a density gradient supports this hypothesis. Raft association may be essential for regulating breakdown of Fur4p in response to stresses and other factors that govern uracil transport activity. Our results show that long chain bases do not contribute to the inactivation of Fur4p transport activity after heat stress, but they are essential for some later, but unknown, process that leads to degradation of the protein. Further studies using *lcb1–100* cells should reveal new roles of sphingolipids in nutrient uptake and other membrane-dependent processes.

3.355 Transient mechanoactivation of neutral sphingomyelinase in caveolae to generate ceramide
Czarny, M., Liu, J., Oh, P. and Schnitzer, J.E.
*J. Biol. Chem., **278**, 4424-4430 (2003)*

The vascular endothelium acutely autoregulates blood flow *in vivo* in part through unknown mechano-sensing mechanisms. Here, we report the discovery of a new acute mechanotransduction pathway. Hemodynamic stressors from increased vascular flow and pressure *in situ* rapidly and transiently induce the activity of neutral sphingomyelinase but not that acid sphingomyelinase in a time- and flow rate-dependent manner, followed by the generation of ceramides. This acute mechanoactivation occurs directly at the luminal endothelial cell surface primarily in caveolae enriched in sphingomyelin and neutral sphingo-myelinase, but not acid sphingomyelinase. Scyphostatin, which specifically blocks neutral but not acid sphingomyelinase, inhibits mechano-induced neutral sphingomyelinase activity as well as downstream activation of extracellular signalregulated kinase 1 and 2 (ERK1 and ERK2) by increased flow *in situ*. We postulate a novel physiological function for neutral sphingomyelinase as a new mechanosensor initiating the ERK cascade and possibly other mechanotransduction pathways.

3.356 Anthrax toxin triggers endocytosis of its receptor via a lipid raft-mediated clathrin-dependent process

Abrami, L., Liu, S., Cosson, P., Leppla, S.H. and van der Groot, F.G.
J. Cell Biol., ***160(3)****, 321-328 (2003)*

The protective antigen (PA) of the anthrax toxin binds to a cell surface receptor and thereby allows lethal factor (LF) to be taken up and exert its toxic effect in the cytoplasm. Here, we report that clustering of the anthrax toxin receptor (ATR) with heptameric PA or with an antibody sandwich causes its association to specialized cholesterol and glycosphingolipid-rich microdomains of the plasma membrane (lipid rafts). We find that although endocytosis of ATR is slow, clustering it into rafts either via PA heptamerization or using an antibody sandwich is necessary and sufficient to trigger efficient internalization and allow delivery of LF to the cytoplasm. Importantly, altering raft integrity using drugs prevented LF delivery and cleavage of cytosolic MAPK kinases, suggesting that lipid rafts could be therapeutic targets for drugs against anthrax. Moreover, we show that internalization of PA is dynamin and Eps15 dependent, indicating that the clathrin-dependent pathway is the major route of anthrax toxin entry into the cell. The present work illustrates that although the physiological role of the ATR is unknown, its trafficking properties, i.e., slow endocytosis as a monomer and rapid clathrin-mediated uptake on clustering, make it an ideal anthrax toxin receptor.

3.357 APH-1 I teracts with mature and immature forms of presenilins and nicastrin and may play a role in maturation of presenilin-nicastrin complexes

Gu, Y. et al
J. Biol. Chem., ***278(9)****, 7374-7380 (2003)*

APH-1 and PEN-2 genes modulate the function of nicastrin and the presenilins in *Caenorhabditis elegans*. Preliminary studies in transfected mammalian cells overexpressing tagged APH-1 proteins suggest that this genetic interaction is mediated by a direct physical interaction. Using the APH-1 protein encoded on human chromosome 1 (APH-1_1L; also known as APH-1a) as an archetype, we report here that endogenous forms of APH-1 are predominantly expressed in intracellular membrane compartments, including the endoplasmic reticulum and *cis*-Golgi. APH-1 proteins directly interact with immature and mature forms of the presenilins and nicastrin within high molecular weight complexes that display γ- and ε-secretase activity. Indeed APH-1 proteins can bind to the nicastrin Δ312-369 loss of function mutant, which does not undergo glycosylation maturation and is not trafficking beyond the endoplasmic reticulum. The levels of expression of endogenous APH-1_1L can be suppressed by overexpression of any other members of the APH-1 family, suggesting that their abundance is coordinately regulated. Finally, although the absence of APH-1 destabilizes the presenilins, in contrast to nicastrin and PEN-2, APH-1 itself is only modestly destabilized in cells lacking functional expression of presenilin 1 or presenilin 2. Taken together, our data suggest that APH-1 proteins, and APH-1_1 in particular, may have a role in the initial assembly and maturation of presenilin·nicastrin complexes.

3.358 Dynamin-like protein 1 is involved in peroxisomal fission

Koch, A. et al
J. Biol. Chem., ***278(10)****, 8597-8605 (2003)*

The mammalian dynamin-like protein 1 (DLP1), a member of the dynamin family of large GTPases, possesses mechanochemical properties known to constrict and tubulate membranes. In this study, we have combined two experimental approaches, induction of peroxisome proliferation by Pex11pβ and expression of dominant-negative mutants, to test whether DLP1 plays a role in peroxisomal growth and division. We were able to localize DLP1 in spots on tubular peroxisomes in HepG2 cells. In addition, immunoblot analysis revealed the presence of DLP1 in highly purified peroxisomal fractions from rat liver and an increase of DLP1 after treatment of rats with the peroxisome proliferator bezafibrate. Expression of a dominant negative DLP1 mutant deficient in GTP hydrolysis (K38A) either alone or in combination with Pex11pβ caused the appearance of tubular peroxisomes but had no influence on their intracellular distribution. In co-expressing cells, the formation of tubulo-reticular networks of peroxisomes was promoted, and peroxisomal division was completely inhibited. These findings were confirmed by silencing of DLP1 using siRNA. We propose a direct role for the dynamin-like protein DLP1 in peroxisomal fission and in the maintenance of peroxisomal morphology in mammalian cells.

3.359 Oligomeric and polymeric aggregates formed by proteins containing expanded polyglutamine
Iuchi, S., Hoffner, G., Verbeke, P., Djian, P. And Green, H.
*PNAS, **100(5)**, 2409-2414 (2003)*

Neurological diseases resulting from proteins containing expanded polyglutamine (polyQ) are characteristic-ally associated with insoluble neuronal inclusions, usually intranuclear, and neuronal death. We describe here oligomeric and polymeric aggregates formed in cells by expanded polyQ. These aggregates are not dissocia-ted by concentrated formic acid, an extremely effective solvent for otherwise insoluble proteins. Perinuclear inclusions formed in cultured cells by expanded polyQ can be completely dissolved in concentrated formic acid, but a soluble protein oligomer containing the expanded polyQ and released by the formic acid is not dissociated to monomer. In Huntington's disease, a formic acid-resistant oligomer is present in cerebral cort-ex, but not in cerebellum. Cortical nuclei contain a polymeric aggregate of expanded polyQ that is insoluble in formic acid, does not enter polyacrylamide gels, but is retained on filters. This finding shows that the process of polymerization is more advanced in the cerebral cortex than in cultured cells. The resistance of oligomer and polymer to formic acid suggests the participation of covalent bonds in their stabilization.

3.360 Influenza B virus BM2 protein is an oligomeric integral membrane protein expressed at the cell surface
Paterson, R.G., Takeda, M., Ohigashi, Y., Pinto, L.H. and Lamb, R.A.
*Virology, **306**, 7-17 (2003)*

The influenza B virus BM2 protein contains 109 amino acid residues and it is translated from a bicistronic mRNA in an open reading frame that is +2 nucleotides with respect to the matrix (M1) protein. The amino acid sequence of BM2 contains a hydrophobic region (residues 7–25) that could act as a transmembrane (TM) anchor. Analysis of properties of the BM2 protein, including detergent solubility, insolubility in alkali pH 11, flotation in membrane fractions, and epitope-tagging immunocytochemistry, indicates BM2 protein is the fourth integral membrane protein encoded by influenza B virus in addition to hemagglutinin (HA), neuraminidase (NA), and the NB glycoprotein. Biochemical analysis indicates that the BM2 protein adopts an $N_{out}C_{in}$ orientation in membranes and fluorescence microscopy indicates BM2 is expressed at the cell surface. As the BM2 protein possesses only a single hydrophobic domain and lacks a cleavable signal sequ-ence, it is another example of a Type III integral membrane protein, in addition to M_2, NB, and CM2 prot-eins of influenza A, B, and C viruses, respectively. Chemical cross-linking studies indicate that the BM2 protein is oligomeric, most likely a tetramer. Comparison of the amino acid sequence of the TM domain of the BM2 protein with the sequence of the TM domain of the proton-selective ion channel M_2 protein of influenza A virus is intriguing as M_2 protein residues critical for ion selectivity/activation and channel gating (H^{37} and W^{41}, respectively) are found at the same relative position and spacing in the BM2 protein (H^{19} and W^{23}).

3.361 Mammalian Ykt6 is a neuronal SNARE targeted to a specialized compartment by its profilin-like amino terminal domain
Hasegawa, H. et al
*Mol. Biol. Cell, **14**, 698-720 (2003)*

SNAREs are required for specific membrane fusion throughout the endomembrane system. Here we report the characterization of rat ykt6, a prenylated SNARE selectively expressed in brain neurons. Immunofluor-escence microscopy in neuronal and neuroendocrine cell lines revealed that membrane-associated ykt6 did not colocalize significantly with any conventional markers of endosomes, lysosomes, or the secretory path-way. However, ykt6-containing membranes displayed very minor overlaps with lysosomes and dense-core secretory granules and were similar to lysosomes in buoyant density. Thus, ykt6 appears to be specialized for the trafficking of a unique membrane compartment, perhaps related to lysosomes, involved in aspects of neuronal function. Targeting of this SNARE to the ykt6 compartment was mediated by its profilin-like amino-terminal domain, even in the absence of protein prenylation. Although several other R-SNAREs contain related amino-terminal domains, only the ykt6 version was able to confer the specialized localiz-ation. Rat ykt6, which contains an arginine in its SNARE motif zero-layer, was found to behave like other R-SNAREs in its SNARE assembly properties. Interestingly, cytosolic ykt6, constituting more than half of the total cellular pool, appeared to be conformationally inactive for SNARE complex assembly, perhaps

indicative of a regulatory mechanism that prevents promiscuous and potentially deleterious SNARE interactions.

3.362 Inhibitors of glycosphingolipid biosynthesis reduce transepithelial electrical resistance in MDCK I and FRT cells

Leung, L.W., Contreras, R.G., Flores-Maldomado, C., Cereijido, M. and Rodriguez-Boulan, E.
*Am. J. Physiol. Cell Physiol., **284**, C1021-C1030 (2003)*

Madin-Darby canine kidney (MDCK) I and Fisher rat thyroid (FRT) cells exhibit transepithelial electrical resistance (TER) values in excess of 5,000 $\Omega \cdot cm^2$. When these cells were incubated in the presence of various inhibitors of sphingolipid biosynthesis, a >5-fold reduction of TER was observed without changes in the gate function for uncharged solutes or the fence function for apically applied fluorescent lipids. The localization of ZO-1 and occludin was not altered between control and inhibitor-treated cells, indicating that the tight junction was still intact. Furthermore, the complexity of tight junction strands, analyzed by freeze-fracture microscopy, was not reduced. Once the inhibitor was removed and the cells were allowed to synthesize sphingolipids, a gradual recovery of the TER was observed. Interestingly, these inhibitors did not attenuate the TER of MDCK II cells, a cell line that typically exhibits values below 800 $\Omega \cdot cm^{2.}$ These results suggest that glycosphingolipids play a role in regulating the electrical properties of epithelial cells.

3.363 Regulatory volume decrease in *Trypanosoma cruzi* involves amoni acid efflux and changes in intracellular calcium

Rohloff, P., Rodrigues, C.O. and Dacompo, R.
*Mol. Biochem. Parasit., **126**, 219-230 (2003)*

A regulatory volume decrease (RVD) in response to hyposmotic stress has been characterized in different life-cycle stages of *Trypanosoma cruzi*. Hyposmotic stress initially caused swelling, but this was rapidly reversed by a compensatory volume reversal that was essentially complete by 5 min. Volume recovery was associated with an amino acid efflux that accounted for approximately 50% of the regulatory volume decrease in all three life-cycle stages. The amino acid efflux was selective for neutral and anionic amino acids, but excluded cationic amino acids. Acidocalcisomes contained an amino acid pool over four times more concentrated than whole-cell levels, but about 90% of this was composed of Arg and Lys, so involvement of this pool in amino acid efflux was ruled out. Hyposmotic stress induced a rise in intracellular calcium that was dependent on influx of calcium across the plasma membrane, since chelation of extracellular calcium abolished the response. Influx of calcium was confirmed by demonstration of manganese-mediated quenching of intracellular fura-2 fluorescence and partial inhibition of the rise in calcium by calcium channel blockers. Manipulation of intra- and extracellular calcium levels had minor effects on the initial rate of amino acid efflux and no effect on the rate of volume recovery.

3.364 Caveolar compartmentation of caspase-3 in cardiac endothelial cells

Oxhorn, B.C. and Buxton, I.L.O.
*Cellular Signalling, **15**, 489-496 (2003)*

Endothelial cell apoptosis is intimately involved in the balance between blood vessel growth and regression and is promoted by numerous stimuli including angiostatin and endostatin, reactive oxygen species (ROS) released during inflammatory processes, and chronic use of drugs of abuse such as cocaine. Apoptosis is characterized by many biological signalling events, including the activation of caspases. Caveolar domains have been hypothesized to mediate apoptotic signalling. We have addressed this hypothesis in cardiac endothelial cells and here we show that caspase-3 proenzyme (32 kDa) and its activated counterpart (17 kDa) co-purify with low-density, caveolin-enriched microdomains and that caspase-3 can be localized with caveolae in intact cells using fluorescent microscopy. Disruption of caveolae results in temporal and spatial changes in enzyme activity. While caspase-3 has been associated with mitochondrial, cytosolic, and high-density regions, the co-purification of activated caspase-3 and caveolar domains reported here suggests the possibility that sarcolemmal caspase-3 may be targeted to plasma-membrane associated substrates.

3.365 Rapid localization of Gag/GagPol Complexes to detergent-resistant membrane during the assembly of human immunodeficiency virus type 1
Halwani, R., Khorchid, A., Cen, S. and Kleiman, L
*J. Virol., **77(7)**, 3973-3984 (2003)*

During human immunodeficiency virus type 1 (HIV-1) assembly in HIV-1-transfected COS7 cells, almost all steady-state Gag/Gag and Gag/GagPol complexes are membrane bound. However, exposure to 1% Triton X-100 gives results indicating that while all Gag/GagPol complexes remain associated with the detergent-resistant membrane (DRM), only 30% of Gag/Gag complexes are associated with the DRM. Analysis of the localization of newly synthesized Gag/Gag and Gag/GagPol to the membrane indicates that after a 10-min pulse with radioactive [^{35}S]Cys-[^{35}S]Met, all newly synthesized Gag/GagPol is found at the DRM. Only 30% of newly synthesized Gag/Gag moves to the membrane, and at 0 min of chase, only 38% of this membrane-bound Gag/Gag is associated with the DRM. During the first 30 min of chase, most membrane-bound Gag/Gag moves to the DRM, while between 30 and 60 min of chase, there is a significant decrease in membrane-bound Gag/Gag and Gag/GagPol. Since the localization of newly synthesized Gag/Gag to the DRM and the interaction of GagPol with Gag both depend upon Gag multimerization, the rapid localization of GagPol to the DRM probably reflects the interaction of all newly synthesized GagPol with the first newly synthesized polymeric Gag to associate with the DRM.

3.366 Localization of presenilin-nicastrin complexes and γ-secretase activity to the *trans*-Golgi network
Siman, R. and Velji, J.
*J. Neurochem., **84**, 1143-1153 (2003)*

Abundant biochemical and genetic evidence suggests that presenilins are catalytic components of γ-secretase, the protease responsible for generating the Alzheimer amyloid ß-protein. However, the differential localization of presenilins to early secretory compartments and γ-secretase substrates to late secretory compartments and the plasma membrane (the 'spatial paradox') argues against this view. We investigated this issue by studying the localization of nicastrin, another putative γ-secretase component, and its association with presenilin-1 into proteolytically active complexes. Glycosidase digests revealed that nicastrin exists in multiple glycoforms and is terminally sialylated, a modification often associated with the *trans* -Golgi network. Trafficking of nicastrin to the *trans* -Golgi network was confirmed by density gradient fractionation and immunofluorescence microscopy. In presenilin-deficient cells, however, nicastrin trafficking and maturation were abnormal, as the protein was restricted to early secretory compartments and failed to be sialylated. Mature sialylated nicastrin in *trans* -Golgi network fractions was complexed quantitatively with N- and C-terminal fragments of presenilin-1, whereas immature nicastrin present in early secretory compartments was not. Additionally, *trans* -Golgi network fractions contained the γ-secretase substrate ß-amyloid precursor protein C83 and were enriched in presenilin-dependent γ-secretase proteolytic activity. The results resolve the apparent spatial paradox by demonstrating that presenilin–nicastrin complexes and presenilin-dependent γ-secretase activity are co-localized to a late secretory compartment. The findings provide further evidence that presenilin-containing complexes are the γ-secretase, and indicate that presenilins also regulate γ-secretase assembly.

3.367 Do lipid raft mediate virus assembly and pseudotyping?
Briggs, J.A., Wilk, T. and Fuller, S.D.
*J. Gen. Virol., **84**, 757-768 (2003)*

Co-infection of a host cell by two unrelated enveloped viruses can lead to the production of pseudotypes: virions containing the genome of one virus but the envelope proteins of both viruses. The selection of components during virus assembly must therefore be flexible enough to allow the incorporation of unrelated viral membrane proteins, yet specific enough to exclude the bulk of host proteins. This apparent contradiction has been termed the pseudotypic paradox. There is mounting evidence that lipid rafts play a role in the assembly pathway of non-icosahedral, enveloped viruses. Viral components are concentrated initially in localized regions of the plasma membrane via their interaction with lipid raft domains. Lateral interactions of viral structural proteins amplify the changes in local lipid composition which in turn enhance the concentration of viral proteins in the rafts. An affinity for lipid rafts may be the common feature of enveloped virus proteins that leads to the formation of pseudotypes.

3.368 Mastoparan selectively activates phospholipase D2 in cell membranes
Chahdi, A., Choi, W.S., Kim, Y. M. and Beaven, M.A.

J. Biol. Chem., ***278(14)***, *12039-12045 (2003)*

Both known isoforms of phospholipase (PL) D, PLD1 and PLD2, require phosphatidylinositol 4,5-bisphosphate for activity. However, PLD2 is fully active in the presence of this phospholipid, whereas PLD1 activation is dependent on additional factors such as ADP-ribosylation factor-1 (ARF-1) and protein kinase Cα. We find that mastoparan, an activator of G_i and mast cells, stimulates an intrinsic PLD activity, most likely PLD2, in fractions enriched in plasma membranes from rat basophilic leukemia 2H3 mast cells. Overexpression of PLD2, but not of PLD1, results in a large increase in the mastoparan-inducible PLD activity in membrane fractions, particularly those enriched in plasma membranes. As in previous studies, expressed PLD2 is localized primarily in the plasma membrane and PLD1 in granule membranes. Studies with pertussis toxin and other agents indicate that mastoparan stimulates PLD2 independently of G_i, ARF-1, protein kinase C, and calcium. Kinetic studies indicate that mastoparan interacts synergistically with phosphatidylinositol 4,5-bisphosphate and that oleate, itself a weak stimulant of PLD2 at low concentrations, is a competitive inhibitor of mastoparan stimulation of PLD2. Therefore, mastoparan may be useful for investigating the regulation of PLD2, particularly in view of the well studied molecular interactions of mastoparan with certain other strategic signaling proteins.

3.369 Human immunodeficiency virus type 1 assembly and lipid rafts: Pr55^{gag} associates with membrane domains

Holm, K., Weclewicz,K., Hewson, R. and Suomalainen, M.
*J. Virol.,**77**, 4805-4817 (2003)*

The assembly and budding of human immunodeficiency virus type 1 (HIV-1) at the plasma membrane are directed by the viral core protein Pr55^{gag}. We have analyzed whether Pr55^{gag} has intrinsic affinity for sphingolipid- and cholesterol-enriched raft microdomains at the plasma membrane. Pr55^{gag} has previously been reported to associate with Triton X-100-resistant rafts, since both intracellular membranes and virus-like Pr55^{gag} particles (VLPs) yield buoyant Pr55^{gag} complexes upon Triton X-100 extraction at cold temperatures, a phenotype that is usually considered to indicate association of a protein with rafts. However, we show here that the buoyant density of Triton X-100-treated Pr55^{gag} complexes cannot be taken as a proof for raft association of Pr55^{gag}, since lipid analyses of Triton X-100-treated VLPs demonstrated that the detergent readily solubilizes the bulk of membrane lipids from Pr55^{gag}. However, Pr55^{gag} might nevertheless be a raft-associated protein, since confocal fluorescence microscopy indicated that coalescence of GM1-positive rafts at the cell surface led to copatching of membrane-bound Pr55^{gag}. Furthermore, extraction of intracellular membranes or VLPs with Brij98 yielded buoyant Pr55^{gag} complexes of low density. Lipid analyses of Brij98-treated VLPs suggested that a large fraction of the envelope cholesterol and phospholipids was resistant to Brij98. Collectively, these results suggest that Pr55^{gag} localizes to membrane microdomains that are largely resistant to Brij98 but sensitive to Triton X-100, and these membrane domains provide the platform for assembly and budding of Pr55^{gag} VLPs.

3.370 Regulation of cytochrome c oxidase activity by c-Src in osteoclasts

Miyazaki, T., Neff, L., Tanaka, S., Horne, W.C. and Baron, R.
J. Cell Biol., ***160(5)***, *709-718 (2003)*

The function of the nonreceptor tyrosine kinase c-Src as a plasma membrane–associated molecular effector of a variety of extracellular stimuli is well known. Here, we show that c-Src is also present within mitochondria, where it phosphorylates cytochrome *c* oxidase (Cox). Deleting the c-*src* gene reduces Cox activity, and this inhibitory effect is restored by expressing exogenous c-Src. Furthermore, reducing endogenous Src kinase activity down-regulates Cox activity, whereas activating Src has the opposite effect. Src-induced Cox activity is required for normal function of cells that require high levels of ATP, such as mitochondria-rich osteoclasts. The peptide hormone calcitonin, which inhibits osteoclast function, also down-regulates Cox activity. Increasing Src kinase activity prevented the inhibitory effect of calcitonin on Cox activity and osteoclast function. These results suggest that c-Src plays a previously unrecognized role in maintaining cellular energy stores by activating Cox in mitochondria.

3.371 Peroxisomal membrane monocarboxylate transporters: evidence for a redox shuttle system
McClelland, G.B., Khanna, S., Gonzales, G.F., Butz, C.E. and Brooks, G.A.
*Biochem. Biophys. Res. Comm., **304**, 130-135 (2003)*

One of the many functions of liver peroxisomes is the β-oxidation of long-chain fatty acids. It is essential for the continuation of peroxisomal β-oxidation that a redox shuttle system exist across the peroxisomal membrane to reoxidize NADH. We propose that this redox shuttle system consists of a substrate cycle between lactate and pyruvate. Here we present evidence that purified peroxisomal membranes contain both monocarboxylate transporter 1 (MCT 1) and MCT 2 and that along with peroxisomal lactate dehydrogenase (pLDH) form a Peroxisomal Lactate Shuttle. Peroxisomal β-oxidation was greatly stimulated by the addition of pyruvate and this increase was partially inhibited by the addition of the MCT blocker α-cyano-4-hydroxycinnamate (CINN). We also found that peroxisomes generated lactate in the presence of pyruvate. Together these data provide compelling that the Peroxisome Lactate Shuttle helps maintain organelle redox and the proper functioning of peroxisomal β-oxidation.

3.372 Modulation of Rho GTPase signaling regulates a switch between adigenesis and myogenesis
Sordella, R. et al
*Cell, **113**, 147-158 82003)*

Mature adipocytes and myocytes are derived from a common mesenchymal precursor. While IGF-1 promotes the differentiation of both cell types, the signaling pathways that specify the distinct cell fates are largely unknown. Here, we show that the Rho GTPase and its regulator, p190-B RhoGAP, are components of a critical switch in the adipogenesis-myogenesis "decision." Cells derived from embryos lacking p190-B RhoGAP exhibit excessive Rho activity, are defective for adipogenesis, but undergo myogenesis in response to IGF-1 exposure. In vitro, activation of Rho-kinase by Rho inhibits adipogenesis and is required for myogenesis. The activation state of Rho following IGF-1 signaling is determined by the tyrosine-phosphorylation status of p190-B RhoGAP and its resulting subcellular relocalization. Moreover, adjusting Rho activity is sufficient to alter the differentiation program of adipocyte and myocyte precursors. Together, these results identify the Rho GTPase as an essential modulator of IGF-1 signals that direct the adipogenesis-myogenesis cell fate decision.

3.373 The SNARE motif contributes to rbet1 intracellular targeting and dynamics independently of SNARE interactions
Joglekar, A.P., Xu, D., Rigotti, D.J., Fairman, R. and Hay, J.C.
*J. Biol. Chem., **278(16)**, 14121-14133 (2003)*

The endoplasmic reticulum/Golgi SNARE rbet1 cycles between the endoplasmic reticulum and Golgi and is essential for cargo transport in the secretory pathway. Although the quaternary SNARE complex containing rbet1 is known to function in membrane fusion, the structural role of rbet1 is unclear. Furthermore, the structural determinants for rbet1 targeting and its cyclical itinerary have not been investigated. We utilized protein interaction assays to demonstrate that the rbet1 SNARE motif plays a structural role similar to the carboxyl-terminal helix of SNAP-25 in the synaptic SNARE complex and demonstrated the importance to SNARE complex assembly of a conserved salt bridge between rbet1 and sec22b. We also examined the potential role of the rbet1 SNARE motif and SNARE interactions in rbet1 localization and dynamics. We found that, in contrast to what has been observed for syntaxin 5, the rbet1 SNARE motif was essential for proper targeting. To test whether SNARE interactions were important for the targeting function of the SNARE motif, we used charge repulsion mutations at the conserved salt bridge position that rendered rbet1 defective for binary, ternary, and quaternary SNARE interactions. We found that heteromeric SNARE interactions are not required at any step in rbet1 targeting or dynamics. Furthermore, the heteromeric state of the SNARE motif does not influence its interaction with the COPI coat or efficient recruitment onto transport vesicles. We conclude that protein targeting is a completely independent function of the rbet1 SNARE motif, which is capable of distinct classes of protein interactions.

3.374 Effect of glycosylphosphatidylinositol anchor-dependent and -independent prion protein association with model raft membranes on conversion to the protease-resistant isoform

Baron, G.S. and Caughey, B.

J. Biol. Chem., ***278(17)***, *14883-14892 (2003)*

Prion protein (PrP) is usually bound to membranes by a glycosylphosphatidylinositol (GPI) anchor that associates with detergent-resistant membranes, or rafts. To examine the effect of membrane association on the interaction between the normal protease-sensitive PrP isoform (PrP-sen) and the protease-resistant isoform (PrP-res), a model system was employed using PrP-sen reconstituted into sphingolipid-cholesterol-rich raft-like liposomes (SCRLs). Both full-length (GPI^+) and GPI anchor-deficient (GPI^-) PrP-sen produced in fibroblasts stably associated with SCRLs. The latter, alternative mode of membrane association was not detectably altered by glycosylation and was markedly reduced by deletion of residues 34-94. The SCRL-associated PrP molecules were not removed by treatments with either high salt or carbonate buffer. However, only GPI^+ PrP-sen resisted extraction with cold Triton X-100. PrP-sen association with SCRLs was pH-independent. PrP-sen was also one of a small subset of phosphatidylinositol-specific phospholipase C (PI-PLC)-released proteins from fibroblast cells found to bind SCRLs. A cell-free conversion assay was used to measure the interaction of SCRL-bound PrP-sen with exogenous PrP-res as contained in microsomes. SCRL-bound GPI^+ PrP-sen was not converted to PrP-res until PI-PLC was added to the reaction or the combined membrane fractions were treated with the membrane-fusing agent polyethylene glycol (PEG). In contrast, SCRL-bound GPI^- PrP-sen was converted to PrP-res without PI-PLC or PEG treatment. Thus, of the two forms of raft membrane association by PrP-sen, only the GPI anchor-directed form resists conversion induced by exogenous PrP-res.

3.375 Plasma membrane rafts of rainbow trout are subject to thermal acclimation

Zehmer, J.K. and Hazel, J.R.

J. Exp. Biol., ***206***, *1657-1667 (2003)*

Rafts are cholesterol- and sphingolipid-enriched microdomains of the plasma membrane (PM) that organize many signal transduction pathways. Interactions between cholesterol and saturated lipids lead to patches of liquid-ordered membrane (rafts) phase-separating from the remaining PM. Phase behavior is temperature sensitive, and acute changes in temperature experienced by poikilotherms would be expected to perturb raft structure, necessitating an acclimatory response. Therefore, with thermal acclimation, we would expect compositional changes in the raft directed to offset this perturbation. Using differential and density gradient centrifugation, we separated PM from the livers of rainbow trout acclimated to 5°C and 20°C into raft-enriched (raft) and raft-depleted PM (RDPM). Compared with RDPM, the raft fractions were enriched in cholesterol, the $ß_2$-adrenergic receptor and adenylyl cyclase, which are commonly used markers for this microdomain. Furthermore, cholesterol was enriched in all fractions from warm-compared with cold-acclimated animals, but this increase was 3.4 times greater in raft than in PM. We developed a novel approach for measuring membrane molecular interaction strength (and thus the tendency to stabilize raft structure) based on the susceptibility of membranes to detergent. Specifically, studies with model vesicles demonstrated that the capacity of a membrane to accommodate detergent prior to solubilization (saturation point) was a good index of this property. The saturation point of the isolated membrane preparations was temperature sensitive and was significantly different in 5°C- and 20°C-acclimated RDPM when assayed at 5°C and 20°C, respectively. By contrast, this comparison in rafts was not significantly different, suggesting compensation of this property. These data suggest that compositional changes made in the PM during thermal acclimation act to offset thermal perturbation of the raft but not the RDPM structural integrity.

3.376 **Ligand-dependent recruitment of the ErbB4 signaling complex into neuronal lipid rafts**
Li Ma et al
J. Neurosci., ***23(8)***, *3164-3175 (2003)*

Neuregulin (NRG) regulates synapse formation and synaptic plasticity, but little is known about the regulation of NRG signaling at synapses. Here we show that the NRG receptor ErbB4 was localized in anatomically defined postsynaptic densities in the brain. In cultured cortical neurons, ErbB4 was recruited to the neuronal lipid raft fraction after stimulation by NRG. Along with ErbB4, adaptor proteins Grb2 and Shc were translocated to lipid rafts by NRG stimulation. In transfected human embryonic kidney 293 cells, the partitioning of ErbB4 into a detergent-insoluble fraction that includes lipid rafts was increased by PSD-95 (postsynaptic density-95), through interaction of the ErbB4 C terminus with the PDZ [PSD-95/Discs large/zona occludens-1] domains of PSD-95. Disruption of lipid rafts inhibited NRG-induced activation of Erk and prevented NRG-induced blockade of induction of long-term potentiation at hippocampal CA1 synapses. Thus, our results indicate that NRG stimulation causes translocation of ErbB4 into lipid rafts and that lipid rafts are necessary for signaling by ErbB4.

3.377 **Raft partitioning of the yeast uracil permease during trafficking along the endocytic pathway**
Dupre, S. and Haguenauer-Tsapis, R.
Traffic, ***4***, *83-96 (2003)*

Lipid rafts, formed by the lateral association of sphingolipids and cholesterol in the external membrane leaflet, have been implicated in membrane traffic and cell signaling in mammalian cells. Yeast plasma membranes were also recently shown to contain lipid raft microdomains consisting of sphingolipids and ergosterol, and containing several plasma membrane proteins, including Gas1p, a GPI-anchored protein, and the [H^+] ATPase Pma1p. In this study, we investigated whether lipid rafts were involved in the intracellular trafficking of a yeast transporter, uracil permease, which undergoes ubiquitin-dependent endocytosis. Regardless of its ubiquitination status, uracil permease was found to be associated with rafts in the plasma membrane. The expression of Fur4p in *lcb1-100* cells, deficient in the first enzyme of sphingolipid synthesis, impaired the association of Fur4p with detergent-resistant fractions. When targeted to endocytic compartments, uracil permease appeared to be progressively transferred to detergent-soluble fractions, suggesting that the lipid environment might change between plasma membrane and endosomes. Consistent with this hypothesis, the wild-type form of the v-SNARE Snc1p, which is known to cycle between the plasma membrane and endosomal compartments, was recovered in both detergent-resistant and detergent-soluble fractions. In contrast, a variant Snc1p that accumulates at the plasma membrane was recovered exclusively in detergent-resistant fractions.

3.378 **The structure of murine outer segment disk membranes using atomic force microscopy**
Saperstein, D.A. et al
Invest. Ophthalmol Vis. Sci., ***44***, *E-abstract 3175 (2003)*

Purpose: Atomic force microscopy (AFM) is a powerful new tool to study biologic membranes. We used AFM to study the surface of murine rod outer segment disk membranes
Methods: Dark adapted wildtype C57BL/6 mice were sacrificed and their retinas were removed. Osmotically intact rod outer segments (ROS) were isolated via centrifugation in an **Optiprep** gradient. The ROS were then burst using 2mM Tris-HCl, pH 7.4, at 0°C for 15 hr and isolated using centrifugation in an **Optiprep** gradient. The isolated disks were adsorbed to mica and scanned using a Nanoscope Multimode microscope (Digital Instruments) equipped with an infrared laser head, fluid cell, and oxide-sharpened silicon nitride cantilevers (OMCL-TR400PSA, Olympus) in aqueous fluid using the contact scanning mode. All procedures were carried out in complete darkness with the aid of night vision goggles. The disk integrity was verified by scanning and transmission electron microscopy.
Results: The superstructure of the disk membrane was revealed. The cytoplasmic surface of the disks are textured and under high magnification consist of rows of rhodopsin pairs densely packed in paracrystalline arrays. The density of rhodopsin monomers averages 48,300 molecules per μm^2. The distance measured between rhodopsin molecules in the dimer was 3.8 nm (N=40). This measurement was consistent with measurements using the angularly averaged powder diffraction pattern.
Conclusions: This study represents the first description of the higher order structure of rhodopsin molecules within the native disk membranes. The resolution is sufficient to visualize individual unstained rhodpsin molecules. The dimeric nature of rhodopsin in the disk membrane is clearly demonstrated supporting published pharmacological and biochemical analyses.

3.379 Amphipathic helix-dependent localization of NS5A mediates hepatitis C virus RNA replication
Elazar, M. et al
*J. Virol., **77(10)**, 6055-6061 (2003)*

We identified an N-terminal amphipathic helix (AH) in one of hepatitis C virus (HCV)'s nonstructural proteins, NS5A. This AH is necessary and sufficient for membrane localization and is conserved across isolates. Genetically disrupting the AH impairs HCV replication. Moreover, an AH peptide-mimic inhibits the membrane association of NS5A in a dose-dependent manner. These results have exciting implications for the HCV life cycle and novel antiviral strategies.

3.380 Role of caveolae in signal-tranducing function of cardiac Na^+/K^+ -ATPase
Liu, L. et al
*Am. J. Physiol. Cell Physiol., **284**, C1550-C1560 (2003)*

Ouabain binding to Na^+/K^+-ATPase activates Src/epidermal growth factor receptor (EGFR) to initiate multiple signal pathways that regulate growth. In cardiac myocytes and the intact heart, the early ouabain-induced pathways that cause rapid activations of ERK1/2 also regulate intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) and contractility. The goal of this study was to explore the role of caveolae in these early signaling events. Subunits of Na^+/K^+-ATPase were detected by immunoblot analysis in caveolae isolated from cardiac myocytes, cardiac ventricles, kidney cell lines, and kidney outer medulla by established detergent-free procedures. Isolated rat cardiac caveolae contained Src, EGFR, ERK1/2, and 20-30% of cellular contents of α_1- and α_2-isoforms of Na^+/K^+-ATPase, along with nearly all of cellular caveolin-3. Immunofluorescence microscopy of adult cardiac myocytes showed the presence of caveolin-3 and α-isoforms in peripheral sarcolemma and T tubules and suggested their partial colocalization. Exposure of contracting isolated rat hearts to a positive inotropic dose of ouabain and analysis of isolated cardiac caveolae showed that ouabain caused *1*) no change in total caveolar ERK1/2, but a two- to threefold increase in caveolar phosphorylated/activated ERK1/2; *2*) no change in caveolar α_1-isoform and caveolin-3; and *3*) 50-60% increases in caveolar Src and α_2-isoform. These findings, in conjunction with previous observations, show that components of the pathways that link Na^+/K^+-ATPase to ERK1/2 and $[Ca^{2+}]_i$ are organized within cardiac caveolae microdomains. They also suggest that ouabain-induced recruitments of Src and α_2-isoform to caveolae are involved in the manifestation of the positive inotropic effect of ouabain.

3.381 Resistance of cell membranes to different antigens
Schuck, S., Honsho, M., Ekroos, K., Shevchenko, A. and Simons, K.
*Proc. Natl. Acad. Sci. USA, **100**, 5795-5800 (2003)*

Partial resistance of cell membranes to solubilization with mild detergents and the analysis of isolated detergent-resistant membranes (DRMs) have been used operationally to define membrane domains. Given the multitude of detergents used for this purpose. we sought to investigate whether extraction with different deter gents might reflect the same underlying principle of domain formation. We therefore compared the protein and lipid content of DRM5 prepared with a variety of detergents from two cell lines. We found that the detergents differ considerably in their ability to selectively solubilize membrane proteins and to enrich sphingolipids and cholesterol over glycerophospholipids as well as saturated over unsaturated phosphatidyicholine. In addition, we observed cell type-dependent variations of the molecular characteristics of DRMs and the effectiveness of particular detergents. These results make it unlikely that different detergents reflect the same aspects of membrane organization and underscore both the structural complexity of cell membranes and the need for more sophisticated analytical tools to understand their architecture.

3.382 Nephrin and Neph1 co-localize at the podocyte foot process intercellular junction and form *cis* hetero-oligomers

Barletta, G-M., Kovari, I.A., Verma, R.K., Kerjaschki, D. and Holzmann, L.B.
J. Biol. Chem., ***278***, *19266-19271 (2003)*

Glomerular visceral epithelial cells (podocytes) appear to play a central role in maintaining the selective filtration barrier of the renal glomerulus. While the immunoglobulin superfamily member Nephrin was proposed to act as a cell adhesion molecule at the podocyte intercellular junction necessary for maintaining gbmerular perm selectivity, the Nephrin ligand has not been identified. The existence of a new subfamily of Nephrin-like molecules including Neph1 was recently described. Genetic deletion of Nephrin or Neph1 resulted in similar phenotypes of podocyte foot process effacement and proteinuria. The subcellular localization of Neph1 and the possibility that Nephrin and Neph1 interact was investigated. Polyclonal antiserum for Neph1 was raised and characterized. Neph1 migrated as a 90-kDa protein on SDS-PAGE under reducing conditions. Neph1 was identified in a glomerular and podocyte-specific distribution in adult rat kidney. Like Nephrin and Podocin, Neph1 was enriched in Triton X-100 detergent-resistant membrane fractions. Consistent with this observation, immunogold electron microscopy demonstrated that Neph1 localized exclusively to lateral margins of podocyte foot processes at the insertion of the slit diaphragm. Neph1 and Nephrin participate in a direct cis-interaction involving their cytoplasmic domains. In addition, interactions between the extracellular domain of Nephrin and itself and between the extracellular domain of Nephrin and that of Neph1 were detected. Neph1 did not interact via a homophilic interaction. These observations suggest that Nephrin and Neph1 form a hetero-oligomeric receptor complex in the plane of the membrane that might interact across the foot process intercellular junction through interactions between Nephrin with itself and Neph1.

3.383 Distinct rates of palmitate turnover on membrane-bound cellular and oncogenic H-Ras

Baker, T.L., Zheng, H., Walker, J., Coloff, J.L. and Buss, J.E.
J. Biol. Chem., ***278***, *19292-19300 (2003)*

H-Ras displays dynamic cycles of GTP binding and palmitate turnover. GTP binding is clearly coupled to activation, but whether the palmitoylated COOH terminus participates in signaling, especially when constrained by membrane tethering, is unknown. As a way to compare COO!! termini of membrane-bound, lipid-modified H-Ras, palmitate removal rates were measured for various forms of H-Ras in NIH 3T3 cells. Depalmitoylation occurred slowly (t_2 ~2.4 h) in cellular (H-RasWT) or dominant negative (H-Rasl7N) forms and more rapidly (t_2 ~1 h) in oncogenic H-Ras6lL or H-RasRl2,T59. Combining this data with GTP binding measurements, the palmitate half-life of H-Ras in the fully GTP-bound state was estimated to be less than 10 min. Slow palmitate removal from cellular H-Ras was not explained by sequestration in caveolae, as neither cellular nor oncogenic H-Ras showed alignment with caveolin by immunofluorescence. Conversely, although it had faster palmitate removal, oncogenic H-Ras was located in the same fractions as H-RasWT on four types of density gradients, and remained fully membrane-bound. Thus the different rates of deacylation occurred even though oncogenic and cellular H-Has appeared to be in similar locations. Instead, these results suggest that acyiprotein thioesterases access oncogenic H-Ras more easily because the conformation of its COOH terminus against the membrane is altered. This previously undetected difference could help produce distinctive effector interactions and signaling of oncogenic H-Ras.

3.384 Palmitoylation regulates regulators of G-protein signaling (RGS) 16 function: I Mutation of amino-terminalcysteine residues on RGS16 prevents its targeting to lipid rafts and palmitoylation of an internal cysteine residue.

Hiol, A et al

J. Biol. Chem., ***278***, *19301-19308 (2003)*

Regulators of G-protein signaling (RGS) proteins down-regulate signaling by heterotrimeric G-proteins by accelerating GTP hydrolysis on the Gα subunits. Palmitoylation, the reversible addition of palmitate to cysteine residues, occurs on several RGS proteins and is critical for their activity. For RGS16, mutation of Cys-2 and Cys-12 blocks its incorporation of E^3Hlpalmitate and ability to turn-off G_i and G_q signaling and significantly inhibited its GTPase activating protein activity toward a Gα subunit fused to the 5-hydroxytryptamine receptor 1A, but did not reduce its plasma membrane localization based on cell fractionation studies and immunoelectron microscopy. Palmitoylation can target proteins, including many signaling proteins, to membrane microdomains, called lipid rafts. A subpopulation of endogenous RGS16 in rat liver membranes and overexpressed RGS16 in COS cells, but not the non-palmitoylated cysteine mutant of RGS16, localized to lipid rafts. However, disruption of lipid rafts by treatment with methyl-j3-cyclodextrin did not decrease the GTPase activating protein activity of RGS16. The lipid raft fractions were enriched in protein acyltransferase activity, and RGS16 incorporated E^3Hlpalmitate into a peptide fragment containing Cys-98, a highly conserved cysteine within the RGS box. These results suggest that the amino-terminal palmitoylation of an RGS protein promotes its lipid raft targeting that allows palmitoylation of a poorly accessible cysteine residue that we show in the accompanying article (Osterhout, J. L., Waheed, A. A., Hiol, A., Ward, R. J., Davey, P. C., Nini, L., Wang, J., Milligan, G., Jones, T. L. Z., and Druey, K. M. (2003) *J. BioL Chem.* 278,19309-19316) was critical for RGS16 and RGS4 GAP activity.

3.385 Palmitoylation regulates regulators of G-protein signaling (RGS) 16 function: II Palmitoylation of a cysteine residue in the RGS box is critical for RGS16 GTPase accelerating activity and regulation of G_i-coupled signaling

Osterhout, J.L. et al.

J. Biol. Chem., ***278***, *19309-19316 (2003)*

Palmitoylation is a reversible post-translational modification used by cells to regulate protein activity. The regulator of G-protein signaling (RGS) proteins RGS4 and RGS16 share conserved cysteine (Cys) residues that undergo palmitoylation. In the accompanying article (Hiol, A., Davey, P. C., Osterhout, J. L., Waheed, A. A., Fischer, E. H., Chen, C. K., Milligan, G., Druey, K. M., and Jones, T. L. Z. (2003) *J. BioL Chem.* 278, 19301-19308), we determined that mutation of NH_2-terminal cysteine residues in RGS16 (Cys-2 and Cys-12) reduced GTPase accelerating (GAP) activity toward a 5-hydroxytryptamine ($5\text{-}HT_{1A}$)/$G\alpha_{o1}$ receptor fusion protein in cell membranes. NH_2-terminal acylation also permitted palmitoylation of a cysteine residue in the RGS box of RGS16 (Cys-98). Here we investigated the role of internal palmitoylation in RGS16 localization and GAP activity. Mutation of RGS16 Cys.98 or RGS4 Cys-95 to alanine reduced GAP activity on the $5\text{-}HT_{1A}$/$G\alpha_{o1}$ fusion protein and regulation of adenylyl cyclase inhibition. The C98A mutation had no effect on RGS16 localization or GAP activity toward purified G-protein a subunits. Enzymatic palmitoylation of RGS16 resulted in internal palmitoylation on residue Cys-98. Palmitoylated RGS16 or RGS4 WT but not C98A or C95A preincubated with membranes expressing $5\text{-}HT_{1A}$/$G\alpha_{o1}$ displayed increased GAP activity over time. These results suggest that palmitoylation of a Cys residue in the RGS box is critical for RGS16 and RGS4 GAP activity and their ability to regulate G_i-coupled signaling in mammalian cells.

3.386 Differential mobilization of newly synthesized cholesterol and biosynthetic sterol precursors from cells

Lusa, S., Heino, S. and Ikonen, E.
J. Biol. Chem., ***278***, *19844-19851 (2003)*

Previous work demonstrates that the biosynthetic precursor of cholesterol, desmosterol, is released from cells and that its efflux to high density lipoprotein or phosphatidylcholine vesicles is greater than that of newly synthesized cholesterol (Johnson, W. J., Fischer, H. T., Phillips, M. C., and Rothblat, G. H. (1995) *J. BioL Chem.* 270, 25037-25046). Here we report that the release of individual precursor sterols varies with the efflux of newly synthesized zymosterol being greater than that of lathosterol and both exceeding that of newly synthesized cholesterol when using either methyl-β-cyclodex-trin or complete serum as acceptors. The transfer of newly synthesized lathosterol to methyl-β-cyclodextrin was inhibited by actin polymerization but not by Golgi disassembly whereas that of newly synthesized cholesterol was inhibited by both conditions. Newly synthesized lathosterol associated with cellular detergent-resistant membranes more rapidly than newly synthesized cholesterol. Upon efflux to serum, newly synthesized cholesterol precursors associated with both high and low density lipoproteins. Stimulation of the formation of direct endoplasmic reticulum-plasma membrane contacts was accompanied by enhanced efflux of newly synthesized lathosterol but not of newly synthesized cholesterol to serum acceptors. The data indicate that the efflux of cholesterol precursors differs not only from that of cholesterol but also from each other, with the more polar zymosterol being more avidly effluxed. Moreover, the results suggest that the intracellular routing of cholesterol precursors differs from that of newly synthesized cholesterol and implicates a potential role for the actin cytoskeleton and endoplasmic reticulum-plasma membrane contacts in the efflux of lathosterol.

3.387 Presenilin 1 and Presenilin 2 have differential effects on the stability and maturation of Nicastrin in mammalian brain

Chen, F. et al.
J. Biol. Chem., ***278***, *19974-19979 (2003)*

The presenilins and nicastrin form high molecular mass, multimeric protein complexes involved in the in. tramembranous proteolysis of several proteins. Post-translational glycosylation and trafficking of nicastrin is necessary for the activity of these complexes. We report here that although there are differences in the post-translational processing of nicastrin in neurons and glia, both of the presenilins are required for the physiological post-translational modification and for the correct subcellular distribution of nicastrin. Absence of presenilin 1 (PS1) is associated with dramatic reductions in the level of mature glycosylated nicastrin and with redistribution of nicastrin away from the cell surface. In contrast, absence of presenilin 2 (PS2) is associated with only modest reductions in the levels of immature nicastrin. It is notable that these differential effects parallel the differential effects of null mutations in PS1 and PS2 on APP and Notch processing. Our data there. fore suggest that the differential interactions of PS1 and PS2 with nicastrin reflect different functions for the PS1 and PS2 complexes.

3.388 Synergistic assembly of linker for activation of T cells signaling protein complexes in T cell plasma membrane domains

Hartgrove, L., Lin, J., Langen, H., Zech, T., Weiss, A. and Harder, T.
J. Biol. Chem., ***278***, *20389-20394 (2003)*

Transmembrane adaptor molecule LAT (linker for activation of T cells) forms a central scaffold for signaling protein complexes that accumulate in the vicinity of activated T cell antigen receptors (TCR). Here we used biochemical analysis of immunoisolated plasma membrane domains and fluorescence imaging of green fluorescence protein-tagged signaling proteins to investigate the contributions of different tyrosine.based signaling protein docking sites of LAT to the formation of LAT signaling protein assemblies in TCR membrane domains. We found that the phospholipase C γ docking site of LAT and different Grb2/Gads docking sites function in an interdependent fashion and synergize to accumulate LAT, Grb2, and phospholipase C γ in TCR signaling assemblies. Two-dimensional gels showed that Grb2 is a predominant cytoplasmic adaptor in the isolated LAT signaling complexes, whereas Gads, Crk-1, and Grap are present in lower amounts. Taken together our data suggest a synergistic assembly of multimolecular TCR-LAT signal transduction complexes in T cell plasma membrane domains.

3.389 A novel method of imaging lysosomes in living human mammary epithelial cells

Glunde, K., Guggino, S.E., Ichikawa, Y. and Bhujwalla, Z.M.
Mol. Imaging, ***2***, *24-36 (2003)*

Cancer cells Invade by secreting degradative enzymes which, under normal conditions, are sequestered in lysosomal vesicles. The ability to non-invasively label lysosomes and track lysosomal trafficking would be extremely useful to understand the mechanisms by which degradative enzymes are secreted in the presence of pathophysiological environments, such as hypoxia and acidic extracellular pH, which are frequently encountered in solid tumors. In this study, a novel method of introducing a fluorescent label into lysosomes of human mammary epithellal cells (HMECs) was evaluated. Highly glycosylated lysosomal membrane proteins were labeled with a newly synthesized compound, 5-dimethylamino-naphthalene-1-sulfonic acid 5-amino-3,4,6-trihydroxy-tetrahydro-pyran-2-ylmethyl ester (6-O-dansyl.G1cNH_2). The ability to optically image lysosomes using this new probe was validated by determining the colocalization of the fluorescence from the dansyl group with immunofluorescent staining of two well-established lysosomal marker proteins, LAMP-1 and LAMP-2. The location of the dansyl group in lysosomes was also verified by using an anti-dansyl antibody in Western blots of lysosomes isolated using isopycnic density gradient centrifugation. This novel method of labeling lysosomes biosynthetically was used to image lysosomes in living HMECs perfused In a microscopy-compatible cell perfusion system.

3.390 Fyn binds to and phosphorylates the kidney slit diaphragm component Nephrin

Verma, R. et al.
J. Biol. Chem., ***278***, *20716-20723 (2003)*

Recent investigations have focused on characterizing the molecular components of the podocyte intercellular junction, because several of these components, including Nephrin, are functionally necessary for develop. ment of normal podocyte structure and filter integrity. Accumulating evidence suggests that the Nephrin-asso. ciated protein complex is a signaling nexus. As such, Nephrin-dependent signaling might be mediated in part through Nephrin phosphorylation. Described are biochemical and mouse genetics experiments demonstrating that membrane-associated Nephrin is tyrosine-phosphorylated by the Src family kinase Fyn. Nephrin fractionated in detergent-resistant glomerular membrane fractions with Fyn and Yes. Fyn directly bound Nephrin via its SH3 domain, and Fyn directly phosphorylated Nephrin. Glomeruli in which Fyn, Yes, or Fyn and Yes were genetically deleted in mice were charac. terized to explore the relationship between these kinases and Nephrin. Fyn deletion resulted in coarsening of podocyte foot processes and marked attenuation of Nephrin phosphorylation in isolated glomerular deter-gent-resistant membrane fractions. Yes deletion had no identifiable effect on podocyte morphology but dramatically increased Nephrin phosphorylating activity. Similar to Fyn deletion, simultaneous deletion of Fyn and Yes reduced Nephrin phosphorylating activity. These results demonstrate that endogenous Fyn catalyzes Nephrin phosphorylation in podocyte detergent-resistant membrane fractions. Although Yes appears to effect the regulation of Nephrin phosphorylation, the mechanism by which this occurs requires investigation.

3.391 Ultracentrifugation-based approaches to study regulation of Sec6/8 (exocyst) complex function during development of epithelial cell polarity
Yeaman, C.
*Methods **30**, 198-206 (2003)*

The Sec6/8 (exocyst) complex is an essential component of the exocytic apparatus and plays an evolutionarily conserved role in polarized membrane growth. During development of epithelial cell polarity, this cytosolic protein complex is recruited to plasma membrane sites of cell-cell contact, where it facilitates exocytosis to the lateral membrane domain. However, the identity of membrane binding sites for Sec6/8 complex, mechanisms regulating association of Sec6/8 complex with these sites, and the precise function of the complex in polarized trafficking are not known. Biochemical strategies involving differential, rate-zonal, and isopycnic density gradient ultracentrifugation are providing clues to these questions.

3.392 Disruption of the epithelial apical-junction complex by *Helicobacter pylori* CagA
Amieva, M.R., Vogelmann, R., Covacci, A., Tompkins, L.S., Nelson, W.J. and Falkow, S.
*Science, **300**, 1430-1434 (2003)*

Helicobacter pylori translocates the protein CagA into gastric epithelial cells and has been linked to peptic ulcer disease and gastric carcinoma. We show that injected CagA associates with the epithelial tight-junction scaffolding protein ZO-1 and the transmembrane protein junctional adhesion molecule, causing an ectopic assembly of tight-junction components at sites of bacterial attachment, and altering the composition and function of the apical-junctional complex. Long-term CagA delivery to polarized epithelia caused a disruption of the epithelial barrier function and dysplastic alterations in epithelial cell morphology. CagA appears to target *H. pylori* to host cell intercellular junctions and to disrupt junction-mediated functions.

3.393 Expression of the molecular chaperone Hsp70 in detergent-resistant microdomains correlates with its membrane delivery and release
Broquet, A.H., Thomas, G., Masliah, J., Trugnan, G. and Bachelet, M.
*J. Biol. Chem., **278**, 21601-21606 (2003)*

Accumulating evidence suggests that some heat shock proteins (Hsps), in particular the 72-kDa inducible Hsp70, associate to the cell membrane and might be secreted through an unknown mechanism to exert important functions in the immune response and signal transduction. We speculated that specialized structures named lipid rafts, known as important platforms for the delivery of proteins to the cell membrane, might be involved in the unknown mechanism ensuring membrane association and secretion of Hsp70. Lipid rafts are sphingolipid-cholesterol-rich structures that have been mainly characterized in polarized epithelial cells and can be isolated as detergent-resistant microdomains (DRMs). Analysis of soluble and DRM fractions prepared from unstressed Caco-2 epithelial cells revealed that Hsp70, and to a lesser extent calnexin, were present in DRM fractions. Increased expression of Hsps, through heat shock or by using drugs acting on protein trafficking or intracellular calcium level, induced an efficient translocation to DRM. We also found that Hsp70 was released by epithelial Caco-2 cells, and this release dramatically increased after heat shock. Drugs known to block the classical secretory pathway were unable to reduce Hsp70 release. By contrast, release of the protein was affected by the raft-disrupting drug methyl-β-cyclodextrin. Our data suggest that lipid rafts are part of a mechanism ensuring the correct functions of Hsps and provide a rational explanation for the observed membrane association and release of Hsp70.

3.394 Organization of the G protein-coupled receptors rhodopsion and opsin in native membranes
Liang, Y., Fotiadis, D., Filipek, S., Saperstein, D.A., Palczewski, K. and Engel, A.
J. Biol. Chem., ***278***, *21655-21662 (2003)*

G protein-coupled receptors (GPCRs), which constitute the largest and structurally best conserved family of signaling molecules, are involved in virtually all physiological processes. Crystal structures are available only for the detergent-solubilized light receptor rhodopsin. In addition, this receptor is the only GPCR for which the presumed higher order oligomeric state in native membranes has been demonstrated (Fotiadis, D., Liang, Y., Filipek, S., Saperstein, D. A., Engel, A., and Palczewski, K (2003) *Nature* 421, 127-128). Here, we have determined by atomic force microscopy the organization of rhodopsin in native membranes obtained from wild-type mouse photoreceptors and opsin isolated from photoreceptors of *Rpe65-/-* mutant mice, which do not produce the chromophore 11-*cis*-retinal. The higher order organization of rhodopsin was present irrespective of the support on which the membranes were adsorbed for imaging. Rhodopsin and opsin form structural dimers that are organized in paracrystalline arrays. The intradimeric contact is likely to involve helices IV and V, whereas contacts mainly between helices I and II and the cytoplasmic loop connecting helices V and VI facilitate the formation of rhodopsin dimer rows. Contacts between rows are on the extracellular side and involve helix I. This is the first semi-empirical model of a higher order structure of a GPCR in native membranes, and it has profound implications for the understanding of how this receptor interacts with partner proteins.

3.395 Novel localization of the DNA-PK complex in lipid rafts: a putative role in the signal transduction pathway of the ionizing radiation response
Lucero, H., Gae, D. and Taccioli, G.E.
J. Biol. Chem., ***278***, *22136-22143 (2003)*

Increased sensitivity to ionizing radiation (IR) has been shown to be due to defects in DNA double-strand break repair machinery. The major pathway in mammalian cells dedicated to the repair of DNA double-strand breaks is by the nonhomologous end-joining machinery. Six components function in this pathway, of which three (Ku70, Ku86, and DNA-PKcs) constitute a protein complex known as DNA-dependent protein kinase (DNAPK). However, it is now recognized that the cellular radiation response is complex, and radiosensitivity may be also regulated at different levels in the radiation signal transduction pathway. In addition to DNA damage, exposure to IR triggers intracellular signaling cascades that overlap with pathways initiated by ligand engagement to a receptor. In this study, we provide evidence for the novel localization of the DNA-PK complex in lipid rafts. We also show this property is not a generalized characteristic of all DNA repair proteins. Furthermore, we have detected Ku86 in yeast lipid rafts. Our results suggest that the components of this complex might be recruited separately to the plasma membrane by tethering with raft-resident proteins. In addition, we found an irradiation-induced differential protein phosphorylation pattern dependent upon DNA-PKcs in lipid rafts. Thus, we speculate that another role for the DNAPKcs subunit and perhaps for the holoenzyme is in the signal transduction of IR response.

3.396 Virus entry, assembly, budding and membrane rafts (Review article)
Chazal, N. and Gerlier, D.
Microbiol. Mol. Biol. Rev., ***67***, *226-237 (2003)*

Specific microdomains of the plasma membrane called rafts appear to be involved in many biological events such as biosynthetic traffic, endocytic traffic, and the signal transduction pathway. Among pathogens, viruses, which are obligate intracellular parasites, are confronted with the plasma membrane during their life cycle. They have to enter their host cells by fusion, permeation, or endocytic vesicle discharge and to exit them by budding or membrane disruption.
In this review, we focus on data supporting the involvement of membrane rafts in the virus replication cycle, their role as a viral entry site, a platform for the assembly of viral components, and a scaffold for the budding of virus from infected cells. The elucidation of these interactions requires a detailed understanding of raft structures and dynamics.

3.397 GAP43 stimulates inositol trisphosphate-mediated calcium release in response to hypotonicity
Caprini, M. et al.
*The EMBO J., **22**, 3004-3014 (2003)*

The identification of osmo/mechanosensory proteins in mammalian sensory neurons is still elusive. We have used an expression cloning approach to screen a human dorsal root ganglion cDNA library to look for proteins that respond to hypotonicity by raising the intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$). We report the unexpected identification of GAP43 (also known as neuromodulin or B50), a membrane-anchored neuronal protein implicated in axonal growth and synaptic plasticity, as an osmosensory protein that augments $[Ca^{2+}]_i$, in response to hypoton-icity. Palmitoylation of GAP43 plays an important role in the protein osmosensitivity. Depletion of intracellular stores or inhibition of phospholipase C (PLC) activity abrogates hypotonicity-evoked, GAP43-mediated $[Ca^{2+}]_i$ elevations. Notably, hypotonicity promoted the selective association of GAP43 with the PLC-δ_1 isoform, and a concomitant Increase in inositol-1,4,5-trisphospbate (IP_3) formation. Collectively, these findings Indicate that hypo-osmotic activation of GAP43 induces Ca^{2+} release from IP_3-sensitive intracellular stores. The osmosensitivity of GAP43 furnishes a mechanistic framework that links axon elongation with phosphoinositide metabolism, spontaneous triggering of cytosolic Ca^{2+} transients and the regulation of actin dynamics and motility at the growth cone in response to temporal and local mechanical forces.

3.398 Presenilin endoproteolysis mediated by an aspartyl protease activity pharmacologically distinct from γ-secretase
Campbell, W.A., Reed, M.L.O., Strahle, J., Wolfe, M.S. and Xia, W.
*J. Neurochem., **85**, 1563-1574 (2003)*

Presenilin (PS)-dependent γ-secretase cleavage is the final proteolytic step in generating amyloid β protein (Aβ), a key peptide involved in the pathogenesis of Alzheimer's disease. PS undergoes endoproteolysis by an unidentified 'presenilinase' to generate the functional N-terminal and C-terminal fragment heterodimers (NTF/CTF) that may harbor the γ-secretase active site. To better understand the relationship between presenilinase and γ-secretase, we characterized the biochemical properties of presenilinase and compared them with those of γ-secretase. Similar to γ-secretase, presenilinase was most active at acidic pH 6.3. Aspartyl protease inhibitor pepstatin A blocked presenilinase activity with an IC_{50} of ~1 μM. Difluoroketone aspartyl protease transition state analogue MW167 was relatively selective for presenilinase (IC_{50} < 1μM) over γ-secretase (IC_{50} - 16 μM). Importantly, removing the transition state mimicking moiety simultaneously abolished both presenilinase and γ-secretase inhibition, suggesting that presenilinase, like γ-secretase, is an aspartyl protease. Interestingly, several of the most potent γ-secretase inhibitors (IC_{50} = 0.3 or 20 μM) failed to block presenilinase activity. Although *de novo* generation of PS1 fragments coincided with production of Aβ *in vitro*, blocking presenilinase activity without reducing pre-existing fragment levels permitted normal *do novo* generation of Aβ and amyloid intracellular domain. Therefore, presenilinase has characteristics of an aspartyl protease, but this activity is distinct from γ-secretase.

3.399 NGF signaling in sensory neurons: evidence that early endosomes carry NGF retrograde signals
Delcroix, J-D., Valletta, J.S., Wu, C., Hunt, S.J., Kowal, A.S. and Mobley, W.C.
*Neuron, **39**¸69-84 (2003)*

Target-derived NGF promotes the phenotypic maintenance of mature dorsal root ganglion (DRG) nociceptive neurons. Here, we provide in vivo and in vitro evidence for the presence within DRG neurons of endosomes containing NGF, activated TrkA, and signaling proteins of the Rapl/Erkl/2, p38MAPK, and PI3K/Akt pathways. Signaling endosomes were shown to be retrogradely transported in the isolated sciatic nerve in vitro. NGF injection in the peripheral target of DRG neurons increased the retrograde transport of p-Erkl/2, p-p38, and pAkt in these membranes. Conversely, NGF antibody injections decreased the retrograde transport of p-Erkl/2 and p-p38. Our results are evidence that signaling endosomes, with the characteristics of early endosomes, convey NGF signals from the target of nociceptive neurons to their cell bodies.

3.400 Cell surface expression of functional hepatitis C virus E1 and E2 glycoproteins
Drummer, H.E., Maerz, A. and Poumbourios, P.
*FEBS Lett., **546**, 385-390 (2003)*

Hepatitis C virus (HCV) glycoproteins El and E2 are believed to be retained in the endoplasmic reticulum (ER) or *cis*-Golgi compartment via retention signals located in their transmembrane domains. Here we describe the detection of El and E2 at the surface of transiently transfected HEK 293T and Huh7 cells. Surface-localized E1E2 heterodimers presented exclusively as non-covalently associated complexes. Surface-expressed E2 contained *trans*-Golgi modified complex/hybrid type carbohydrate and migrated diffusely between 70 and 90 kDa while intracellular El and E2 existed as high mannose 35 kDa and 70 kDa precursors, respectively. In addition, surface-localized E1E2 heterodimers were incorporated into E1E2-pseudotyped HIV-l particles that were competent for entry into Huh7 cells. These studies suggest that functional HCV glycoproteins are not retained exclusively in the ER and transit through the secretory pathway.

3.401 Distinct endosomal compartments in early trafficking of low density lipoprotein-derived cholesterol
Sugii, S., Reid, P.C., Ohgami, N., Du, H. and Chang, T-Y.
*J. Biol. Chem., **278**, 27180-27189 (2003)*

We previously studied the early trafficking of low density lipoprotein (LDL)-derived cholesterol in mutant Chinese hamster ovary cells defective in Niemann-Pick type Cl (NPC1) using cyclodextrin (CD) to monitor the arrival of cholesterol from the cell interior to the plasma membrane (PM) (Cruz, J. C., Sugii, S., Yu, C., and Chang, T.-Y. *(2000) J. BioL Chem.* 215,4013-4021). We found that newly hydrolyzed cholesterol derived from LDL first appears in certain CD-accessible pool(s), which we assumed to be the PM, before accumulating in the late endosome/lysosome, where NPC1 resides. To determine the identity of the early CD-accessible pool(s), in this study, we performed additional experiments, including the use of revised CD incubation protocols. We found that prolonged incubation with CD (>30 min) caused cholesterol in internal membrane compartment(s) to redistribute to the PM, where it became accessible to CD. In contrast, a short incubation with CD (5-10 min) did not cause such an effect. We also show that one of the early compartments contains acid lipase (AL), the enzyme required for liberating cholesterol from cholesteryl ester in LDL Biochemical and microscopic evidence indicates that most of the AL is present in endocytic compartment(s) distinct from the late endosome/lysosome. Our results suggest that cholesterol is liberated from LDL cholesteryl ester in the hydrolytic compartment containing AL and then moves to the NPC1-containing late endosome/lysosome before reaching the PM or the endoplasmic reticulum.

3.402 Syntaxin 6 regulates Glut4 trafficking in 3T3-L1 adipocytes
Perera, H.K.I., Clarke, M., Morris, N.J., Hong, W., Chamberlain, L.H. and Gould, G.W.
*Mol. Biol. Cell, **14**, 2946-2958 (2003)*

Insulin stimulates the movement of glucose transporter-4 (Glut4)-containing vesicles to the plasma membrane of adipose cells. We investigated the role of post-Golgi t-soluble *N*-ethylmaleimide-sensitive factor attachment protein receptors (SNAREs) in the trafficking of Glut4 in 3T3-L1 adipocytes. Greater than 85% of syntaxin 6 was found in Glut4-containing vesides, and this t-SNARE exhibited insulin-stimulated movement to the plasma membrane. In contrast, the colocalization of Glut4 with syntaxin 7, 8, or 12/13 was limited and these molecules did not translocate to the plasma membrane. We used adenovirus to overexpress the cytosolic domain of these syntaxins and studied their effects on GIut4 traffic. Overexpression of the cytosolic domain of syntaxin 6 did not affect insulin-stimulated glucose transport, but increased basal deGlc transport and cell surface Glut4 levels. Moreover, the syntaxin 6 cytosolic domain significantly reduced the rate of Glut4 re-internalization after insulin withdrawal and perturbed sub-endosomal Glut4 sorting; the corresponding domains of syntaxins 8 and 12 were without effect. Our data suggest that syntaxin 6 is involved in a membrane-trafficking step that sequesters Glut4 away from traffic destined for the plasma membrane. We speculate that this is at the level of traffic of Glut4 into its unique storage compartment and that syntaxin 16 may be involved.

3.403 Bursts of high-frequency stimulation trigger rapid delivery of pre-existing α-CaMKII mRNA to synapses: a mechanism in dendritic protein synthesis during long-term potentiation in adult awake rats

Havik, B., Rokke, H., Bardsen, K., Davanger, S. and Bramham, C.R.
Eur. J. Neurosci., ***17****, 2679-2689 (2003)*

Messenger ribonucleic acid encoding the alpha-subunit of calcium/calmodulin-dependent protein kinase II *(camkII)* is abundantly and constitutively expressed in dendrites of pyramidal and granule cell neurons of the adult hippocampus. Recent evidence suggests that *camkII* messenger ribonucleic acid is stored in a translationally dormant state within ribonucleic acid storage granules. Delivery of *camkII* messenger ribonucleic acid from sites of storage to sites of translation may therefore be a key step in activity-driven dendritic protein synthesis and synaptic plasticity. Here we explored possible *camkII* trafficking in the context of long-term potentiation in the dentate gyrus of awake, adult rats. Long-term potentiation was induced by patterned high-frequency stimulation, synaptodendrosomes containing pinched-off dendritic spines were obtained from microdissected dentate gyrus, and messenger ribonucleic acid levels were determined by real-time polymerase chain reaction. High-frequency stimulation triggered a rapid 2.5-fold increase in *camkII* messenger ribonucleic acid levels in the synaptodendrosome fraction. This increase occurred in the absence of *camkII* upregulation in the homogenate fraction, indicating trafficking of pre-existing messenger ribonucleic acid to synaptodendrosomes. The elevation in *camkII* messenger ribonucleic acid was paralleled by an increase in protein expression specific to the synaptodendrosome fraction, and followed by depletion of *camkII* message. Activity-dependent regulation of *camkII* messenger ribonucleic acid and protein did not require N-methyl-D-aspartate receptor activation. In contrast, *N*-methyl-D-aspartate receptor activation was required for induction of the immediate early genes *zif268* and *activity-regulated cytoskeleton-associated protein* in dentate gyrus homogenates. The results support a model in which locally stored *camII* messenger ribonucleic acid is rapidly transported to dendritic spines and translated during long-term potentiation in behaving rats.

3.404 Ergosterol is required for targeting of tryptophan permease to the yeast plasma membrane

Umebayashi, K. and Nakano, A.
J. Cell Biol., ***161****, 1117-1131 (2003)*

It was known that the uptake of tryptophan is reduced in the yeast *erg6* mutant, which is defective in a late step of ergosterol biosynthesis. Here, we show that this is because the high affinity tryptophan permease Tat2p is not targeted to the plasma membrane. In wild-type cells, the plasma membrane localization of Tat2p is regulated by the external tryptophan concentration. Tat2p is transported from the Golgi apparatus to the vacuole at high tryptophan, and to the plasma membrane at low tryptophan. However, in the *erg6* mutant, Tat2p is missorted to the vacuole at low tryptophan. The plasma membrane targeting of Tat2p is dependent on detergent-insoluble membrane domains, suggesting that sterol affects the sorting through the organization of lipid rafts. The *erg6* mutation also caused missorting to the multivesicular body pathway in late endosomes. Thus, sterol composition is crucial for protein sorting late in the secretory pathway. Tat2p is subject to polyubiquitination, which acts as a vacuolar-targeting signal, and the inhibition of this process suppresses the Tat2p sorting defects of the *erg6* mutant. The sorting mechanisms of Tat2p that depend on both sterol and ubiquitin will be discussed.

3.405 Pharmacological characterization and immunoaffinity purification of metabotropic glutamate receptor from *Drosophila* overexpressed in Sf9 cells

Panneels, V., Eroglu, C., Cronet, P. and Sinning, I.
Prot. Expression Purification, ***20****, 275-282 (2003)*

Metabotropic glutamate receptors (mGluRs) play important roles in the function and regulation of the central nervous system. Structural studies are necessary for the detailed understanding of their mechanisms of action. However, overexpression and purification of functional receptors in quantities required for these studies proves to be a major challenge. In this study we report the overexpression of a *Drosophila melanogaster* mGluR (DmG1uRA) by using a baculovirus—insect cell expression system. Expression was tested in two different insect cell hosts (Sf9 and Hi5) and analyzed by performing expression kinetics. Pharmacological characterization of the recombinant receptor by radioactive glutamate binding assays showed a profile similar to group II mGluRs, as previously reported, when the receptor was expressed in mammalian systems. The B_{max} value reached 11 pmol receptor/mg Sf9-membrane protein. A monoclonal antibody against DmG1uRA was generated by genetic immunization and used to purify the receptor.

3.406 Inhibition of GTP-dependent vesicle trafficking impairs internalization of palsmalemmal eNOS and cellular nitric oxide production

Chaterjee, S., Cao, S., Peterson, T.E., Simari, R.D. and Shah, V.

J. Cell Sci., ***116****, 3645-3655 (2003)*

The Ca^{2+} mobilizing peptide, bradykinin (BK), stimulates endothelial nitric oxide synthase (eNOS)-derived cellular nitric oxide (NO) production in association with altering the subcellular distribution of the enzyme. In the present study we examine the influence of cellular GTPases, particularly the large GTPase dynamin, on BK-mediated eNOS localization and cellular NO production. BK stimulation of ECV cells, which were stably transfected with eNOS-GFP (eNOS-GFP ECV304), increased NO production. This was associated with the mobilization of eNOS-GFP protein into Triton X-100-insoluble fractions of cell lysates, and an internalization of plasmalemmal eNOS-GFP in live and fixed ECV 304 cells. Incubation of digitonin-permeabilized ECV304 cells with the non-hydrolyzed GTP analog, GTPγ-S, abrogated the BK-mediated internalization of eNOS-GFP as assessed by confocal microscopy. Conversely, inhibition of clathrin--dependent endocytosis, via overexpression of AP 180 or pretreatment of cells with chlorpromazine, did not influence BK-mediated eNOS redistribution. Furthermore, specific inhibition of dynamin-2 GTPase function by overexpression of a dominant negative construct, K44A, prevented the BK-mediated enrichment of eNOS-GFP within low buoyant density, caveolin-enriched fractions of eNOS-GFP ECV304 cell lysates. Dynamin-2 K44A overexpression also markedly impaired BK-dependent, L-NAME-inhibited NO production as did incubation of permeabilized cells with GTP-γ-s. These studies demonstrate that disruption of dynamin- and GTPdependent, but clathrin-independent, vesicle trafficking pathways impairs BK-dependent cellular NO production, via inhibition of the internalization of eNOS-containing plasmalemmal vesicles.

3.407 Identification of organelles in bacteria similar to acidocalsisomes of unicellular eukaryotes

Seufferheld, M. et al

J. Biol. Chem., ***278(32)****, 29971-29978 (2003)*

Acidocalcisomes are acidic calcium storage compartments described in several unicellular eukaryotes, including trypanosomatid and apicomplexan parasites, algae, and slime molds. In this work, we report that the volutin granules of *Agrobacterium tumefaciens* possess properties similar to the acidocalcisomes. Transmission electron microscopy revealed that each intracellular granule was surrounded by a membrane. X-ray microanalysis of the volutin granules showed large amounts of phosphorus, magnesium, potassium, and calcium. Calcium in the volutin granules increased when the bacteria were incubated at high extracellular calcium concentration. Immunofluorescence and immunoelectron microscopy, using antisera raised against peptide sequences conserved in the *A. tumefaciens* proton pyrophosphatase, indicated localization in intracellular vacuoles. Purification of the volutin granules using **iodixanol** density gradients indicated a preferential localization of the pyrophosphatase activity in addition to high concentrations of phosphate, pyrophosphate, short- and long-chain polyphosphate, but lack of markers of the plasma membrane. The pyrophosphatase activity was potassium-insensitive and inhibited by the pyrophosphate analogs, amynomethylenediphosphonate and imidodiphosphate, by dicyclohexylcarbodiimide, and by the thiol reagent *N*-ethylmaleimide. Polyphosphate was also localized to the volutin granules by 4',6'-diamino-2-phenylindole staining. The organelles were acidic, as demonstrated by staining with LysoSensor blue DND-167, a dye especially used to detect very acidic compartments in cells, and cycloprodigiosin, a compound isolated from a marine bacterium that has been shown to uncouple proton pyrophosphatase activity acting as a chloride/proton symport. The results suggest that acidocalcisomes arose before the prokaryotic and eukaryotic lineages diverged.

3.408 Association of the Golgi UDP-galactose transporter with UDP-galactose: ceramide galactosyltransferase allows UDP-galactose import in the endoplasmic reticulum

Sprong, H. et al

Mol. Biol. Cell, ***14****, 3482-3493 (2003)*

UDP-galactose reaches the Golgi lumen through the UDP-galactose transporter (UGT) and is used for the galactosylation of proteins and lipids. Ceramides and diglycerides are galactosylated within the endoplasmic reticulum by the UDP-galactose:ceramide galactosyltransferase. It is not known how UDP-galactose is transported from the cytosol into the endoplasmic reticulum. We transfected ceramide galactosyltransferase cDNA into CHOlec8 cells, which have a defective UGT and no endogenous ceramide galactosyltransferase. Cotransfection with the human UGT1 greatly stimulated synthesis of lactosylceramide in the Golgi and of galactosylceramide in the endoplasmic reticulum. UDP-galactose was

directly imported into the endoplasmic reticulum because transfection with UGT significantly enhanced synthesis of galactosylceramide in endoplasmic reticulum membranes. Subcellular fractionation and double label immunofluorescence microscopy showed that a sizeable fraction of ectopically expressed UGT and ceramide galactosyltransferase resided in the endoplasmic reticulum of CHOlec8 cells. The same was observed when UGT was expressed in human intestinal cells that have an endogenous ceramide galactosyltransferase. In contrast, in CHOlec8 singly transfected with UGT 1, the transporter localized exclusively to the Golgi complex. UGT and ceramide galactosyltransferase were entirely detergent soluble and form a complex because they could be coimmunoprecipitated. We conclude that the ceramide galactosyltransferase ensures a supply of UDP-galactose in the endoplasmic reticulum lumen by retaining UGT in a molecular complex.

3.409 Screening for nitric oxide-dependent protein-protein interactions
Matsumoto, A., Comatas, K.E., Liu, L. and Stamler, J.S.
Science, ***301***, *657-661 (2003)*

Because nitric oxide (NO) may be a ubiquitous regulator of cellular signaling, we have modified the yeast two-hybrid system to explore the possibility of NO-dependent protein-protein interactions.We screened for binding partners of procaspase-3, a protein implicated in apoptotic signaling pathways, and identified multiple NO-dependent interactions.Two such interactions, with acid sphingomyelinase and NO synthase, were shown to occur in mammalian cells dependent on endogenous NO.Nitrosylation may thus provide a broad-based mechanism for regulating interactions between proteins.If so, systematic proteomic analyses in which redox state and NO bioavailability are carefully controlled will reveal a large array of novel interactions.

3.410 The yeast deubiquitinating enzyme Ubp16 is anchored to the outer mitochondrial membrane
Kinner, A. and Kölling, R.
FEBS Lett., ***549***, *135-140 (2003)*

We looked for membrane-associated Dubs (deubiquitinating enzymes) among the 16 yeast members of the ubiquitin-specific processing protease (Ubp) family to identify potential regulators of ubiquitin-dependent processes at membranes. For each of the Ubps examined, a certain fraction was found to be membrane associated. This fraction was only small for most Ubps but quite substantial for some Ubps. For Ubp4/Doa4 almost 40% of the protein was found in the membrane fraction suggesting that this protein performs a major function at membranes, probably at endosomes. Among the proteins tested, only one protein (Ubp16) was exclusively membrane associated. By cell fractionation and immunofluorescence experiments, we could show that Ubp16 is localized to mitochondria. Ubp16 contains an N-terminal hydrophobic domain that is similar to N-terminal sequences of other yeast outer mitochondrial membrane proteins. The presence of this putative signal sequence and the result of protease protection experiments suggest that Ubp16 is an integral membrane protein of the outer mitochondrial membrane with an N_{in}–C_{out} orientation. Phenotypic characterization of the Δ*ubp16* mutant and overexpression studies further suggest that Ubp16 is probably not important for the general functioning of mitochondria, but that it rather performs a more specialized function at mitochondria.

3.411 Rotavirus infectious particles use lipid rafts during replication for transport to the cell surface in vitro and in vivo
Cuadras, M.A. and Greeberg, H.B.
Virology, ***313***, *308-321 (2003)*

The pathway by which rotavirus is released from the cell is poorly understood but recent work has shown that, prior to cell lysis, rotavirus is released almost exclusively from the apical surface of the infected cell. By virtue of their unique biochemical and physical properties, viruses have exploited lipid rafts for host cell entry and/or assembly. Here we characterized the association of rhesus rotavirus (RRV) with lipid rafts during the rotavirus replication cycle. We found that newly synthesized infectious virus associates with rafts in vitro and in vivo. RRV proteins cosegregated with rafts on density gradients. Viral infectivity and genomic dsRNA also cosegregated with the raft fractions. Confocal microscopic analysis of raft and RRV virion proteins demonstrated colocalization within the cell. In addition, cholesterol depletion interfered with the association of RRV particles with rafts and reduced the release of infectious particles from the cell. Furthermore, murine rotavirus associates with lipid rafts in intestinal epithelial cells during a natural infection in vivo. Our results confirm the association of rotavirus infectious particles with rafts during

replication in vitro and in vivo and strongly support the conclusion that this virus uses these microdomains for transport to the cell surface during replication.

3.412 Glutamate-binding affinity of *Drosophila* metabotropic glutamate receptor is modulated by association with lipid rafts
Eroglu, C., Brügger, B., Wieland, F. And Sinning, I.
*PNAS, **100(18)**, 10219-10224 (2003)*

Metabotropic glutamate receptors (mGluRs) are responsible for the effects of glutamate in slow synaptic transmission, and are implicated in the regulation of many processes in the CNS. Recently, we have reported the expression and purification of a mGluR from *Drosophila melanogaster* (DmGluRA), a homologue of mammalian group II mGluRs. We have shown that ligand binding to reconstituted DmGluRA requires the presence of ergosterol in the liposomes [Eroglu, C., Cronet, P., Panneels, V., Beaufils, P. & Sinning, I. (2002) *EMBO Rep.* 3, 491-496]. Here we demonstrate that the receptor exists in different affinity states for glutamate, depending on the membrane composition. The receptor is in a high-affinity state when associated with sterol-rich lipid microdomains (rafts), and in a low-affinity state out of rafts. Enrichment of the membranes with cholesterol shifts the receptor into the high-affinity state, and induces its association with rafts. The receptor was crosslinked to photocholesterol. Our data suggest that sterol-rich lipid rafts act as positive allosteric regulators of DmGluRA.

3.413 Mutational analysis of the cytoplasmic domain of β1,4-galactosyltransferase I: influence of phosphorylation on cell surface expression
Hathaway, H.J. et al
*J. Cell Sci., **116**, 4319-4330 (2003)*

β1,4-Galactosyltransferase I (GalT I) exists in two subcellular compartments where it performs two distinct functions. The majority of GalT I is localized in the Golgi complex where it participates in glycoprotein biosynthesis; however, a small portion of GalT I is expressed on the cell surface where it functions as a matrix receptor by binding terminal *N*-acetylglucosamine residues on extracellular glycoside ligands. The GalT I polypeptide occurs in two alternate forms that differ only in the length of their cytoplasmic domains. It is thought that the longer cytoplasmic domain is responsible for GalT I function as a cell surface receptor because of its ability to associate with the detergent-insoluble cytoskeleton. In this study, we demonstrate that the long GalT I cytoplasmic and transmembrane domains are capable of targeting a reporter protein to the plasma membrane, whereas the short cytoplasmic and transmembrane domains do not have this property. The surface-localized GalT I reporter protein partitions with the detergent-insoluble pool, a portion of which co-fractionates with caveolin-containing lipid rafts. Site-directed mutagenesis of the cytoplasmic domain identified a requirement for serine and threonine residues for cell surface expression and function. Replacing either the serine or threonine with aspartic acid reduces surface expression and function, whereas substitution with neutral alanine has no effect on surface expression or function. These results suggest that phosphorylation negatively regulates GalT I function as a surface receptor. Consistent with this, phosphorylation of the endogenous, full-length GalT I inhibits its stable expression on the cell surface. Thus, the 13 amino acid extension unique to the long GalT I isoform is required for GalT I expression on the cell surface, the function of which is regulated by phosphorylation.

3.414 Abnormal cholesterol processing in Alzheimer's disease patient's fibroblasts
Dufour, D., Zhao, W-Q., Ravindranath, L. and Alkon, D.L.
*Neurobiol. Lipids., **1(7)**, 34-44 (2003)*

Cholesterol has recently received attention as a potentially important factor in Alzheimer's disease etiology. Caveolin, which binds cholesterol, plays a prominent role in cellular cholesterol transport. Here, we found a higher level of cholesterol and caveolin in the caveolae-enriched fractions prepared from Alzheimer's disease patients' (AD) fibroblasts compared with age and sex matched controls (AC). Furthermore, the cross-linking activation of the prion protein, which is known to link to signal transduction of caveolin, is altered in AD fibroblasts. Our results suggest a dysregulation of cholesterol processing in AD fibroblasts which may contribute to the pathogenesis of AD.

3.415 Distribution of myocilin, a glaucoma gene product, in human corneal fibroblasts
Wentz-Hunter, K., Shen, X. and Yue, B.Y.J.

*Mol. Vision., **9**, 308-314 (2003)*

Purpose: Myocilin is a gene linked to open-angle glaucomas. In this study, the expression and distribution of myocilin in corneal fibroblasts with or without dexamethasone (DEX) treatment were investigated.
Methods: Human corneal fibroblasts were treated with 100 nM DEX for 10-14 days. Immunofluorescence staining for myocilin was performed. Cell lysates and ultracentrifugation fractions were assessed by western blotting for distribution of myocilin and its possible association with various organelles. Staurosporine was used to induce apoptosis and apoptotic cells were detected using a monoclonal single stranded DNA antibody.
Results: By immunofluorescence, myocilin protein was found to distribute throughout the cytoplasm of corneal fibroblasts including perinuclear regions. Myocilin distribution overlapped to varying degrees with that of the Golgi complex, endoplasmic reticulum, and mitochondria. Subsequent examination by subcellular fractionation however revealed that myocilin, while co-sedimenting with the Golgi complex, lysosomes, and endoplasmic reticulum, did not fractionate or associate with mitochondria. On western blots, protein bands at approximately 66, 57, and 55 kDa were detected and the intensity of the bands was not affected by DEX treatment in corneal fibroblasts. Apoptosis was induced by staurosporine to a similar extent in both DEX-treated and untreated corneal cultures.
Conclusions: In corneal fibroblasts, myocilin expression is not enhanced by DEX treatment and the protein was not associated with mitochondria, in contrast to what were found in human trabecular meshwork (TM) cells. Such differences suggest that the expression and distribution of myocilin may be distinctive for TM cells and may explain why pathology with myocilin mutations is only evident in glaucoma even though myocilin is expressed ubiquitously in ocular and nonocular tissues.

3.416 Proteomic characterisation of neuronal sphingolipid-cholesterol microdomains: role in plasminogen activation
Ledesma, M.D., Da Silva, J.S., Schevchenko, A., Wilm, M. And Dotti, C.G.
*Brain Res., **987**, 107-116 (2003)*

Sorting of certain membrane proteins requires a mechanism involving rafts, protein–lipid complexes enriched in glycosphingolipids and cholesterol. These microdomains remain at the plasma membrane of different cell types and play a role in signal transduction. Although recent reports have begun to describe molecules associated with rafts, their protein composition remains largely unknown, especially in neuronal cells. To address this question, we have purified detergent-insoluble raft fractions (DRMs) from primary cultures of hippocampal neurons. Bidimensional gel analysis and pharmacological raft lipid manipulation allowed the identification of neuronal raft proteins and their characterisation by MALDI-TOF analysis. Enolases were found among the proteins identified and functional studies demonstrate their participation in plasminogen binding. We also show the specific enrichment in rafts of several other plasminogen binding molecules and the exclusive activation of plasminogen to the protease plasmin in these microdomains. These observations suggest that neuronal rafts may play, in addition to intracellular signaling, a role in extracellular/membrane protein proteolysis.

3.417 Characterization of the expression, intracellular localization, and replication complex association of the putative mouse hepatitis virus RNA-dependent RNA polymerase
Brockway, S.M., Clay, C.T., Lu, X.T. and Denison, M.R.
*J. Virol., **77(19)**, 10515-10527 (2003)*

Mouse hepatitis virus (MHV) RNA synthesis is mediated by a viral RNA-dependent RNA polymerase (RdRp) on membrane-bound replication complexes in the host cell cytoplasm. However, it is not known how the putative MHV RdRp (Pol) is targeted to and retained on cellular membranes. In this report, we show that a 100-kDa protein was stably detected by an anti-Pol antiserum as a mature product throughout the virus life cycle. Gradient fractionation and biochemical extraction experiments demonstrated that Pol was not an integral membrane protein but was tightly associated with membranes and coimmunoprecipitated with the replicase proteins 3CLpro, p22, and p12. By immunofluorescence confocal microscopy, Pol colocalized with viral proteins at replication complexes, distinct from sites of virion assembly, over the entire course of infection. To determine if Pol associated with cellular membranes in the absence of other viral factors, the *pol* domain of gene 1 was cloned and expressed in cells as a fusion with green fluorescent protein, termed Gpol. In Gpol-expressing cells that were infected with MHV, but not in mock-infected cells, Gpol relocalized from a diffuse distribution in the cytoplasm to punctate foci that colocalized with markers for replication complexes. Expression of Gpol deletion mutants established that the conserved enzymatic domains of Pol were dispensable for replication complex association, but a 38-

amino-acid domain in the RdRp unique region of Pol was required. This study demonstrates that viral or virus-induced factors are necessary for Pol to associate with membranes of replication complexes, and it identifies a defined region of Pol that may mediate its interactions with those factors.

3.418 Endoplasmic reticulum export of glycosyltransferases depends on interaction of a cytoplasmic dibasic motif with Sar1
Giraudo, C.G. and Maccioni, J.F.
*Mol. Biol. Cell, **14,** 3753-3766 (2003)*

Membrane proteins exit the endoplasmic reticulum (ER) in COPII-transport vesicles. ER export is a selective process in which transport signals present in the cytoplasmic tail (CT) of cargo membrane proteins must be recognized by coatomer proteins for incorporation in COPII vesicles. Two classes of ER export signals have been described for type I membrane proteins, the diacidic and the dihydrophobic motifs. Both motifs participate in the Sar1-dependent binding of Sec23p–Sec24p complex to the CTs during early steps of cargo selection. However, information concerning the amino acids in the CTs that interact with Sar1 is lacking. Herein, we describe a third class of ER export motif, [RK](X)[RK], at the CT of Golgi resident glycosyltransferases that is required for these type II membrane proteins to exit the ER. The dibasic motif is located proximal to the transmembrane border, and experiments of cross-linking in microsomal membranes and of binding to immobilized peptides showed that it directly interacts with the COPII component Sar1. Sar1GTP-bound to immobilized peptides binds Sec23p. Collectively, the present data suggest that interaction of the dibasic motif with Sar1 participates in early steps of selection of Golgi resident glycosyltransferases for transport in COPII vesicles.

3.419 Endostatin associates with lipid rafts and induces reorganisation of the actin cytoskeleton via down-regulation of RhoA activity
Wickström, S.A., Alitalo, K. and Keski-Oja, J.
*J. Biol. Chem., **278(39)**, 37895-37901 (2003)*

Endostatin, the C-terminal fragment of collagen XVIII, is a potent inhibitor of angiogenesis. Observations that endostatin inhibits endothelial cell migration and induces disassembly of the actin cytoskeleton provide putative cellular mechanisms for this effect. To understand the mechanisms of endostatin-induced intracellular signaling, we analyzed the association of recombinant endostatin with endothelial cell lipid rafts and the roles of its heparin- and integrin-binding properties in this interaction. We observed that a fraction of cell surface-bound endostatin partitioned in low density membrane raft fractions together with caveolin-1. Heparinase treatment of cells prevented the recruitment of endostatin to the lipid rafts but did not affect the association of endostatin with the non-raft fraction, whereas preincubation of endostatin with soluble $\alpha_5\beta_1$ integrin prevented the association of endostatin with the endothelial cell membrane. Endostatin treatment induced recruitment of $\alpha_5\beta_1$ integrin into the raft fraction via a heparan sulfate proteoglycan-dependent mechanism. Subsequently, through $\alpha_5\beta_1$ integrin, heparan sulfate, and lipid raft-mediated interactions, endostatin induced Src-dependent activation of p190RhoGAP with concomitant decrease in RhoA activity and disassembly of actin stress fibers and focal adhesions. These observations provide a cell biological mechanism, which plausibly explains the anti-angiogenic mechanisms of endostatin *in vivo*.

3.420 Phagosomes are competent organelles for antigen cross-presentation
Houde, M. et al
*Nature, **425**, 402-406 (2003)*

The ability to process microbial antigens and present them at the surface of cells is an important aspect of our innate ability to clear infections. It is generally accepted that antigens in the cytoplasm are loaded in the endoplasmic reticulum and presented at the cell surface on major histocompatibility complex (MHC) class I molecules, whereas peptides present in endo/phagocytic compartments are presented on MHC class II molecules. Despite the apparent segregation of the class I and class II pathways, antigens from intracellular pathogens including mycobacteria, *Escherichia coli*, *Salmonella typhimurium*, *Brucella abortus* and *Leishmania*, have been shown to elicit an MHC class-I-dependent $CD8^+$ T-cell response, a process referred to as cross-presentation. The cellular mechanisms allowing the cross-presentation pathway are poorly understood. Here we show that phagosomes display the elements and properties needed to be self-sufficient for the cross-presentation of exogenous antigens, a newly ascribed function linked to phagocytosis mediated by the endoplasmic reticulum.

3.421 Compartmentalization of integrin α6β4 signaling in lipid rafts
Gagnoux-Palacios, L. et al
*J. Cell Biol., **162(7)**, 1189-1196 (2003)*

Integrin α6ß4 signaling proceeds through Src family kinase (SFK)–mediated phosphorylation of the cytoplasmic tail of ß4, recruitment of Shc, and activation of Ras and phosphoinositide-3 kinase. Upon cessation of signaling, α6ß4 mediates assembly of hemidesmosomes. Here, we report that part of α6ß4 is incorporated in lipid rafts. Metabolic labeling in combination with mutagenesis indicates that one or more cysteine in the membrane-proximal segment of ß4 tail is palmitoylated. Mutation of these cysteines suppresses incorporation of α6ß4 in lipid rafts, but does not affect α6ß4-mediated adhesion or assembly of hemidesmosomes. The fraction of α6ß4 localized to rafts associates with a palmitoylated SFK, whereas the remainder does not. Ligation of palmitoylation-defective α6ß4 does not activate SFK signaling to extracellular signal–regulated kinase and fails to promote keratinocyte proliferation in response to EGF. Thus, compartmentalization in lipid rafts is necessary to couple the α6ß4 integrin to a palmitoylated SFK and promote EGF-dependent mitogenesis.

3.422 Mislocalization of membrane proteins associated with multidrug resistance in cisplastin-resistant cancer cell lines
Liang, X-J., Shen, D-W., Garfield, S. And Gottesman, M.M.
*Cancer Res., **63**, 5909-5916 (2003)*

The accumulation of [^{14}C]carboplatin and [^{3}H]methotrexate is reduced in single-step KB epidermoid adenocarcinoma (KB-CP) cells, which are cross-resistant to carboplatin, methotrexate, and sodium arsenite. In these KB-CP cells, multidrug resistance is accompanied by mislocalization of multidrug resistance associated protein (MRP) 1 and other membrane proteins such as folate-binding protein. MRP1 was not decreased in amount in single-step variants but accumulates in a cytoplasmic fraction, and its apparent molecular weight was altered probably because of reduced glycosylation in resistant cells. This low-density compartment was partially labeled with antibodies to lectin-GSII (a Golgi marker) and Bip/GRP78 (an endoplasmic reticulum marker). Pulse-chase labeling of MRP1 with ^{35}S-methionine and ^{35}S-cysteine and pulse-chase biotinylation of cell surface MRP1 suggests that membrane protein mislocalization is caused mainly by a defect of plasma membrane protein recycling, manifested also as a defect in acidification of lysosomes. The reduced accumulation of cytotoxic compounds in the KB-CP cells is presumed to result from the failure of carrier proteins and/or transporters to localize to the plasma membrane.

3.423 The major surface protease (MSP or GP63) of *Leishmania* sp. Biosynthesis, regulation of expression and function
Yao, C., Donelson, J.E. and Wilson, M.E.
*Mol. Biol. Parasitol., **132**, 1-16 (2003)*

Leishmania sp. are digenetic protozoa that cause an estimated 1.5–2 million new cases of leishmaniasis per year worldwide. Among the molecular factors that contribute to *Leishmania* sp. virulence and pathogenesis is the major surface protease, alternately called MSP, GP63, leishmanolysin, EC3.4.24.36, and PSP, which is the most abundant surface protein of leishmania promastigotes. Recent studies using gene knockout, antisense RNA and overexpression mutants have demonstrated a role for MSP in resistance of promastigotes to complement-mediated lysis and either a direct or indirect role in receptor-mediated uptake of leishmania. The *MSP* gene clusters in different *Leishmania* sp. include multiple distinct *MSP*s that tend to fall into three classes, which can be distinguished by their sequences and by their differential expression in parasite life stages. Regulated expression of *MSP* class gene products during the parasite life cycle occurs at several levels involving both mRNA and protein metabolism. In this review we summarize advances in MSP research over the past decade, including organization of the gene families, crystal structure of the protein, regulation of mRNA and protein expression, biosynthesis and possible functions. The MSPs exquisitely demonstrate the multiple levels of post-transcriptional gene regulation that occur in *Leishmania* sp. and other trypanosomatid protozoa.

3.424 APP processing is regulated by cytoplasmic phosphorylation
Lee, M-S. et al
*J. Cell Biol., **163(1)**, 83-95 (2003)*

Amyloid-ß peptide (Aß) aggregate in senile plaque is a key characteristic of Alzheimer's disease (AD). Here, we show that phosphorylation of amyloid precursor protein (APP) on threonine 668 (P-APP) may play a role in APP metabolism. In AD brains, P-APP accumulates in large vesicular structures in afflicted hippocampal pyramidal neurons that costain with antibodies against endosome markers and the ß-secretase, BACE1. Western blot analysis reveals increased levels of T668-phosphorylated APP COOH-terminal fragments in hippocampal lysates from many AD but not control subjects. Importantly, P-APP cofractionates with endosome markers and BACE1 in an iodixanol gradient and displays extensive colocalization with BACE1 in rat primary cortical neurons. Furthermore, APP COOH-terminal fragments generated by BACE1 are preferentially phosphorylated on T668 verses those produced by α-secretase. The production of Aß is significantly reduced when phosphorylation of T668 is either abolished by mutation or inhibited by T668 kinase inhibitors. Together, these results suggest that T668 phosphorylation may facilitate the BACE1 cleavage of APP to increase Aß generation.

3.425 **Functional γ-secretase complex assembly in Golgi/*trans*-Golgi network: interactions among presenilin, nicastrin, Aph1, Pen-2, and γ-secreatase substrates**
Baulac, S. et al
Neurobiology of Disease, ***14***, *194-204 (2003)*

γ-Secretase is a proteolytic complex whose substrates include Notch, β-amyloid precursor protein (APP), and several other type I transmembrane proteins. Presenilin (PS) and nicastrin are known components of this high-molecular-weight complex, and recent genetic screens in invertebrates have identified two additional gene products, Aph1 and Pen-2, as key factors in γ-secretase activity. Here, we examined the interaction of the components of the γ-secretase complex in Chinese hamster ovary cells stably expressing human forms of APP, PS1, Aph1, and Pen-2. Subcellular fractionation of membrane vesicles and subsequent coimmunoprecipitation of individual γ-secretase components revealed that interactions among all proteins occurred in the Golgi/*trans*-Golgi network (TGN) compartments. Furthermore, incubation of the Golgi/TGN-enriched vesicles resulted in de novo generation of amyloid β-protein and APP intracellular domain. Immunofluorescent staining of the individual γ-secretase components supported our biochemical evidence that the γ-secretase components assemble into the proteolytically active γ-secretase complex in the Golgi/TGN compartment.

3.426 **The conversion of apoB100 low density lipoprotein/high density lipoprotein particles to apoB100 very low density lipoproteins in response to oleic acid occurs in the endoplasmic reticulum and not in the Golgi in Mca RH7777 cells**
Yamaguchi, J., Gamble, M.V., Conlon, D., Liang, J-S. and Ginsberg, H.N.
J. Biol. Chem., ***278(43)***, *42643-42651 (2003)*

The site where bulk lipid is added to apoB100 low density lipoproteins (LDL)/high density lipoproteins (HDL) particles to form triglyceride-enriched very low density lipoproteins (VLDL) has not been identified definitively. We employed several strategies to address this question. First, McA RH7777 cells were pulse-labeled for 20 min with [^{35}S]methionine/cysteine and chased for 1 h (Chase I) to allow study of newly synthesized apoB100 LDL/HDL remaining in the endoplasmic reticulum (ER). After Chase I, cells were incubated for another hour (C2) with/without brefeldin A (BFA) and nocodazole (Noc) (to block ER to Golgi trafficking) and with/without oleic acid (OA). OA treatment alone during C2 increased VLDL secretion. This was prevented by the addition of BFA/Noc in C2. When C2 media were replaced by control media for another 1-h chase (C3), VLDL formed during OA treatment in C2 were secreted into C3 medium. Thus, OA-induced conversion of apoB100 LDL/HDL to VLDL during C2 occurred in the ER. Next, newly synthesized apoB100 lipoproteins were trapped in the Golgi by treatment with Noc and monensin during Chase I (C1), and C2 was carried out in the presence of BFA/Noc with/without OA and without monensin. Under these conditions, OA treatment during C2 did not stimulate VLDL secretion. The same pulse/chase protocols were followed by **iodixanol** subcellular fractionation, extraction of lipoproteins from ER and Golgi, and sucrose gradient separation of extracted lipoproteins. Cells treated with BFA/Noc and OA in C2 had VLDL in the ER. In the absence of OA, only LDL/HDL were present in the ER. The density of Golgi lipoproteins in these cells was not affected by OA. Similar results were obtained when ER were immuno-isolated with anti-calnexin antibodies. In conclusion, apoB100 bulk lipidation, resulting in conversion of LDL/HDL to VLDL, can occur in the ER, but not in the Golgi, in McA RH7777 cells.

3.427 **Pressure-induced differential regulation of the two tryptophan permeases Tat1 and Tat2 by ubiquitin ligase Rsp5 and its binding proteins, Bu11 and Bu12**
Abe, F. and Iida, H.

Mol. Cell. Biol., ***23(21)***, *7566-7584 (2003)*

Tryptophan uptake appears to be the Achilles' heel in yeast physiology, since under a variety of seemingly diverse toxic conditions, it becomes the limiting factor for cell growth. When growing cells of *Saccharomyces cerevisiae* are subjected to high hydrostatic pressure, tryptophan uptake is down-regulated, leading to cell cycle arrest in the G_1 phase. Here we present evidence that the two tryptophan permeases Tat1 and Tat2 are differentially regulated by Rsp5 ubiquitin ligase in response to high hydrostatic pressure. Analysis of high-pressure growth mutants revealed that the *HPG1* gene was allelic to *RSP5*. The *HPG1* mutation or the *bul1*Δ *bul2*Δ double mutation caused a marked increase in the steady-state level of Tat2 but not of Tat1, although both permeases were degraded at high pressure in an Rsp5-dependent manner. There were marked differences in subcellular localization. Tat1 localized predominantly in the plasma membrane, whereas Tat2 was abundant in the internal membranes. Moreover, Tat1 was associated with lipid rafts, whereas Tat2 localized in bulk lipids. Surprisingly, Tat2 became associated with lipid rafts upon the occurrence of a ubiquitination defect. These results suggest that ubiquitination is an important determinant of the localization and regulation of these tryptophan permeases. Determination of the activation volume ($\Delta V^{\neq}$) for Tat1- and Tat2-mediated tryptophan uptake (89.3 and 50.8 ml/mol, respectively) revealed that both permeases are highly sensitive to membrane perturbation and that Tat1 rather than Tat2 is likely to undergo a dramatic conformational change during tryptophan import. We suggest that hydrostatic pressure is a unique tool for elucidating the dynamics of integral membrane protein functions as well as for probing lipid microenvironments where they localize.

3.428 The AP-1A and AP1B clathrin adaptor complexes define biochemically and functionally distinct membrane domains

Fölsch, H., Pypaert, M., Maday, S., Pelletier, L. and Mellman, I.
J. Cell Biol., ***163(2)***, *351-362 (2003)*

Most epithelial cells contain two AP-1 clathrin adaptor complexes. AP-1A is ubiquitously expressed and involved in transport between the TGN and endosomes. AP-1B is expressed only in epithelia and mediates the polarized targeting of membrane proteins to the basolateral surface. Both AP-1 complexes are heterotetramers and differ only in their 50-kD μ1A or μ1B subunits. Here, we show that AP-1A and AP-1B, together with their respective cargoes, define physically and functionally distinct membrane domains in the perinuclear region. Expression of AP-1B (but not AP-1A) enhanced the recruitment of at least two subunits of the exocyst complex (Sec8 and Exo70) required for basolateral transport. By immunofluorescence and cell fractionation, the exocyst subunits were found to selectively associate with AP-1B–containing membranes that were both distinct from AP-1A–positive TGN elements and more closely apposed to transferrin receptor–positive recycling endosomes. Thus, despite the similarity of the two AP-1 complexes, AP-1A and AP-1B exhibit great specificity for endosomal transport versus cell polarity.

3.429 Epstein-Barr virus latent membrane protein 2A activates β-catenin signaling in epithelial cells

Morrison, J.A., Klingelhutz, A.J. and Raab-Traub, N.
J. Virol., ***77(22)***, *12276-12284 (2003)*

The Epstein-Barr virus (EBV) latent membrane protein 2A (LMP2A) functions to maintain latency in EBV-infected B lymphocytes. Although LMP2A is nonessential for the immortalization of B lymphocytes by EBV, its expression in B lymphocytes prevents viral reactivation by blocking B-cell receptor activation and signaling. LMP2A also provides an antiapoptotic signal in transgenic mice that express LMP2A in B lymphocytes. LMP2A activates phosphatidylinositol 3-kinase (PI3K) and the serine/threonine kinase Akt in lymphocytes and epithelial cells. Here we show that EBV LMP2A activates the PI3K and ß-catenin signaling pathways in telomerase-immortalized human foreskin keratinocytes (HFK). LMP2A activated Akt in a PI3K-dependent manner, and the downstream Akt targets glycogen synthase kinase 3ß (GSK3ß) and the Forkhead transcription factor FKHR were phosphorylated and inactivated in LMP2A-expressing HFK cells. GSK3ß is a negative regulator of the Wnt signaling pathway, and inactivation of GSK3ß by LMP2A signaling led to stabilization of ß-catenin, the central oncoprotein of Wnt signaling. In LMP2A-expressing cells, ß-catenin accumulated in the cytoplasm and translocated into the nucleus via a two-step mechanism. The cytoplasmic accumulation of ß-catenin downstream of LMP2A was independent of PI3K signaling, whereas its nuclear translocation was dependent on PI3K signaling. In the nucleus, ß-catenin activated a reporter responsive to T-cell factor, and this activation was augmented by LMP2A coexpression. The Wnt pathway is inappropriately activated in 90% of colon cancers and is dysregulated in several other cancers, and these data suggest that activation of this pathway by LMP2A may contribute to the generation of EBV-associated cancers.

3.430 Function, expression and localization of annexin A7 in platelets and red blood cells: insights derived from an annexin A7 mutant mouse
Herr, C. et al
BMC Biochem., ***4(8)****, 1-11 (2003)*

Annexin A7 is a Ca^{2+}- and phospholipid-binding protein expressed as a 47 and 51 kDa isoform, which is thought to be involved in membrane fusion processes. Recently the 47 kDa isoform has been identified in erythrocytes where it was proposed to be a key component in the process of the Ca^{2+}-dependent vesicle release, a process with which red blood cells might protect themselves against an attack by for example complement components.
The role of annexin A7 in red blood cells was addressed in erythrocytes from *anxA7*$^{-/-}$ mice. Interestingly, the Ca^{2+}-mediated vesiculation process was not impaired. Also, the membrane organization appeared not to be disturbed as assessed using gradient fractionation studies. Instead, lack of annexin A7 led to an altered cell shape and increased osmotic resistance of red blood cells. Annexin A7 was also identified in platelets. In these cells its loss led to a slightly slower aggregation velocity which seems to be compensated by an increased number of platelets. The results appear to rule out an important role of annexin A7 in membrane fusion processes occurring in red blood cells. Instead the protein might be involved in the organization of the membrane cytoskeleton. Red blood cells may represent an appropriate model to study the role of annexin A7 in cellular processes.

We have demonstrated the presence of both annexin A7 isoforms in red blood cells and the presence of the small isoform in platelets. In both cell types the loss of annexin A7 impairs cellular functions. The defects observed are however not compatible with a crucial role for annexin A7 in membrane fusion processes in these cell types.

3.431 Vesicular localization and activity-dependent trafficking of presynaptic choline transporters
Ferguson, S.M. et al
J. Neurosci., ***23(30)****, 9697-9709 (2003)*

Presynaptic synthesis of acetylcholine (ACh) requires a steady supply of choline, acquired by a plasma membrane, hemicholinium-3-sensitive (HC-3) choline transporter (CHT). A significant fraction of synaptic choline is recovered from ACh hydrolyzed by acetylcholinesterase (AChE) after vesicular release. Although antecedent neuronal activity is known to dictate presynaptic CHT activity, the mechanisms supporting this regulation are unknown. We observe an exclusive localization of CHT to cholinergic neurons and demonstrate that the majority of CHTs reside on small vesicles within cholinergic presynaptic terminals in the rat and mouse brain. Furthermore, immunoisolation of presynaptic vesicles with multiple antibodies reveals that CHT-positive vesicles carry the vesicular acetylcholine transporter (VAChT) and synaptic vesicle markers such as synaptophysin and Rab3A and also contain acetylcholine. Depolarization of synaptosomes evokes a Ca^{2+}-dependent botulinum neurotoxin C-sensitive increase in the V_{max} for HC-3-sensitive choline uptake that is accompanied by an increase in the density of CHTs in the synaptic plasma membrane. Our study leads to the novel hypothesis that CHTs reside on a subpopulation of synaptic vesicles in cholinergic terminals that can transit to the plasma membrane in response to neuronal activity to couple levels of choline re-uptake to the rate of ACh release.

3.432 Visualization of protein compartmentation within the plasma membrane of living yeast cells
Malinska, K., Malinsky, J., Opekarova, M and Tanner, W.
Mol. Biol. Cell., ***14(11)****, 4427-4436 (2003)*

Different distribution patterns of the arginine/H^+ symporter Can1p, the H^+ plasma membrane ATPase Pma1p, and the hexose transport facilitator Hxt1p within the plasma membrane of living *Saccharomyces cerevisiae* cells were visualized using fluorescence protein tagging of these proteins. Although Hxt1p-GFP was evenly distributed through the whole cell surface, Can1p-GFP and Pma1p-GFP were confined to characteristic subregions in the plasma membrane. Pma1p is a well-documented raft protein. Evidence is presented that Can1p, but not Hxt1p, is exclusively associated with lipid rafts, too. Double labeling experiments with Can1p-GFP– and Pma1p-RFP–containing cells demonstrate that these proteins occupy two different nonoverlapping membrane microdomains. The size of Can1p-rich (Pma1p-poor) areas was estimated to 300 nm. These domains were shown to be stable in growing cells for >30 min. To our knowledge, this is the first observation of a cell polarization-independent lateral compartmentation in the plasma membrane of a living cell.

3.433 Inhibition of heme biosynthesis prevents transcription of iron uptake genes in yeast
Crisp, R.J. et al
J. Biol. Chem., ***278(46)***, *45499-45506 (2003)*

Yeast are capable of modifying their metabolism in response to environmental changes. We investigated the activity of the oxygen-dependent high-affinity iron uptake system of *Saccharomyces cerevisiae* under conditions of heme depletion. We found that the absence of heme, due to a deletion in the gene that encodes δ-aminolevulinic acid synthase (*HEM1*), resulted in decreased transcription of genes belonging to both the iron and copper regulons, but not the zinc regulon. Decreased transcription of the iron regulon was not due to decreased expression of the iron sensitive transcriptional activator Aft1p. Expression of the constitutively active allele *AFT1-1*^{up} was unable to induce transcription of the high affinity iron uptake system in heme-depleted cells. We demonstrated that under heme-depleted conditions, Aft1p-GFP was able to cycle normally between the nucleus and cytosol in response to cytosolic iron. Despite the inability to induce transcription under low iron conditions, chromatin immunoprecipitation demonstrated that Aft1p binds to the *FET3* promoter in the absence of heme. Finally, we provide evidence that under heme-depleted conditions, yeast are able to regulate mitochondrial iron uptake and do not accumulate pathologic iron concentrations, as is seen when iron-sulfur cluster synthesis is disrupted.

3.434 Syndecan-1 transmembrane and extracellular domains have unique and distinct roles in cell spreading
McQuade, K.J. and Repraeger, A.C.
J. Biol. Chem., ***278(47)***, *46607-46615 (2003)*

Raji cells expressing syndecan-1 (Raji-S1) adhere and spread when plated on heparan sulfate-binding extracellular matrix ligands or monoclonal antibody 281.2, an antibody directed against the syndecan-1 extracellular domain. Cells plated on monoclonal antibody 281.2 initially extend a broad lamellipodium, a response accompanied by membrane ruffling at the cell margin. Membrane ruffling then becomes polarized, leading to an elongated cell morphology. Previous work demonstrated that the syndecan-1 cytoplasmic domain is not required for these activities, suggesting important roles for the syndecan-1 transmembrane and/or extracellular domains in the assembly of a signaling complex necessary for spreading. Work described here demonstrates that truncation of the syndecan-1 extracellular domain does not affect the initial lamellipodial extension in the Raji-S1 cells but does inhibit the active membrane ruffling that is necessary for cell polarization. Replacement of the entire syndecan-1 transmembrane domain with leucine residues completely blocks the cell spreading. These data demonstrate that the syndecan-1 transmembrane and extracellular domains have important but distinct roles in Raji-S1 cell spreading; the extracellular domain mediates an interaction that is necessary for dynamic cytoskeletal rearrangements whereas an interaction of the transmembrane domain is required for the initial spreading response.

3.435 Raft disorganization leads to reduced plasmin activity in Alzheimer's disease brains
Ledesma, M.D. et al
EMBO Reports, ***4(12)***, *1190-1196 (2003)*

The serine protease plasmin can efficiently degrade amyloid peptide in vitro, and is found at low levels in the hippocampus of patients with Alzheimer's disease (AD). The cause of such paucity remains unknown. We show here that the levels of total brain plasminogen and plasminogen-binding molecules are normal in these brain samples, yet plasminogen membrane binding is greatly reduced. Biochemical analysis reveals that the membranes of these brains have a mild, still significant, cholesterol reduction compared to age-matched controls, and anomalous raft microdomains. This was reflected by the loss of raft-enriched proteins, including plasminogen-binding and -activating molecules. Using hippocampal neurons in culture, we demonstrate that removal of a similar amount of membrane cholesterol is sufficient to induce raft disorganization, leading to reduced plasminogen membrane binding and low plasmin activity. These results suggest that brain raft alterations may contribute to AD by rendering the plasminogen system inefficient.

3.436 Novel cadherin-related membrane proteins, alcadeins, enhance the X11-like protein-mediated stabilization of amyloid β-protein precursor metabolism
Araki, Y. et al
J. Biol.Chem., ***278(49)***, *49448-49458 (2003)*

Previously we found that X11-like protein (X11L) associates with amyloid β-protein precursor (APP). X11L stabilizes APP metabolism and suppresses the secretion of the amyloid β-protein (Aβ) that are the pathogenic agents of Alzheimer's disease (AD). Here we found that Alcadein (Alc), a novel membrane protein family that contains cadherin motifs and originally reported as calsyntenins, also interacted with X11L. Alc was abundant in the brain and occurred in the same areas of the brain as X11L. X11L could simultaneously associate with APP and Alc, resulting in the formation of a tripartite complex in brain. The tripartite complex stabilized intracellular APP metabolism and enhanced the X11L-mediated suppression of Aβ secretion that is due to the retardation of intracellular APP maturation. X11L and Alc also formed another complex with C99, a carboxyl-terminal fragment of APP cleaved at the β-site (CTFβ). The formation of the Alc·X11L·C99 complex inhibited the interaction of C99 with presenilin, which strongly suppressed the γ-cleavage of C99. In AD patient brains, Alc and APP were particularly colocalized in dystrophic neurites in senile plaques. Deficiencies in the X11L-mediated interaction between Alc and APP and/or CTFβ enhanced the production of Aβ, which may be related to the development or progression of AD.

3.437 RGS16 inhibits signaling through the Gα13-Rho
Johnson, E.N. et al
*Nature Cell Biol., **5(12)**, 1095-1103 (2003)*

Gα13 stimulates the guanine nucleotide exchange factors (GEFs) for Rho, such as p115Rho-GEF[1]. Activated Rho induces numerous cellular responses, including actin polymerization, serum response element (SRE)-dependent gene transcription and transformation[2]. p115Rho-GEF contains a Regulator of G protein Signalling domain (RGS box) that confers GTPase activating protein (GAP) activity towards Gα12 and Gα13 (ref. 3). In contrast, classical RGS proteins (such as RGS16 and RGS4) exhibit RGS domain-dependent GAP activity on Gαi and Gαq, but not Gα12 or Gα13 (ref 4). Here, we show that RGS16 inhibits Gα13-mediated, RhoA-dependent reversal of stellation and SRE activation. The RGS16 amino terminus binds Gα13 directly, resulting in translocation of Gα13 to detergent-resistant membranes (DRMs) and reduced p115Rho-GEF binding. RGS4 does not bind Gα13 or attenuate Gα13-dependent responses, and neither RGS16 nor RGS4 affects Gα12-mediated signalling. These results elucidate a new mechanism whereby a classical RGS protein regulates Gα13-mediated signal transduction independently of the RGS box.

3.438 The lack of annexin A7 affects functions of primary astrocytes
Clemen, C.S., Herr, C., Hövelmeyer, N. and Noegel, A.A.
*Exp. Cell Res., **291**, 406-414 (2003)*

Annexin A7 is a Ca^{2+}- and phospholipid-binding protein, which is thought to function in membrane organization and Ca^{2+}-dependent signaling processes. It localizes to different cellular compartments and exists in a 47- and 51-kDa isoform with the large isoform being expressed in brain, skeletal, and heart muscle. In human temporal brain annexin A7 was found exclusively in astroglial cells. As astrocytes are thought to play key roles in several processes of the brain we focused on Ca^{2+}-dependent signaling processes and astrocyte proliferation. Primary astrocytes from an *anxA7*$^{-/-}$ mouse exhibited an increased velocity of mechanically induced astrocytic Ca^{2+} waves as compared to wild type. We also observed a remarkably increased proliferation rate in cultured mutant astrocytes. A search for annexin A7 binding partners with advanced biochemical methods confirmed sorcin as the major binding protein. However, in vivo GFP-tagged annexin A7 and sorcin appeared to redistribute mainly independently from each other in wild type and in mutant astrocytes. Our results favor an involvement of annexin A7 in Ca^{2+}-dependent signaling or Ca^{2+} homeostasis in astrocytes.

3.439 Subcellular localization and regulation of coenzyme A synthetase
Zhyvoloup, A. et al
*J. Biol. Chem., **278(50)**, 50316-50321 (2003)*

CoA synthase mediates the last two steps in the sequence of enzymatic reactions, leading to CoA biosynthesis. We have recently identified cDNA for CoA synthase and demonstrated that it encodes a bifunctional enzyme possessing 4'-phosphopantetheine adenylyltransferase and dephospho-CoA kinase activities. Molecular cloning of CoA synthase provided us with necessary tools to study subcellular localization and the regulation of this bifunctional enzyme. Transient expression studies and confocal microscopy allowed us to demonstrate that full-length CoA synthase is associated with the mitochondria,

whereas the removal of the N-terminal region relocates the enzyme to the cytosol. In addition, we showed that the N-terminal sequence of CoA synthase (amino acids 1–29) exhibits a hydrophobic profile and targets green fluorescent protein exclusively to mitochondria. Further analysis, involving subcellular fractionation and limited proteolysis, indicated that CoA synthase is localized on the mitochondrial outer membrane. Moreover, we demonstrate for the first time that phosphatidylcholine and phosphatidylethanolamine, which are the main components of the mitochondrial outer membrane, are potent activators of both enzymatic activities of CoA synthase *in vitro*. Taken together, these data provide the evidence that the final stages of CoA biosynthesis take place on mitochondria and the activity of CoA synthase is regulated by phospholipids.

3.440 Yeast homotypic vacuole fusion requires the Ccz1-Mon1 complex during the tethering/docking stage
Wang, C-W., Stromhaug, P.E., Kauffman, E.J., Weisman, L.S. and Klionsky, D.J.
J. Cell Biol., ***163(5)***, *973-985 (2003)*

The function of the yeast lysosome/vacuole is critically linked with the morphology of the organelle. Accordingly, highly regulated processes control vacuolar fission and fusion events. Analysis of homotypic vacuole fusion demonstrated that vacuoles from strains defective in the *CCZ1* and *MON1* genes could not fuse. Morphological evidence suggested that these mutant vacuoles could not proceed to the tethering/docking stage. Ccz1 and Mon1 form a stable protein complex that binds the vacuole membrane. In the absence of the Ccz1–Mon1 complex, the integrity of vacuole SNARE pairing and the unpaired SNARE class C Vps/HOPS complex interaction were both impaired. The Ccz1–Mon1 complex colocalized with other fusion components on the vacuole as part of the cis-SNARE complex, and the association of the Ccz1–Mon1 complex with the vacuole appeared to be regulated by the class C Vps/HOPS complex proteins. Accordingly, we propose that the Ccz1–Mon1 complex is critical for the Ypt7-dependent tethering/docking stage leading to the formation of a trans-SNARE complex and subsequent vacuole fusion.

3.441 Active PIKfyve associates with and promotes the membrane attachment of the late endosome-to-*trans*-Golgi network transport factor Rab9 effector p40
Ikonomov, O.C. et al
J. Biol. Chem., ***278(51)***, *50863-50871 (2003)*

PIKfyve, a kinase that displays specificity for phosphatidylinositol (PtdIns), PtdIns 3-phosphate (3-P), and proteins, is important in multivesicular body/late endocytic function. Enzymatically inactive PIKfyve mutants elicit enormous dilation of late endocytic structures, suggesting a role for PIKfyve in endosome-to-*trans*-Golgi network (TGN) membrane retrieval. Here we report that p40, a Rab9 effector reported previously to bind Rab9-GTP and stimulate endosome-to-TGN transport, interacts with PIKfyve as determined by yeast two-hybrid assays, glutathione *S*-transferase (GST) pull-down assays, and co-immunoprecipitation in doubly transfected HEK293 cells. The interaction engages the PIKfyve chaperonin domain and four out of the six C-terminally positioned kelch repeats in p40. Differential centrifugation in a HEK293 cell line, stably expressing PIKfyve^{WT}, showed the membrane-associated immunoreactive p40 co-sedimenting with PIKfyve in the high speed pellet (HSP) fraction. Remarkably, similar analysis in a HEK293 cell line stably expressing dominant-negative kinase-deficient PIKfyve^{K1831E} demonstrated a marked depletion of p40 from the HSP fraction. GST-p40 failed to specifically associate with the PIKfyve lipid products PtdIns 5-P and PtdIns 3,5-P_2 in a liposome binding assay but was found to be an *in vitro* substrate of the PIKfyve serine kinase activity. A band with the p40 electrophoretic mobility was found to react with a phosphoserine-specific antibody mainly in the PIKfyve^{WT}-containing fractions obtained by density gradient sedimentation of total membranes from PIKfyve^{WT}-expressing HEK293 cells. Together these results identify the Rab9 effector p40 as a PIKfyve partner and suggest that p40-PIKfyve interaction and the subsequent PIKfyve-catalyzed p40 phosphorylation anchor p40 to discrete membranes facilitating late endosome-to-TGN transport.

3.442 Generation of the β-amyloid peptide and the amyloid percursor protein C-terminal fragment γ are potentiated by FE65L1
Chang, Y. et al
J. Biol. Chem., ***278(51)***, *511000-51107 (2003)*

Members of the FE65 family of adaptor proteins, FE65, FE65L1, and FE65L2, bind the C-terminal region of the amyloid precursor protein (APP). Overexpression of FE65 and FE65L1 was previously reported to

increase the levels of α-secretase-derived APP (APPsα). Increased β-amyloid (Aβ) generation was also observed in cells showing the FE65-dependent increase in APPsα. To understand the mechanism for the observed increase in both Aβ and APPsα given that α-secretase cleavage of a single APP molecule precludes Aβ generation, we examined the effects of FE65L1 overexpression on APP C-terminal fragments (APP CTFs). Our data show that FE65L1 potentiates γ-secretase processing of APP CTFs, including the amyloidogenic CTF C99, accounting for the ability of FE65L1 to increase generation of APP C-terminal domain and Aβ40. The FE65L1 modulation of these processing events requires binding of FE65L1 to APP and APP CTFs and is not because of a direct effect on γ-secretase activity, because Notch intracellular domain generation is not altered by FE65L1. Furthermore, enhanced APP CTF processing can be detected in early endosome vesicles but not in endoplasmic reticulum or Golgi membranes, suggesting that the effects of FE65L1 occur at or near the plasma membrane. Finally, although FE65L1 increases APP C-terminal domain production, it does not mediate the APP-dependent transcriptional activation observed with FE65.

3.443 Rat liver bile acid CoA:amino acid *N*-acyltransferase: expression, characterization, and peroxisomal localization

He, D., Barnes, S. and Falany, C.N.
J. Lipid Res., ***44****, 2242-2249 (2003)*

Bile acid CoA:amino acid *N*-acyltransferase (BAT) is responsible for the amidation of bile acids with the amino acids taurine and glycine. Rat liver BAT (rBAT) cDNA was isolated from a rat liver λZAP cDNA library and expressed in Sf9 insect cells using a baculoviral vector. rBAT displayed 65% amino acid sequence homology with human BAT (hBAT) and 85% homology with mouse BAT (mBAT). Similar to hBAT, expressed rBAT was capable of forming both taurine and glycine conjugates with cholyl-CoA. mBAT, which is highly homologous to rBAT, forms only taurine conjugated bile acids (**Falany, C. N., H. Fortinberry, E. H. Leiter, and S. Barnes.** 1997. Cloning and expression of mouse liver bile acid CoA: Amino acid N-acyltransferase. *J. Lipid Res.* **38:** 86–95). Immunoblot analysis of rat tissues detected rBAT only in rat liver cytosol following homogenization and ultracentrifugation. Subcellular localization of rBAT detected activity and immunoreactive protein in both cytosol and isolated peroxisomes. Rat bile acid CoA ligase (rBAL), the enzyme responsible for the formation of bile acid CoA esters, was detected only in rat liver microsomes. Treatment of rats with clofibrate, a known peroxisomal proliferator, significantly induced rBAT activity, message, and immunoreactive protein in rat liver. Peroxisomal membrane protein-70, a marker for peroxisomes, was also induced by clofibrate, whereas rBAL activity and protein amount were not affected.
In summary, rBAT is capable of forming both taurine and glycine bile acid conjugates and the enzyme is localized primarily in peroxisomes in rat liver.

3.444 Activation of nuclear factor-κB p50 homodimer/Bcl-3 complexes in nasapharyngeal carcinoma

Thornburg, N.J., oathmanathan, R. and Raab-Traub, N.
Cancer. Res., ***63****, 8293-8301 (2003)*

EBV latent infection is associated with the development of lymphoid and epithelial malignancies such as nasopharyngeal carcinoma (NPC). The EBV latent membrane protein 1 (LMP1) acts as a constitutively active tumor necrosis factor receptor and activates cellular signaling pathways such as c-Jun-NH_2-terminal kinase, cdc42, Akt, and nuclear factor (NF)-κB. In epithelial cells, two regions of LMP1 induce specific forms of NF-κB. COOH-terminal activating region 2 only activates p52/p65 dimers, whereas COOH-terminal activating region 1 activates p50/p50, p50/p52, and p52/p65 dimers and also uniquely up-regulates the epidermal growth factor receptor (EGFR) at the mRNA level. Deregulation of specific NF-κB members is associated with the development of many cancers. In this study, the status of NF-κB activation was investigated in NPC to determine which NF-κB dimers may contribute to the development of NPC. Electrophoretic mobility shift assay, immunoblot, ELISA, and immunohistochemistry data demonstrate that in NPC, NF-κB p50 homodimers are specifically activated, and this activation is not dependent on LMP1 expression. Coimmunoprecipitation assays indicate that homodimers are bound to the transcriptional coactivator Bcl-3, and chromatin immunoprecipitation indicates that this complex is bound to NF-κB consensus motifs within the *egfr* promoter in NPC. The discrete yet striking NF-κB p50 activation in NPC suggests that p50/p50 homodimers may be important factors in the development of NPC and may contribute to oncogenesis through transcriptional up-regulation of target genes through their interaction with Bcl-3.

3.445 Downregulation of caveolin-1 function by EGF leads to the loss of E-cadherin, increased transcriptional activity of β-catenin, and enhanced tumor cell invasion
Lu, Z., Ghosh, S., Wang, Z. and Hunter, T.
*Cancer Cell, **4**, 499-515 (2003)*

EGF receptor (EGFR) overexpression correlates with metastasis in a variety of carcinomas, but the underlying mechanisms are poorly understood. We demonstrated that EGF disrupted cell-cell adhesion and caused epithelial-to-mesenchymal transition (EMT) in human tumor cells overexpressing EGFR, and also induced caveolin-dependent endocytosis of E-cadherin, a cell-cell adhesion protein. Chronic EGF treatment resulted in transcriptional downregulation of caveolin-1 and induction of the transcriptional repressor Snail, correlating with downregulation of E-cadherin expression. Caveolin-1 downregulation enhanced β-catenin-TCF/LEF-1 transcriptional activity in a GSK-3β-independent manner. Antisense RNA-mediated reduction of caveolin-1 expression in EGFR-overexpressing tumor cells recapitulated these EGF-induced effects and enhanced invasion into collagen gels. We propose that EGF-induced negative regulation of caveolin-1 plays a central role in the complex cellular changes leading to metastasis.

3.446 Src signaling links mediators of inflammation to Cx43 gap junction channels in primary and transformed CFTR-expressing airway cells
Huang, S. et al
*Cell Comm. and Aadhesion, **10**, 279-285 (2003)*

Dysfunction of the cystic fibrosis transmembrane conductance regulator (CFTR) is associated with recurrent pulmonary infections and inflammation. We previously reported that tumor necrosis factor (TNF)-f decreases gap junction connectivity in cell lines derived from the airway epithelium of non-cystic fibrosis (non-CF) subjects, a mechanism that was defective in cells derived from CF patients, and identified the tyrosine kinase c-Src as a possible bridge between TNF-f and Cx43. To examine whether this modulation also takes place in primary epithelial cells, the functional expression of Cx43 was studied in non-CF and CF airway cells, obtained from surgical polypectomies and turbinectomies, which were grown either on culture dishes or permeable filters. Expression of Cx43 was detected by immunofluorescence on cells grown under both culture conditions. Non-CF and CF airway cells also showed intercellular diffusion of Lucifer Yellow. Dye coupling was rapidly abolished in non-CF cells in the presence of TNF-f, lipopolysaccharide and lysophosphatidic acid, and could be prevented by tyrphostin47, an inhibitor of Src tyrosine kinases. This down-regulation, however, was not detected in CF airway cells. These data indicate that CFTR dysfunction is associated with altered Src signaling, resulting in the persistence of gap junction connectivity in primary and transformed CF airway cells.

3.447 Large clusters of α7-containing nicotinic acetylcholine receptors on chick spinal cord neurons
Roth, A.L. and Berg, D.K.
*J. Comp. Neurol., **465**, 195-204 (2003)*

Nicotinic acetylcholine receptors containing the α7 gene product are widely expressed in the nervous system and have high calcium permeabilities that allow them to influence numerous calcium-dependent processes. Though often found at presynaptic locations, where they enhance transmitter release, the receptors can also occupy postsynaptic sites. Highest levels have been reported for chick ciliary ganglion neurons, where the postsynaptic receptors are concentrated on somatic spines arranged in clumps and appear as large receptor clusters. We show here that subpopulations of chick spinal cord neurons also express high levels of α7-containing receptors and arrange them in large clusters. The populations include peripheral motoneurons, presumptive preganglionic neurons, neurons adjacent to the lateral motor column, and possible interneurons in the ventral horn. In many cases, the receptor clusters codistribute with filamentous actin, as do clusters on ciliary ganglion neurons, where the actin represents a somatic spine constituent. In other respects, the spinal cord clusters differ. Those on motoneurons codistribute with the actin-associated component drebrin, as do the clusters on ciliary ganglion neurons, but the clusters on preganglionic neurons do not. Preganglionic neurons do, however, stain for lipid raft components as found for ciliary ganglion neurons, where the rafts embed the receptor-enriched spines. The results demonstrate that CNS neurons can configure α7-containing nicotinic receptors into large clusters but also suggest that the clusters are not likely to reflect a common molecular substructure on all neurons.

3.448 Lipid rafts: bringing order to chaos
Pike, L.J.
*J. Lipid Res., **44**, 655-667 (2003)*

Lipid rafts are subdomains of the plasma membrane that contain high concentrations of cholesterol and glycosphingolipids. They exist as distinct liquid-ordered regions of the membrane that are resistant to extraction with nonionic detergents. Rafts appear to be small in size, but may constitute a relatively large fraction of the plasma membrane. While rafts have a distinctive protein and lipid composition, all rafts do not appear to be identical in terms of either the proteins or the lipids that they contain. A variety of proteins, especially those involved in cell signaling, have been shown to partition into lipid rafts. As a result, lipid rafts are thought to be involved in the regulation of signal transduction. Experimental evidence suggests that there are probably several different mechanisms through which rafts control cell signaling. For example, rafts may contain incomplete signaling pathways that are activated when a receptor or other required molecule is recruited into the raft. Rafts may also be important in limiting signaling, either by physical sequestration of signaling components to block nonspecific interactions, or by suppressing the intrinsic activity of signaling proteins present within rafts.
This review provides an overview of the physical characteristics of lipid rafts and summarizes studies that have helped to elucidate the role of lipid rafts in signaling via receptor tyrosine kinases and G protein-coupled receptors.

3.449 Role of nephrin in proteinuric renal diseases

3.450 Transport of plasma membrane-derived cholesterol and the function of Niemann-Pick C1 protein
Wiegand, V., Chang, T-Y., StraussIII, J.F., Fahrenholz, F. and Gimpl, G.
FASEB J., ***17(6)***, *782-784 (2003)*

To visualize the intracellular transport of plasma membrane-derived cholesterol under physiological and pathophysiological conditions, a novel fluorescent cholesterol analog, 6-dansyl cholestanol (DChol), has been synthesized. We present several lines of evidence that DChol mimics cholesterol. The cholesterol probe could be efficiently incorporated into the plasma membrane via cyclodextrin-donor complexes. The itinerary of DChol from the plasma membrane to the cell was studied to determine its dependence on the function of Niemann-Pick C1 (NPC) protein. In all cells, DChol moved from the plasma membrane to the endoplasmic reticulum. Its further transport to the Golgi complex was observed but with marked differences among various cell lines. DChol was finally transported to small (~0.5 μm diameter) lipid droplets, a process that required functional acyl-CoA:cholesterol acyltransferase. In human NPC fibroblasts, NPC-like cells, or in cells mimicking the NPC phenotype, DChol was found in enlarged (>1 μm diameter) droplets. When the NPC-phenotype was corrected by transfection with NPC1, DChol was again found in small-sized droplets. Our data show that NPC1 has an essential role in the distribution of plasma membrane-derived cholesterol by maintaining the small size of cholesterol-containing lipid droplets in the cell.

3.451 Insights into the Association of Fc‘RII and TCR with Detergent-Resistant Membrane Domains: Isolation of the Domains in Detergent-Free Density Gradients Facilitates Membrane Fragment Reconstitution
Korzeniowaski, M., Kwiatkowska, K. and Sobota, A.
Biochemistry, ***42***, *5358-5367 (2003)*

Plasma membrane rafts are routinely isolated as detergent-resistant membranes (DRMs) floating in detergent-free density gradients. Here we show that both the presence and exclusion of TX-100 during the density gradient fractionation have profound effects on the location of Fc‘RII and TCR in DRM fractions. The presence of TX-100 during fractionation promoted solubilization of non-cross-linked Fc‘RII when the receptor was insufficiently dissolved upon cell lysis. In the detergent-supplemented gradients, TX-100 micelles floated, further enhancing dissociation of Fc‘RII and TCR from DRMs and promoting a shift of the receptors toward higher-density fractions. Hence, fractionation of cell lysates over the detergent-containing gradients enables isolation of DRMs devoid of weakly associated proteins, like nonactivated Fc ‘RII and TCR. On the other hand, in a detergent-free gradient, non-cross-linked Fc‘RII, fully soluble in 0.2% TX-100, was recovered in DRM fractions. Moreover, employment of the TX-100-free gradient for refractionation of intermediate-density fractions, derived from detergent-supplemented gradients and containing Fc‘RII and TCR, resulted in flotation of the receptors to buoyant fractions. An analysis of the

TX-100 concentration revealed that after fractionation of 0.2% TX-100 cell lysates in the absence of detergent, the level of TX-100 in DRM fractions was reduced to 0.01%, below the critical micelle concentration. Therefore, fractionation of detergent cell lysates over detergent-free gradients can mimic conditions for a membrane reconstitution, evoking association of a distinct subset of membrane proteins, including FcγRII and TCR, with DRMs.

3.452 Engineering of technetium-99m-binding artificial receptors for imaging gene expression
Simonova, M., Shtanko, O., Serrgeyev, N., Weissleder, R. and Bogdanov Jr, A.
*J. Gene Med., **5(12)**, 1956-1066 (2003)*

Background
Optimization of gene therapy protocols requires accurate and non-invasive quantification of vector delivery and gene expression. To facilitate non-invasive imaging of gene expression, we have genetically engineered 'artificial receptors', i.e. membrane proteins that bind 99mTc-oxotechnetate (99mTcOT) via transchelation from a complex with glucoheptonate. The latter is a component of a widely used clinical imaging kit.
Methods
The engineered marker proteins were designed as type I and II membrane proteins and consisted of (1) an 99mTcOT-binding domain, metallothionein (MT), and (2) a membrane-anchoring domain. Engineered constructs were used for transfection of COS-1 and 293 cells; the expression of mRNA was verified by RT-PCR.
Results
Immunofluorescent analysis, cell fractionation and immunoblotting revealed expression of marker proteins on plasma membrane. Transfection of cells resulted in strong positive staining of plasma membrane with anti-His-tag antibodies. Scintigraphic imaging in vitro confirmed the ability of transfected cells to bind 99mTcOT. The fraction of bound radioactivity reached a peak (3.53%) when 0.93 MBq 99mTcOT was added to transfected COS-1 cells. The experiment-to-control signal ratio was equal to 32 at the same added dose.
Conclusions
(1) Both types of engineered 'artificial receptors' were expressed on the surface of eukaryotic cells; (2) marker proteins were functional in binding 99mTcOT; and (3) type II membrane proteins were more efficient in binding 99mTcOT than type I proteins. We anticipate that the developed approach could be useful for 'tagging' transfected cells with 99mTcOT enabling imaging of tracking in vivo transduced cells or cell therapies.

3.453 p53 is present in synapses where it mediates mitochondrial dysfunction and synaptic degeneration in response to DNA damage, and oxidative and excitotoxic insults
Gilman, C.P., Chan, S.L., Guo, Z., Zhu, X., Greig, N. and mattson, M:P.
*NeuroMol. Med., **3(3)**, 159-172 (2003)*

A form of programmed cell-death called apoptosis occurs in neurons during development of the nervous system, and may also occur in a variety of neuropathological conditions. Here we present evidence obtained in studies of adult mice and neuronal cell cultures showing that p53 protein is present in synapses where its level and amount of phosphorylation are increased following exposure of the cells to the DNA-damaging agent etoposide. We also show that levels of active p53 increase in isolated cortical synaptosomes exposed to oxidative and excitotoxic insults. Increased levels of p53 also precede loss of synapsin I immunoreactive terminals in cultured hippocampal neurons exposed to etoposide. Synaptosomes from p53-deficient mice exhibit increased resistance to oxidative and excitotoxic insults as indicated by stabilization of mitochondrial membrane potential and decreased production of reactive oxygen species. Finally, we show that a synthetic inhibitor of p53 (PFT-α) protects synaptosomes from wild-type mice against oxidative and excitotoxic injuries, and preserves presynaptic terminals in cultured hippocampal neurons exposed to etoposide. Collectively, these findings provide the first evidence for a local transcription-independent action of p53 in synapses, and suggest that such a local action of p53 may contribute to the dysfunction and degeneration of synapses that occurs in various neurodegenerative disorders.

3.454 Latent infection membrane protein transmembrane FWLY is critical for intermolecular interaction, raft localization, and signaling
Yasui, T., Luftig, M., Soni, V. and Kieff, E.
*PNAS, **101(1)**, 278-283 (2004)*

Relatively little is known about the biochemical mechanisms through which the Epstein-Barr virus latent infection integral membrane protein 1 (LMP1) transmembrane domains cause constitutive LMP1 aggregation and continuous cytoplasmic C terminus-mediated signal transduction. We now evaluate the role of the three consecutive LMP1 hydrophobic transmembrane pairs, transmembrane domains (TM)1-2, TM3-4, and TM5-6, in intermolecular aggregation and NF-κB activation. LMP1TM1-2 enabled ≈40% of wild-type LMP1 cytoplasmic domain-mediated NF-κB activation, whereas TM3-4 or TM5-6 assayed in parallel had almost no effect independent of LMP1TM1-2. Alanine mutagenesis of conserved residues in LMP1TM1-2 identified $FWLY_{38-41}$ to be critical for LMP1TM1-2 intermolecular association with LMP1TM3-6. Further, in contrast to wild-type LMP1, LMP1 with $FWLY_{38-41}$ mutated to $AALA_{38-41}$ did not (*i*) significantly partition to lipid Rafts or Barges and effectively intermolecularly associate, (*ii*) enable cytoplasmic C terminus engagement of tumor necrosis factor receptor-associated factor 3, (*iii*) activate NF-κB, and thereby (*iv*) induce tumor necrosis factor receptor-associated factor 1 expression. Other LMP1 intermolecular associations were observed that involved LMP1TM1-2/LMP1TM1-2 or LMP1TM3-4/LMP1TM3-6 interactions; these probably also contribute to LMP1 aggregation. Because $FWLY_{38-41}$ was essential for LMP1-mediated signal transduction, and LMP1 activation of NF-κB is essential for proliferating B lymphocyte survival, inhibition of $LMP1FWLY_{41}$-mediated LMP1/LMP1 intermolecular interactions is an attractive therapeutic target.

3.455 Distinct subcellular localizations of Nox1 and Nox4 in vascular smooth muscle cells
Hilenski, L.L., Clempus, R.E., Quinn, M.T., Lambeth, J.D. and Griendling, K.K.
Arterioscler. Thromb. Vasc. Biol., ***24***, *1-8 (2004)*

Objective--Reactive oxygen species (ROS) that act as signaling molecules in vascular smooth muscle cells (VSMC) and contribute to growth, hypertrophy, and migration in atherogenesis are produced by multi-subunit NAD(P)H oxidases. Nox1 and Nox4, two homologues to the phagocytic NAD(P)H subunit $gp91^{phox}$, both generate ROS in VSMC but differ in their response to growth factors. We hypothesize that the opposing functions of Nox1 and Nox4 are reflected in their differential subcellular locations.
Methods and Results--We used immunofluorescence to visualize the NAD(P)H subunits Nox1, Nox4, and $p22^{phox}$ in cultured rat and human VSMC. Optical sectioning using confocal microscopy showed that Nox1 is co-localized with caveolin in punctate patches on the surface and along the cellular margins, whereas Nox4 is co-localized with vinculin in focal adhesions. These immunocytochemical distributions are supported by membrane fractionation experiments. Interestingly, $p22^{phox}$, a membrane subunit that interacts with the Nox proteins, is found in surface labeling and in focal adhesions in patterns similar to Nox1 and Nox4, respectively.
Conclusions--The differential roles of Nox1 and Nox4 in VSMC may be correlated with their differential compartmentalization in specific signaling domains in the membrane and focal adhesions.

3.456 Akt2, phosphatidylinositol 3-kinase, and PTEN are in lipid rafts of intestinal cells: role in absorption and differentiation
Li, X., et al
Gastroenterology, ***126***, *122-135 (2004)*

Background & Aims: In intestinal Na absorptive cells, phosphatidylinositol 3-kinase (PI 3-K) is involved in rapid epidermal growth factor (EGF) stimulation of Na absorption by the brush border membrane (BBM) Na^+/H^+ exchanger NHE3. However, how NHE3 is regulated by the PI 3-K pathway and the role of Akt2 are poorly defined. *Methods:* The localization of Akt, PI 3-K, and NHE3 was determined by either immunocytochemistry and/or membrane fractionation using OptiPrep density gradient centrifugation. *Results:* In ileum, active total Akt was present most in the villi and basal layer of the crypts, and Akt2 was mostly in villi. In villus cells, PI 3-K and Akt2 were mostly at the apical surface at which they were present partially in lipid rafts (LR). EGF increased PI 3-K and active Akt2 in ileal BBM at the same time that it increased PI 3-K-dependent trafficking of NHE3 to BBM and stimulation of Na absorption. However, Akt2 was only active in the detergent soluble (DS) pool and not LR of ileal BBM, which correlated with the presence of PTEN in LR. In Caco-2 cells, while EGF stimulated BB NHE3, Akt2 was active in both LR and DS pools. This correlated with the lack of PTEN in the LR of Caco-2 membranes. Akt2 also correlated with epithelial cell differentiation. Akt2 amount and activity were greater in differentiated than undifferentiated Caco-2 cells. *Conclusions:* These results suggest that LR may play an important role in determining the function of PI 3-K/Akt2 signaling, including stimulation of intestinal Na absorption. These results also suggest that LR-associated Akt2 may be involved in enterocyte differentiation.

3.457 Mutant presenilin (A260V) affects Rab8 in PC12D cell

Kametani, F., Usami, M., Tanaka, K., Kume, H. And Mori, H.
*Neurochem. Int., **44**, 313-320 (2004)*

Most familial early-onset Alzheimer's disease (FAD) is caused by mutations in the presenilin-1 (PS1) gene. Aβ is derived from amyloid precursor protein (APP) and an increased concentration of Aβ 42 is widely believed to be a pathological hallmark of abnormal PS function. Therefore, the interaction between PS1 and APP is a central theme in attempts to clarify the molecular mechanism of AD. To examine the effect of PS1 mutations on APP metabolism, we made PC12D cell lines that express human PS1 or mutant PS1 (A260V). In PC12D cells expressing the PS1A260V mutant, we found that Rab8, a GTPase involved in transport from the *trans*-Golgi network (TGN) to the plasma membrane (PM), was significantly reduced in PC12D cells expressing the A260V mutant and that APP C-terminal fragment (CTF), the direct precursor of Aβ, accumulated in the heavy membrane fraction including membrane vesicles involved in TGN-to-PM transport. Furthermore, the total intracellular Aβ production was reduced in these cells. Combined together, we have observed that PS1 mutation disturbs membrane vesicle transport, resulting in prolonged residence of APP CTF during TGN-to-PM transport pathway. Therefore, it is highly likely that reduction of Aβ is closely related to the retention of APP CTF during TGN-to-PM transport.

3.458 BACE1 suppression by RNA interferences in primary cortical neurons

Kao, S-C., Krichevsky, A.M., Kosik, K.S. and Tsai, L-H.
*J. Biol. Chem., **279(3)**, 1942-1949 (2004)*

Extracellular deposition of amyloid-β (Aβ) aggregates in the brain represents one of the histopathological hallmarks of Alzheimer's disease (AD). Aβ peptides are generated from proteolysis of the amyloid precursor proteins (APPs) by β- and γ-secretases. β-Secretase (BACE1) is a type I integral membrane glycoprotein that can cleave APP first to generate C-terminal 99- or 89-amino acid membrane-bound fragments containing the N terminus of Aβ peptides (βCTF). As BACE1 cleavage is an essential step for Aβ generation, it is proposed as a key therapeutic target for treating AD. In this study, we show that small interfering RNA (siRNA) specifically targeted to BACE1 can suppress BACE1 (but not BACE2) protein expression in different cell systems. Furthermore, BACE1 siRNA reduced APP βCTF and Aβ production in primary cortical neurons derived from both wild-type and transgenic mice harboring the Swedish APP mutant. The subcellular distribution of APP and presenilin-1 did not appear to differ in BACE1 suppressed cells. Importantly, pretreating neurons with BACE1 siRNA reduced the neurotoxicity induced by H_2O_2 oxidative stress. Our results indicate that BACE1 siRNA specifically impacts on β-cleavage of APP and may be a potential therapeutic approach for treating AD.

3.459 Incorporation of heterologous outer membrane and periplasmic proteins into *Escherichia coli* outer membrane vesicles

Kesty, N.C. and Kuehn, M.J.
*J. Biol. Chem., **279(3)**, 2069-2076 (2003)*

Gram-negative bacteria shed outer membrane vesicles composed of outer membrane and periplasmic components. Since vesicles from pathogenic bacteria contain virulence factors and have been shown to interact with eukaryotic cells, it has been proposed that vesicles behave as delivery vehicles. We wanted to determine whether heterologously expressed proteins would be incorporated into the membrane and lumen of vesicles and whether these altered vesicles would associate with host cells. Ail, an outer membrane adhesin/invasin from *Yersinia enterocolitica*, was detected in purified outer membrane and in vesicles from *Escherichia coli* strains DH5α, HB101, and MC4100 transformed with plasmid-encoded Ail. In vesicle-host cell co-incubation assays we found that vesicles containing Ail were internalized by eukaryotic cells, unlike vesicles without Ail. To determine whether lumenal vesicle contents could be modified and delivered to host cells, we used periplasmically expressed green fluorescent protein (GFP). GFP fused with the Tat signal sequence was secreted into the periplasm via the twin arginine transporter (Tat) in both the laboratory *E. coli* strain DH5α and the pathogenic enterotoxigenic *E. coli* ATCC strain 43886. Pronase-resistant fluorescence was detectable in vesicles from Tat-GFP-transformed strains, demonstrating that GFP was inside intact vesicles. Inclusion of GFP cargo increased vesicle density but did not result in morphological changes in vesicles. These studies are the first to demonstrate the incorporation of heterologously expressed outer membrane and periplasmic proteins into bacterial vesicles.

3.460 AHNAK interaction with the annexin 2/S100A10 complex regulates cell membrane cytoarchitecture
Benaud, C.B. et al
*J. Cell Biol., **164(1)**, 133-144 (2004)*

Remodelling of the plasma membrane cytoarchitecture is crucial for the regulation of epithelial cell adhesion and permeability. In Madin-Darby canine kidney cells, the protein AHNAK relocates from the cytosol to the cytosolic surface of the plasma membrane during the formation of cell–cell contacts and the development of epithelial polarity. This targeting is reversible and regulated by Ca^{2+}-dependent cell–cell adhesion. At the plasma membrane, AHNAK associates as a multimeric complex with actin and the annexin 2/S100A10 complex. The S100A10 subunit serves to mediate the interaction between annexin 2 and the COOH-terminal regulatory domain of AHNAK. Down-regulation of both annexin 2 and S100A10 using an annexin 2–specific small interfering RNA inhibits the association of AHNAK with plasma membrane. In Madin-Darby canine kidney cells, down-regulation of AHNAK using AHNAK-specific small interfering RNA prevents cortical actin cytoskeleton reorganization required to support cell height. We propose that the interaction of AHNAK with the annexin 2/S100A10 regulates cortical actin cytoskeleton organization and cell membrane cytoarchitecture.

3.461 Mechanism of recruiting Sec6/8 (exocyst) complex to the apical juntional complex during polarization of epithelial cells
Yeaman, C., Grindstaff, K.K. and Nelson, W.J.
*J. Cell Sci., **117**, 559-570 (2004)*

Sec6/8 (exocyst) complex regulates vesicle delivery and polarized membrane growth in a variety of cells, but mechanisms regulating Sec6/8 localization are unknown. In epithelial cells, Sec6/8 complex is recruited to cell-cell contacts with a mixture of junctional proteins, but then sorts out to the apex of the lateral membrane with components of tight junction and nectin complexes. Sec6/8 complex fractionates in a high molecular mass complex with tight junction proteins and a portion of E-cadherin, and co-immunoprecipitates with cell surface-labeled E-cadherin and nectin-2α. Recruitment of Sec6/8 complex to cell-cell contacts can be achieved in fibroblasts when E-cadherin and nectin-2α are co-expressed. These results support a model in which localized recruitment of Sec6/8 complex to the plasma membrane by specific cell-cell adhesion complexes defines a site for vesicle delivery and polarized membrane growth during development of epithelial cell polarity.

3.462 Contrasting functions of calreticulin and calnexin in glycoprotein folding and ER quality control
Molinari, M. et al
*Mol. Cell, **13,** 125-135 (2004**)***

Calreticulin and calnexin are homologous lectins that serve as molecular chaperones for glycoproteins in the endoplasmic reticulum of eukaryotic cells. Here we show that calreticulin depletion specifically accelerates the maturation of cellular and viral glycoproteins with a modest decrease in folding efficiency. Calnexin depletion prevents proper maturation of some proteins such as influenza hemagglutinin but does not interfere appreciably with the maturation of several others. A dramatic loss of stringency in the ER quality control with transport at the cell surface of misfolded glycoprotein conformers is only observed when substrate access to both calreticulin and calnexin is prevented. Although not fully interchangeable during assistance of glycoprotein folding, calreticulin and calnexin may work, independently, as efficient and crucial factors for retention in the ER of nonnative polypeptides.

3.463 Smooth muscle raft-like membranes
Baron, C.B. and Coburn, R.F.
*J. Lipid Res.,**45**, 41-53 (2004)*

We developed a method for extracting raft-like, liquid-ordered membranes from the particulate fraction prepared from porcine trachealis smooth muscle. This fraction, which contains most of the plasma membrane in this tissue, was homogenized in the presence of cold 0.5% Triton X-100. After centrifugation, membranes containing high contents of sphingomyelin (SM) and cholesterol and low phosphatidylcholine (PC) contents remained in the pellet. Thirty-five millimolar octyl glucoside (OG) extracted 75% of these membranes from the Triton X-100-resistant pellet. These membranes had low buoyant densities and accounted for 28% of the particulate fraction lipid. Their lipid composition, 22% SM, 60% cholesterol,

11% phosphatidylethanolamine, 8% PC, <1% phosphatidylinositol, and coisolation with 5'-nucleotidase and caveolin-1 suggest that they are liquid-ordered membranes. We compared characteristics of OG and Triton X-100 extractions of the particulate fraction. In contrast to Triton X-100 extractions, membranes released from the particulate fraction by OG were mainly collected in low buoyant fractions at densities ranging from 1.05 to 1.11 g/ml and had phospholipid and cholesterol contents consistent with a mixture of liquid-ordered and liquid-disordered membranes.

3.464 The EF-hand Ca^{2+}-binding protein p22 plays a role in microtubule and endoplasmic reticulum organization and dynamics with distinct Ca^{2+}-binding requirements
Andrade, j., Zhao, H., Titus, B., Pearce, T. and Barroso, M.
*Mol. Biol. Cell, **15**, 481-496 (2004)*

We have reported that p22, an *N*-myristoylated EF-hand Ca^{2+}-binding protein, associates with microtubules and plays a role in membrane trafficking. Here, we show that p22 also associates with membranes of the early secretory pathway membranes, in particular endoplasmic reticulum (ER). On binding of Ca^{2+}, p22's ability to associate with membranes increases in an *N*-myristoylation-dependent manner, which is suggestive of a nonclassical Ca^{2+}-myristoyl switch mechanism. To address the intracellular functions of p22, a digitonin-based "bulk microinjection" assay was developed to load cells with anti-p22, wild-type, or mutant p22 proteins. Antibodies against a p22 peptide induce microtubule depolymerization and ER fragmentation; this antibody-mediated effect is overcome by preincubation with the respective p22 peptide. In contrast, *N*-myristoylated p22 induces the formation of microtubule bundles, the accumulation of ER structures along the bundles as well as an increase in ER network formation. An *N*-myristoylated Ca^{2+}-binding p22 mutant, which is unable to undergo Ca^{2+}-mediated conformational changes, induces microtubule bundling and accumulation of ER structures along the bundles but does not increase ER network formation. Together, these data strongly suggest that p22 modulates the organization and dynamics of microtubule cytoskeleton in a Ca^{2+}-independent manner and affects ER network assembly in a Ca^{2+}-dependent manner.

3.465 Ligand-independent redistribution of Fas (CD95) into lipid rafts mediates clonotypic T cell death
Muppidi, J. and Siegel, R.M.
*Nature Immunol., **5(2)**, 182-189 (2004)*

Clonotypic elimination of activated T cells through Fas–Fas ligand (CD95–CD95L) interactions is one mechanism of peripheral self-tolerance. T cell receptor (TCR) stimuli trigger FasL synthesis but also sensitize activated T cells to Fas-mediated apoptosis through an unknown mechanism. Here we show that TCR restimulation of activated human $CD4^+$ T cells resulted in Fas translocation into lipid raft microdomains before binding FasL, rendering these cells sensitive to apoptosis after stimulation with bivalent antibody or FasL. Disruption of lipid rafts reduced sensitivity to Fas-mediated apoptosis after TCR restimulation. Thus, the redistribution of Fas and other tumor necrosis factor family receptors into and out of lipid rafts may dynamically regulate the efficiency and outcomes of signaling by these receptors.

3.466 A novel fluorescence resonance energy transfer assay demonstrates that the human immunodeficiency virus type I $Pr55^{Gag}$ I domain mediates Gag-Gag interactions
Derdowski, A., Ding, L. and Spearman, P.
*J.Virol., **78(3)**, 1230-1242 (2004)*

Human immunodeficiency virus type 1 (HIV-1) assembly takes place at the plasma membrane of cells and is directed by the $Pr55^{Gag}$ polyprotein (Gag). One of the essential steps in the assembly process is the multimerization of Gag. We have developed a novel fluorescence resonance energy transfer (FRET) assay for the detection of protein-protein interactions between Gag molecules. We demonstrate that Gag multimerization takes place primarily on cellular membranes, with the majority of these interactions occurring on the plasma membrane. However, distinct sites of Gag-Gag interaction are also present at punctate intracellular locations. The I domain is a functional assembly domain within the nucleocapsid region of Gag that affects particle density, the subcellular localization of Gag, and the formation of detergent-resistant Gag protein complexes. Results from this study provide evidence that the I domain mediates Gag-Gag interactions. Using Gag-fluorescent protein fusion constructs that were previously shown to define the minimal I domain within HIV-1 $Pr55^{Gag}$, we show by FRET techniques that protein-protein interactions are greatly diminished when Gag proteins lacking the I domain are expressed. Gag-Tsg101 interactions are also seen in living cells and result in a shift of Tsg101 to the plasma membrane. The results within this study provide direct evidence that the I domain mediates protein-protein interactions

between Gag molecules. Furthermore, this study establishes FRET as a powerful tool for the detection of protein-protein interactions involved in retrovirus assembly.

3.467 The K1 protein of Kaposi's sarcoma-associated herpesvirus activates the Akt signaling pathway
Tomlinson, C.C. and Damania, B.
J. Virol., ***78(4)****, 1918-1927 (2004)*

Kaposi's sarcoma-associated herpesvirus (KSHV) has been implicated in Kaposi's sarcoma, as well as in primary effusion lymphoma and multicentric Castleman's disease. The K1 protein of KSHV has been shown to induce cellular transformation and focus formation and to deregulate B-lymphocyte signaling pathways by functionally mimicking the activated B-cell receptor complex. Here we show that expression of K1 in B lymphocytes targets the phosphatidylinositol-3 kinase pathway, leading to the activation of the Akt kinase and the inhibition of the phosphatase PTEN. We also demonstrate that activation of Akt by the K1 protein leads to the phosphorylation and inhibition of members of the forkhead (FKHR) transcription factor family, which are key regulators of cell cycle progression and apoptosis. We demonstrate that K1 can inhibit apoptosis induced by the FKHR proteins and by stimulation of the Fas receptor. Our observations suggest that the K1 viral protein promotes cell survival pathways and may contribute to KSHV pathogenesis by preventing virally infected cells from undergoing apoptosis prematurely.

3.468 Rap1 up-regulation and activation on plasma membrane regulates T cell adhesion
Bivona, T.G. et al
J. Cell Biol., ***164(3)****, 461-470 (2004)*

Rap1 and Ras are closely related GTPases that share some effectors but have distinct functions. We studied the subcellular localization of Rap1 and its sites of activation in living cells. Both GFP-tagged Rap1 and endogenous Rap1 were localized to the plasma membrane (PM) and endosomes. The PM association of GFP-Rap1 was dependent on GTP binding, and GFP-Rap1 was rapidly up-regulated on this compartment in response to mitogens, a process blocked by inhibitors of endosome recycling. A novel fluorescent probe for GTP-bound Rap1 revealed that this GTPase was transiently activated only on the PM of both fibroblasts and T cells. Activation on the PM was blocked by inhibitors of endosome recycling. Moreover, inhibition of endosome recycling blocked the ability of Rap1 to promote integrin-mediated adhesion of T cells. Thus, unlike Ras, the membrane localizations of Rap1 are dynamically regulated, and the PM is the principle platform from which Rap1 signaling emanates. These observations may explain some of the biological differences between these GTPases.

3.469 The Arf activator Gea2p and P-type ATPase Drs2p interact at the Golgi in *Saccharomyces cerevisiae*
Chantalai, S.C. et al
J. Cell Sci., ***117****, 711-722 (2004)*

Arf GTPases regulate both the morphological and protein sorting events that are essential for membrane trafficking. Guanine nucleotide exchange factors (GEFs) specific for Arf proteins determine when and where Arf GTPases will be activated in cells. The yeast Gea2p Arf GEF is a member of an evolutionarily conserved family of high molecular mass Arf GEFs that are peripherally associated with membranes. Nothing is known about how these proteins are localized to membranes, and few direct binding partners have been identified. In yeast, Gea2p has been implicated in trafficking through the Golgi apparatus and in maintaining Golgi structure. A major function of the Golgi apparatus is the packaging of cargo into secretory granules or vesicles. This process occurs through a series of membrane transformation events starting with fenestration of a saccular membrane, and subsequent remodeling of the fenestrated membrane into a mesh-like tubular network. Concentration of secretory cargo into nodes of the tubular network leads to enlargement of the nodes, which correspond to forming vesicles/granules, and thinning of the surrounding tubules. The tubules eventually break to release the secretory vesicles/granules into the cytoplasm. This process is highly conserved at the morphological level from yeast to mammalian cells. Drs2p, a multi-span transmembrane domain protein and putative aminophospholipid translocase, is required for the formation of a class of secretory granules/vesicles in yeast. Here we show that Drs2p interacts directly with Gea2p, both in vitro and in vivo. We mapped the domain of interaction of Drs2p to a 20-amino-acid region of the C-terminal cytoplasmic tail of the protein, adjacent to a region essential for Drs2p function. Mutations in Gea2p that abolish interaction with Drs2p are clustered in the C-terminal

third of the Sec7 domain, and are important for Gea2p function. We characterize one such mutant that has a thermosensitive phenotype, and show that it has morphological defects along the secretory pathway in the formation of secretory granules/vesicles.

3.470 **The matrix protein of Marburg virus is transported to the plasma membrane along cellular membranes: exploiting the retrograde late endosomal pathway**
Kolesnikova, L., Bamberg, S., Berghöfer, B. and Becker, S.
J. Virol., ***78(5)***, *2382-2393 (2004)*

VP40, the matrix protein of Marburg virus, is a peripheral membrane protein that has been shown to associate with membranes of multivesicular bodies (MVBs) (L. Kolesnikova, H. Bugany, H.-D. Klenk, and S. Becker, J. Virol. **76:**1825-1838, 2002). The present study revealed that VP40 is bound to cellular membranes rapidly after synthesis. Time course studies were performed to trace the distribution of VP40 during the course of expression. First, VP40 was homogenously distributed throughout the cytoplasm, although the majority of protein (70%) was already membrane associated. Next, VP40 accumulated in MVBs and in tubular protrusions emerging from MVBs. Finally, VP40 appeared in a patch-like pattern beneath the plasma membrane. These morphological results were supported by **iodixanol** density gradient analyses. The majority of VP40-positive membranes were first detected comigrating with small vesicles. VP40 was then shifted to fractions containing endosomal marker proteins, and later, to fractions containing plasma membrane marker proteins. Blocking of protein synthesis by use of cycloheximide at the time when VP40 was mainly associated with the small vesicles did not prevent the redistribution of VP40 to the late endosomes and further to the plasma membrane. The inhibition of intracellular vesicular trafficking by monensin significantly reduced the appearance of VP40 at the plasma membrane. In conclusion, we suggest that the transport of the Marburg virus matrix protein VP40 involves its accumulation in MVBs followed by the redistribution of VP40-enriched membrane clusters to the plasma membrane.

3.471 **Bicarbonate-responsive “soluble” adenylyl cyclase defines a nuclear camp microdomain**
Zippin, J.H. et al
J. Cell Biol., ***164(4)***, *527-534 (2004)*

Bicarbonate-responsive "soluble" adenylyl cyclase resides, in part, inside the mammalian cell nucleus where it stimulates the activity of nuclear protein kinase A to phosphorylate the cAMP response element binding protein (CREB). The existence of this complete and functional, nuclear-localized cAMP pathway establishes that cAMP signals in intracellular microdomains and identifies an alternate pathway leading to CREB activation.

3.472 **Site of docking and fusion of insulin secretory granules in live MIN6 β cells analyzed by TAT-conjugated anti-syntaxin 1 antibody and total internal reflection fluorescence microscopy**
Ohara-Imaizumi, M. et al
J. Biol. Chem., ***279(9)***, *8403-8408 (2004)*

To determine the site of insulin exocytosis in the pancreatic βcell plasma membrane, we analyzed the interaction between the docking/fusion of green fluorescent protein-tagged insulin granules and syntaxin 1 labeled by TAT-conjugated Cy3-labeled antibody (Ab) using total internal reflection fluorescence microscopy (TIRFM). Monoclonal Ab against syntaxin 1 was labeled with Cy3 then conjugated with the protein transduction domain of HIV-1 TAT. TAT-conjugated Cy3-labeled anti-syntaxin 1 Ab was transduced rapidly into the subplasmalemmal region in live MIN6 βcells, which enabled us to observe the spatial organization and distribution of endogenous syntaxin 1. TIRFM imaging revealed that syntaxin 1 is distributed in numerous separate clusters in the intact plasma membrane, where insulin secretory granules were docked preferentially to the sites of syntaxin 1 clusters, colocalizing with synaptosomal-associated protein of 25 kDa (SNAP-25) clusters. TIRFM imaging analysis of the motion of single insulin granules demonstrated that the fusion of insulin secretory granules stimulated by 50 mM KCl occurred exclusively at the sites of the syntaxin 1 clusters. Cholesterol depletion by methyl-β-cyclodextrin treatment, in which the syntaxin 1 clusters were disintegrated, decreased the number of docked insulin granules, and, eventually the number of fusion events was significantly reduced. Our results indicate that 1) insulin exocytosis occurs at the site of syntaxin 1 clusters; 2) syntaxin 1 clusters are essential for the docking and fusion of insulin granules in MIN6 βcells; and 3) the sites of syntaxin 1 clusters are distinct from flotillin-1 lipid rafts.

3.473 Sphingolipid-cholesterol domains (lipid rafts) in normal human and dog thyroid follicular cells are not involved in thyrotropin receptor signaling
Costa, M.J. et al
*Endocrinology, **145(3)**, 1464-1472 (2004)*

Partition of signaling molecules in sphingolipid-cholesterol-enriched membrane domains, among which are the caveolae, may contribute to signal transduction efficiency. In normal thyroid, nothing is known about a putative TSH/cAMP cascade compartmentation in caveolae or other sphingolipid-cholesterol-enriched membrane domains. In this study we show for the first time that caveolae are present in the apical membrane of dog and human thyrocytes: caveolin-1 mRNA presence is demonstrated by Northern blotting in primary cultures and that of the caveolin-1 protein by immunohistochemistry performed on human thyroid tissue. The TSH receptor located in the basal membrane can therefore not be located in caveolae. We demonstrate for the first time by biochemical methods the existence of sphingolipid-cholesterol-enriched domains in human and dog thyroid follicular cells that contain caveolin, flotillin-2, and the insulin receptor. We assessed a possible sphingolipid-cholesterol-enriched domains compartmentation of the TSH receptor and the α- subunit of the heterotrimeric G_s and G_q proteins using two approaches: Western blotting on detergent-resistant membranes isolated from thyrocytes in primary cultures and the influence of 10 mM methyl-ß-cyclodextrin, a cholesterol chelator, on basal and stimulated cAMP accumulation in intact thyrocytes. The results from both types of experiments strongly suggest that the TSH/cAMP cascade in thyroid cells is not associated with sphingolipid-cholesterol-enriched membrane domains.

3.474 Characterization of the Lassa virus matrix protein Z: electron microscopic study of virus-like particles and interaction with the nucleoprotein (NP)
Eichler, R. et al
*Virus Res., **100**, 249-255 (2004)*

Lassa virus is the causative agent of a hemorrhagic fever endemic in west Africa. The RNA genome of Lassa virus encodes the glycoprotein precursor GP-C, a nucleoprotein (NP), the viral polymerase L and a small protein Z (11 kDa). Here, we analyze the role of Z protein for virus maturation. We have recently shown that expression of Z protein in the absence of other viral proteins is sufficient for the release of enveloped Z-containing particles. In this study, we examined particles secreted into the supernatant of a stably Z protein-expressing CHO cell line by electron microscopy. The observed Z-induced virus-like particles did not significantly differ in their morphology and size from Lassa virus particles. Mutation of two proline-rich domains within Z which are known to drastically reduce the release of virus-like particles, had no effect on the cellular localization of the protein nor on its membrane-association. Furthermore, we present evidence that Z interacts with the NP. We assume that Z recruits NP to cellular membranes where virus assembly takes place. We conclude from our data that Lassa virus Z protein plays an essential role in Lassa virus maturation.

3.475 Glycosylphosphatidylinositol-anchored proteins and actin cytoskeleton modulate chloride transport by channels formed by the *Helicobacter pylori* vacuolating cytotoxin VacA in HeLa cells
Gauthier, N.C. et al
*J. Biol. Chem., **279(10)**, 9481-9489 (2004)*

The vacuolating cytotoxin VacA is an important virulence factor of *Helicobacter pylori*. Removing glycosylphosphatidylinositol-anchored proteins (GPI-Ps) from the cell surface by phosphatidylinositol-phospholipase C or disrupting the cell actin cytoskeleton by cytochalasin D reduced VacA-induced vacuolation of cells (Ricci V., Galmiche, A., Doye, A., Necchi, V., Solcia, E., and Boquet, P. (2000) *Mol. Biol. Cell* 11, 3897-3909). Using the fluorescent dye 6-methoxy-*N*-ethylquinolinium chloride, an indicator for cytosolic chloride, we have investigated the role of either GPI-Ps or actin cytoskeleton in the activity of the selective anionic channel formed by VacA at the plasma membrane level. Removal of GPI-Ps from HeLa cell surfaces did not impair VacA localization into lipid rafts but strongly reduced VacA channel-mediated cell influx and efflux of chloride. Disruption of the actin cytoskeleton of HeLa cells by cytochalasin D did not affect VacA localization in lipid rafts but blocked VacA cell internalization and inhibited cell vacuolation while increasing the overall chloride transport by the toxin channel at the cell

surface. Specific enlargement of Rab7-positive compartments induced by VacA could be mimicked by the weak base chloroquine alone, and the vacuolating activities of either chloroquine alone or VacA were blocked with the same potency by the anion channel blocker 5-nitro-2-(3-phenylpropylamino)-benzoic acid shown to inhibit VacA channel activity (Tombola, F., Oregna, F., Brutsche, S., Szabò, I., Del Giudice, G., Rappuoli, R., Montecucco, C., Papini, E., and Zoratti, M. (1999) *FEBS Lett.* 460, 221-225). We suggest that formation of functional VacA channels at the cell surface required GPI-Ps and that endocytosis of these channels by an actin-dependent process increases the chloride content of late endosomes that accumulate weak bases, provoking their enlargement by osmotic swelling.

3.476 Human immunodeficiency virus type 1 Nef activates p21-activated kinase vis recruitment into lipid rafts

Krautkrämer, E., Giese, S.I., Gasteier, J.E., Muuranyi, W. and Fackler, O.T.
*J. Virol., **78(8)**, 4085-4097 (2004)*

The Nef protein of human immunodeficiency virus type 1 is an important factor in AIDS pathogenesis. In addition to downregulating CD4 and major histocompatibility complex class I molecules from the cell surface, as well as increasing virion infectivity, Nef triggers activation of the T-cell receptor (TCR) cascade to facilitate virus spread. Signaling pathways that are induced by Nef have been identified; however, it is unclear how and in which subcellular compartment Nef triggers signaling. Nef recruits a multiprotein complex to activate the cellular Pak kinase that mediates downstream effector functions. Since a subpopulation of Nef is present in detergent-insoluble microdomains (lipid rafts) from where physiological TCR signaling is initiated, we tested whether lipid rafts are instrumental for Nef-mediated Pak activation. In flotation analysis, Nef-associated Pak activity exclusively fractionated with lipid rafts. Activation of Pak in the presence of Nef coincided with lipid raft recruitment of the kinase, which was otherwise excluded from detergent-insoluble microdomains. Experimental solubilization of lipid rafts interfered with the association of Pak activity with Nef. To analyze the importance of the raft localization for Nef function more rigorously, we generated a palmitoylated Nef (PalmNef). PalmNef was highly enriched in lipid rafts and associated with significantly higher levels of Pak activity than Nef. Notably, activation of Pak by its physiological activators, Cdc42 and Rac, also occurred in lipid rafts and required raft integrity. Together, these data suggest that Nef induces signal transduction via the recruitment of a signaling machinery including Pak into lipid rafts, thereby mimicking a physiological cellular mechanism to initiate the TCR cascade.

3.477 Conserved "PAL" sequence in presenilins is essential for γ-secretase activity, but not required for formation or stabilization of γ-secretase complexes

Wang, J., Brunkan, A.L., Hecimovic, S., Walker, E. and Goate, A.
*Neurobiol.of Disease, **15**, 654-666 (2004)*

Generation of Aβ from the β-amyloid precursor protein (APP) requires a series of proteolytic processes, including an intramembranous cleavage catalyzed by an aspartyl protease, γ-secretase. Two aspartates in presenilins (PS) are required for γ-secretase activity (D257 and D385 of PS1), suggesting that PS may be part of this protease. Little is known concerning the importance of other sequences in PS for activity. We introduced point mutations (P433L, A434D, L435R) into a completely conserved region C-terminal to transmembrane domain eight of PS1. The P433L mutation abolished PS1 endoproteolysis as well as γ-secretase cleavage of APP and Notch in PS1/2 K/O cells. In HEK cells, expression of PS1/P433L reduced Aβ production and caused accumulation of APP C-terminal stubs. When the P433L mutation was introduced into the non-cleavable Δexon 9 (ΔE9) variant of PS1, it abolished γ-secretase cleavage of APP and Notch. The P433L holoprotein is stable and incorporated into the high molecular weight γ-secretase complex, arguing that P433 is not necessary for formation or stabilization of the γ-secretase complex. Other non-conservative mutations in the invariant $P_{433}A_{434}L_{435}$ sequence also result in a phenotype that is indistinguishable from the aspartate mutants, suggesting a direct involvement of this sequence in γ-secretase activity.

3.478 Secreted MMP9 promotes angiogenesis more efficiently than constitutive active MMP9 bound to the tumor cell surface

Mira, E. et al
*J. Cell Sci., **117**, 1847-1856 (2004)*

Association of matrix metalloprotease 9 (MMP9) to the cell membrane is considered important in tumor growth and angiogenesis. To dissect this regulatory mechanism, we generated raft and non-raft MMP9 chimeras to force membrane expression in the MCF-7 human breast carcinoma cell line. MMP9 targeting to non-raft cell surface domains rendered a constitutive active membrane MMP9 form, suggesting a contribution by the lipid environment in MMP activation. We generated human breast cancer xenograft models using MCF-7 cells overexpressing secreted and membrane-anchored MMP9. The non-raft MMP9 chimera was constitutively active at the cell membrane in xenografts, but this activation did not correlate with an increase in MMP9-induced angiogenesis. Capillary number and vessel perimeter were specifically increased only in tumors overexpressing wild-type MMP9 (the secreted form); this increase was inhibited when tumors were induced in doxycycline-treated mice. Xenografts from tumor cells overexpressing wild-type MMP9 showed increased vascular endothelial growth factor (VEGF)/VEGFR2 receptor association, which was also dependent on MMP9 activity. These observations indicate that membrane location can influence MMP9 activity in vitro and in vivo, and confirm the relevance of stromal-associated, but not tumor-bound MMP9 in mediating tumor-induced angiogenesis.

3.479 Implication of ZW10 in membrane trafficking between the endoplasmic reticulum and Golgi
Hirose, H. et al
EMBO J., ***23***, *1267-1278 (2004)*

ZW10, a dynamitin-interacting protein associated with kinetochores, is known to participate directly in turning off of the spindle checkpoint. In the present study, we show that ZW10 is located in the endoplasmic reticulum as well as in the cytosol during interphase, and forms a subcomplex with RINT-1 (Rad50-interacting protein) and p31 in a large complex comprising syntaxin 18, an endoplasmic reticulum-localized t-SNARE implicated in membrane trafficking. Like conventional syntaxin-binding proteins, ZW10, RINT-1 and p31 dissociated from syntaxin 18 upon Mg^{2+}-ATP treatment in the presence of NSF and α-SNAP, whereas the subcomplex was not disassembled. Overexpression, microinjection and knockdown experiments revealed that ZW10 is involved in membrane trafficking between the endoplasmic reticulum and Golgi. The present results disclose an unexpected role for a spindle checkpoint protein, ZW10, during interphase.

3.480 Appropriate NR1-NR1 disulfide-linked homodimer formation is requisite for efficient expression of functional, cell surface N-methyl-D-aspartate NR1/NR2 receptors
Papadakis, M., Hawkins, L.M. and Stephenson, F.A.
J. Biol. Chem., ***279(15)***, *14703-14712 (2004)*

A c-Myc epitope-tagged *N*-methyl-D-aspartate receptor NR1-2a subunit was generated, NR1-$2a_{c\text{-}Myc}$, where the tag was inserted after amino acid 81. NR1-$2a_{c\text{-}Myc}$ /NR2A receptors when expressed in mammalian cells are not trafficked to the cell surface nor do they yield cell cytotoxicity post-transfection. NR1-$2a_{c\text{-}Myc}$ was, however, shown to assemble with NR2A subunits by immunoprecipitation and [^{3}H]MK801 radioligand binding assays. Immunoblots of cells co-transfected with wild-type NR1-2a/NR2A subunits yielded two NR1-2a immunoreactive species with molecular masses of 115 and 226 kDa. Two-dimensional electrophoresis under non-reducing and reducing conditions revealed that the 226-kDa band contained disulfide-linked NR1-2a subunits. Only the 115-kDa NR1-2a species was detected for NR1-$2a_{c\text{-}Myc}$/NR2A. The c-Myc epitope is inserted adjacent to cysteine 79 of the NR1-2a subunit; therefore, it is possible that the tag may prevent the formation of NR1 disulfide bridges. A series of cysteine →alanine NR1-2a mutants was generated, and the NR1-2a mutants were co-expressed with NR2A or NR2B subunits in mammalian cells and characterized with respect to cell surface expression, cell cytotoxicity post-transfection, co-association by immunoprecipitation, and immunoblotting following SDS-PAGE under both reducing and non-reducing conditions. When co-expressed with NR2A in mammalian cells, NR1-$2a_{C79A}$/NR2A displayed similar properties to NR1-$2a_{c\text{-}Myc}$/NR2A in that the 226-kDa NR1 immunoreactive species was not detectable, and trafficking to the cell surface was impaired compared with wild-type NR1/NR2 receptors. These results provide the first biochemical evidence for the formation of NR1-NR1 intersubunit disulfide-linked homodimers involving cysteine 79. They suggest that disulfide bridging and structural integrity within the NR1 N-terminal domain is requisite for cell surface *N*-methyl-D-aspartate receptor expression.

3.481 Gene and protein characterization of the human glutathione S-transferase kappa and evidence for a peroxisomal localization
Morel, F. et al
J. Biol. Chem., ***279(16)***, *16246-16253 (2004)*

Kappa class glutathione *S*-transferase (GST) cDNA sequences have been identified in rat, mouse, and human. In the present study, we determined the structure and chromosomal location of the human GST Kappa 1 (*hGSTK1*) gene, characterized the protein, and demonstrated its subcellular localization. The human gene spans ~5 kb, has 8 exons, and maps onto chromosome 7q34. The 5'-flanking region lacks TATA or CCAAT boxes, but there is an initiator element overlapping the transcription start site. hGSTK1 amino acid sequence showed homology to bacterial 2-hydroxychromene-2-carboxylate isomerase, an enzyme involved in naphthalene degradation pathway. hGSTK1 mRNA was expressed in all of the organs examined. Subcellular fractionation of HepG2 cells showed that the protein was located in peroxisomes and mitochondria and was not detectable in cytoplasm. The peroxisomal localization was confirmed by transfection of HepG2 cells with a plasmid coding a green fluorescent protein fused inframe to the N terminus of hGSTK1. The C terminus of hGSTK1 was essential for localization of the protein to peroxisomes, and the C-terminal sequence Ala-Arg-Leu represents a peroxisome targeting signal. This is the first time that a human GST has been found in peroxisomes, suggesting a new function for this family of enzymes.

3.482 Pen-2 is sequestered in the endoplamic reticulum and subjected to ubiquitylation and proteasome-mediated degradation in the absence of presenilin
Bergmann, A. et al
J. Biol. Chem., ***279(16)***, *16744-16753 (2004)*

The γ-secretase complex catalyzes intramembrane proteolysis of a number of transmembrane proteins, including amyloid precursor protein, Notch, ErbB4, and E-cadherin. γ-Secretase is known to contain four major protein constituents: presenilin (PS), nicastrin, Aph-1, and Pen-2, all of which are integral membrane proteins. There is increasing evidence that the formation of the complex and the stability of the individual components are tightly controlled in the cell, assuring correct composition of functional complexes. In this report, we investigate the topology, localization, and mechanism for destabilization of Pen-2 in relation to PS function. We show that PS1 regulates the subcellular localization of Pen-2: in the absence of PS, Pen-2 is sequestered in the endoplasmic reticulum (ER) and not transported to post-ER compartments, where the mature γ-secretase complexes reside. PS deficiency also leads to destabilization of Pen-2, which is alleviated by proteasome inhibitors. In keeping with this, we show that Pen-2, which adopts a hairpin structure with the N and C termini facing the luminal space, is ubiquitylated prior to degradation and presumably retrotranslocated from the ER to the cytoplasm. Collectively, our data suggest that failure to become incorporated into the γ-secretase complex leads to degradation of Pen-2 through the ER-associated degradation-proteasome pathway.

3.483 Seasonal varation in cytochrome P450 immunopositive protein levels, lipid peroxidation and genetic toxicity in digestive gland of the mussel *Mytilus edulis*
Shaw, J.P. et al
Aquatic Tox., ***67***, *325-336 (2004)*

The relationship between cytochrome P450 1A- and 2E-immunopositive proteins, lipid peroxidation and DNA strand breaks (SBs) was studied in *Mytilus edulis* digestive gland at different seasons and at different sites around the UK coast. Cytochrome P4501A (CYP1A)-immunopositive protein and DNA strand breaks were generally lowest in December but there was no correlation between PAH exposure (indicated by chemical measurement and CYP1A-immunopositive protein expression) and DNA strand breaks which was highest at the relatively non-polluted site (Port Quin). As with CYP1A, CYP2E1-immunopositive protein was maximal at most sites in May. Lipid peroxidation, in contrast, did not alter markedly throughout the year. In conclusion, DNA strand breakage was not correlated with any of the above parameters although it did correlate with "scope for growth" as did the inverse of PAH levels. The study highlights the need to establish the relative contribution of DNA damage and DNA repair processes to the production of DNA strand breaks and emphasises the need to consider seasonal variation in interpretation of biomarkers.

3.484 The 2003 ASBMB-Avanti Award in Lipids Address: applications of novel synthetic lipids to biological problems
Bittmann, R.
Chemistry & Lipids, ***129***, *111-131 (2004)*

This paper is an overview of the 2003 Avanti Award in Lipids address that was presented by Robert Bittman at the American Society for Biochemistry and Molecular Biology (ASBMB) Annual Meeting held in San Diego, CA in conjunction with meetings of five other FASEB Societies, April 15, 2003. The theme of the lecture is: "How can the chemical synthesis of unnatural lipids provide insights into problems ranging from cell biology to biophysics?" The following examples are presented: (1) novel ceramide analogs as experimental anticancer agents, (2) photoactivatable sphingosine 1-phosphate analogs as probes of protein targets of this bioactive lipid, (3) a ^{13}C-enriched cerebroside as a quantitative probe of glycosphingolipid (GSL) transbilayer distribution in bilayers with and without sphingomyelin, (4) *cis* and *trans* unsaturated sphingomyelin analogs as modulators of the existence of cholesterol-enriched microdomains (rafts) that may facilitate fusion of alphaviruses with target membranes, (5) ceramide as an indirect enhancer of the permeabilization of membranes induced by cholesterol-specific cytolysins, (6) fluorescent GSL analogs of widely disparate structure as probes of the molecular features responsible for the selective internalization of GSLs in caveolae of living mammalian cells, (7) enantiomeric lysophosphatidic acid (LPA) analogs as probes of receptor subtypes that mediate LPA signaling, and (8) phosphonocholine analogs of the antitumor ether lipid ET-18-OCH_3 as tools for discerning the primary targets that are critical for cytotoxic activity in tumor cells.

3.485 CD44 interaction with ankyrin and IP_3 receptor in lipid rafts promotes hyaluronan-mediated Ca^{2+} signaling to nitric oxide production and endothelial cell adhesion and proliferation

Singleton, P.A. and Bourguignon, L.Y.W.
Exp. Cell Res., ***295***, *102-118 (2004)*

In this study, we have showed that aortic endothelial cells (GM7372A cell line) express CD44v10 [a hyaluronan (HA) receptor], which is significantly enriched in cholesterol-containing lipid rafts (characterized as caveolin-rich plasma membrane microdomains). HA binding to CD44v10 promotes recruitment of the cytoskeletal protein, ankyrin and inositol 1,4,5-triphosphate (IP_3) receptor into cholesterol-containing lipid rafts. The ankyrin repeat domain (ARD) of ankyrin is responsible for binding IP_3 receptor to CD44v10 at lipid rafts and subsequently triggering HA/CD44v10-mediated intracellular calcium (Ca^{2+}) mobilization leading to a variety of endothelial cell functions such as nitric oxide (NO) production, cell adhesion and proliferation.
Further analyses indicate (i) disruption of lipid rafts by depleting cholesterol from the membranes of GM7372A cells (using methyl-β-cyclodextrin treatment) or (ii) interference of endogenous ankyrin binding to CD44 and IP_3 receptor using overexpression of ARD fragments (by transfecting cells with ARDcDNA) not only abolishes ankyrin/IP_3 receptor accumulation into CD44v10/cholesterol-containing lipid rafts, but also blocks HA-mediated Ca^{2+} signaling and endothelial cell functions. Taken together, our findings suggest that CD44v10 interaction with ankyrin and IP_3 receptor in cholesterol-containing lipid rafts plays an important role in regulating HA-mediated Ca^{2+} signaling and endothelial cell functions such as NO production, cell adhesion and proliferation.

3.486 Heparan sulphate proteoglycans modulate fibroblast growth factor-2 binding through a lipid-raft-mediated mechanism

Chu, C.L., Buczek-Thomas, J.A. and Nugent, M.A.
Biochem. J., ***379***, *331-341 (2004)*

We investigated how lipid raft association of HSPG (heparan sulphate proteoglycans) modulates FGF-2 (fibroblast growth factor-2/basic fibroblast growth factor) interactions with vascular smooth-muscle cells. When lipid rafts were disrupted with sterol-binding agents, methyl-alpha-cyclodextrin and filipin, FGF-2 binding to HSPG was reduced 2-5-fold, yet the amount and turnover of cell-surface HSPG were unaffected. Approx. 50-65% of bound FGF-2 was in lipid raft-associated fractions based on insolubility in unlabelled Triton X-100 and flotation in OptiPrep density gradients, and this level was increased with higher FGF-2 concentrations. Less FGF-2 (50-90%) was associated in raft fractions when cholesterol was depleted or HSPG were degraded with heparinase III. To investigate how lipid raft-HSPG interactions altered binding, we compared the rates of FGF-2 dissociation with native, MbetaCD (methyl-beta-cyclodextrin)- and filipin-treated cells. We found that FGF-2 dissociation rates were increased when lipid rafts were disrupted. These results suggest that localization of HSPG within lipid rafts creates high local concentrations of binding sites such that dissociation of FGF-2 is hindered. The localization of FGF-2 and HSPG to lipid rafts also correlated with the activation of protein kinase Calpha. Thus raft association of HSPG might create growth factor traps resulting in increased binding and signal transduction to enhance cell sensitivity.

3.487 Lipid rafts and integrin activation regulate oligodendrocyte survival
Decker, L. and ffrench-Constant, C.
J. Neurosci., ***24(15)*** *3816-3825 (2004)*

Newly formed oligodendrocytes in the CNS derive survival cues from their target axons. These cues are provided in part by laminins expressed on the axon, which are recognized by $\alpha 6\beta 1$ integrin on the oligdendrocyte and amplify platelet-derived growth factor (PDGF) signaling through the phosphatidylinositol 3'-kinase (PI3K) pathway. The $\alpha 6\beta 1$ integrin is localized in oligodendrocyte lipid rafts. We show here using the sphingolipid synthesis inhibitor fumonisin-B1 to deplete rafts that this localization is important for normal survival signaling, because depletion increases oligodendrocyte apoptosis and inhibits PI3K signaling. We have shown previously that PDGF-mediated integrin activation is an important component of oligodendrocyte proliferation signaling, and here we present evidence that a similar mechanism operates in survival signaling. Integrin activation using manganese increases raft localization and rescues the effects of both raft depletion and PDGF removal on survival and PI3K signaling. Together, these results point to an essential role for rafts in oligodendrocyte survival signaling on the basis of the provision of a favorable environment for growth factor-mediated integrin activation.

3.488 Regulated membrane trafficking of the insulin-responsive glucose transporter 4 in adipocytes
Watson, R.T., Kanzaki, M. and Pessin, J.E.
Endocrine Reviews, ***25****, 177-204 (2004)*

Since the discovery of insulin roughly 80 yr ago, much has been learned about how target cells receive, interpret, and respond to this peptide hormone. For example, we now know that insulin activates the tyrosine kinase activity of its cell surface receptor, thereby triggering intracellular signaling cascades that regulate many cellular processes. With respect to glucose homeostasis, these include the function of insulin to suppress hepatic glucose production and to increase glucose uptake in muscle and adipose tissues, the latter resulting from the translocation of the glucose transporter 4 (GLUT4) to the cell surface membrane. Although simple in broad outline, elucidating the molecular intricacies of these receptor-signaling pathways and membrane-trafficking processes continues to challenge the creative ingenuity of scientists, and many questions remain unresolved, or even perhaps unasked. The identification and functional characterization of specific molecules required for both insulin signaling and GLUT4 vesicle trafficking remain key issues in our pursuit of developing specific therapeutic agents to treat and/or prevent this debilitating disease process. To this end, the combined efforts of numerous research groups employing a range of experimental approaches has led to a clearer molecular picture of how insulin regulates the membrane trafficking of GLUT4.

3.489 Activation of the tumor suppresor merlin modulates its interaction with lipid rafts
Stickney, J.T., Bacon, W.C., Rojas, M., Ratner, N. and Ip W.
Cancer Res., ***64****, 2717-2724 (2004)*

Neurofibromatosis type 2 (NF2) is a genetic disorder characterized by bilateral schwannomas of the eighth cranial nerve. The *NF2* tumor suppressor protein, merlin, is related to the ERM (ezrin, radixin, and moesin) family of membrane/F-actin linkers. Merlin resists solubilization by the detergent Triton X-100 (TX-100), a property commonly attributed to association with the cytoskeleton. Accordingly, NF2 patient mutations that encode merlins with enhanced TX-100 solubility have been explained previously in terms of loss of cytoskeletal attachment. However, here we present data to suggest that the detergent resistance of merlin is a result of its constitutive residence in lipid rafts. Furthermore, when cells are grown to high density, merlin shifts to a more buoyant lipid raft fraction in a density gradient. This shift is mimicked in subconfluent cells treated with cytochalasin D, suggesting that the shift results from merlin dissociation from the actin cytoskeleton, but not from lipid rafts. Intramolecular NH_2- and COOH-terminal binding, which occurs when merlin transitions to the growth-suppressive form, also brings about a similar change in buoyant density. Our results suggest that constitutive residence of merlin in lipid rafts is crucial for its function and that as merlin becomes growth suppressive *in vivo*, one significant molecular event may be the loss of interaction with the actin cytoskeleton. To our knowledge, merlin is the first tumor suppressor known to reside within lipid rafts, and the significance of this finding is underscored by known loss-of-function NF2 patient mutations that encode merlins with enhanced TX-100 solubility.

3.490 **Carbachol regulation of rabbit ileal brush border Na^+-H^+ exchanger 3 (NHE3) occurs through changes in NHE3 trafficking and complex formation and is Src dependent**
Li, X. et al
J. Physiol., ***3***, *791-804 (2004)*

The epithelial brush border membrane (BBM) Na^+-H^+ exchanger 3 (NHE3) is the major transport protein responsible for ileal electroneutral Na^+ absorption. We have previously shown that ileal BBM NHE3 activity is rapidly inhibited by carbachol, an agonist that mimics cholinergic activation in digestion. In this study, we investigated the mechanisms involved in this NHE3 inhibition. Carbachol decreased the amount of ileal Na^+ absorptive cell BBM NHE3 within 10 min of exposure. Based on **OptiPrep** gradient centrifugation, carbachol increased the amount of NHE3 in early endosomes and decreased the amount of NHE3 in BBM, consistent with effects on NHE3 trafficking. The decrease in BBM NHE3 occurred in the detergent-soluble BBM fraction with no change in the amount of NHE3 in the BBM detergent-resistant membranes. The size of BBM NHE3 complexes increased in carbachol-exposed ileum, as studied with sucrose gradient centrifugation. The NHE3 complex size increased in the total BBM, but did not change in the detergent-soluble fraction. This suggests that carbachol treatment enhanced the association of proteins with NHE3 complexes specifically in the detergent-resistant fraction of ileal BBM. NHERF2, α-actinin-4 and protein kinase C were among those NHE3-associated proteins because they were more efficiently coimmunoprecipitated from total BBM after carbachol treatment. Moreover, Src was involved in the carbachol-mediated inhibition since: (1) c-Src was rapidly activated in the detergent-resistant membranes by carbachol; and (2) carbachol inhibition of ileal Na^+ absorption was completely abolished by the Src family inhibitor 4-amino-5-(4-chlorophenyl)-7-(*t*-butyl)pyrazolo[3,4-*d*]pyrimidine (PP2). Moreover, the carbachol-induced increase in the size of NHE3-containing complexes was reversed by PP2. These data demonstrate that regulation of NHE3 activity by carbachol can be achieved at several interrelated levels: (1) the subcellular level, at which NHE3 is rapidly endocytosed from BBM to endocytic vesicles upon treatment with carbachol; (2) multiple BBM pools, in which carbachol selectively decreases the amount of NHE3 in the BBM detergent-soluble fraction but not the detergent-resistant membrane; and (3) the molecular level, at which NHE3 complex-associated proteins can be changed upon carbachol treatment, with carbachol leading to larger BBM NHE3 complexes and increased co-IP of NHERF2 with α-actinin-4 and activated PKC. The study further describes NHE3 presence simultaneously in multiple dynamic BBM pools in which NHE3 distribution and associated proteins are altered as part of carbachol-induced and Src-mediated rapid signal transduction, which decreases the amount of BBM NHE3 and thus inhibits NHE3 activity.

3.491 **Ubiquitin-mediated targeting of a mutant plasma membrane ATPase, Pma1-7, to the endosomal/vacuolar system in yeast**
Pizzirusso, M. and Chang, A.
Mol. Biol. Cell, ***15***, *2401-2409 (2004)*

Pma1-7 is a mutant plasma membrane ATPase that is impaired in targeting to the cell surface at 37°C and is delivered instead to the endosomal/vacuolar pathway for degradation. We have proposed that Pma1-7 is a substrate for a Golgibased quality control mechanism. By contrast with wild-type Pma1, Pma1-7 is ubiquitinated. Ubiquitination and endosomal targeting of Pma1-7 is dependent on the Rsp5-Bul1-Bul2 ubiquitin ligase protein complex but not the transmembrane ubiquitin ligase Tul1. Analysis of Pma1-7 ubiquitination in mutants blocked in protein transport at various steps of the secretory pathway suggests that ubiquitination occurs after ER exit but before endosomal entry. In the absence of ubiquitination in *rsp5-1* cells, Pma1-7 is delivered to the cell surface and remains stable. Nevertheless, Pma1-7 remains impaired in association with detergent-insoluble glycolipid-enriched complexes in *rsp5-1* cells, suggesting that ubiquitination is not the cause of Pma1-7 exclusion from rafts. In *vps1* cells in which protein transport into the endosomal pathway is blocked, Pma1-7 is routed to the cell surface. On arrival at the plasma membrane in *vps1* cells, Pma1-7 remains stable and its ubiquitination disappears, suggesting deubiquitination activity at the cell surface. We suggest that Pma1-7 sorting and fate are regulated by ubiquitination.

3.492 **Rotavirus RRV associates with lipid membrane microdomains during cell entry**
Isa, P., Realpe, M., Romero, P., Lopez, S. and Arias, C.F.

*Virology, **322**, 370-381 (2004)*

Rotavirus cell entry is a multistep process, not completely understood, which requires at least four interactions between the virus and cell surface molecules. In this work, we investigated the role of the sphingolipid- and cholesterol-enriched lipid microdomains (rafts) in the entry of rotavirus strain RRV to MA104 cells. We found that ganglioside GM1, integrin subunits α2 and β3, and the heat shock cognate protein 70 (hsc70), all of which have been implicated as rotavirus receptors, are associated with TX-100 and Lubrol WX detergent-resistant membranes (DRMs). Integrin subunits α2 and β3 were found to be particularly enriched in DRMs resistant to lysis by Lubrol WX. When purified RRV particles were incubated with cells at 4 °C, about 10% of the total infectious virus was found associated with DRMs, and the DRM-associated virus increased to 37% in Lubrol-resistant membrane domains after 60-min incubation at 37 °C. The virus was excluded from DRMs if the cells were treated with methyl-β-cyclodextrin (MβCD). Immunoblot analysis of the viral proteins showed that the virus surface proteins became enriched in DRMs upon incubation at 37 °C, being almost exclusively localized in Lubrol-resistant DRMs after 60 min. These data suggest that detergent-resistant membrane domains play an important role in the cell entry of rotaviruses, which could provide a platform to facilitate the efficient interaction of the rotavirus receptors with the virus particle.

3.493 Tula hantavirus L protein is a 250 kDa perinuclear membrane-associated protein
Kukkonen, S.K.J., Vaheri, A. And Plyusin, A.
*J. Gen. Virol., **85**, 1181-1189 (2004)*

The complete open reading frame of Tula hantavirus (TULV) L RNA was cloned in three parts. The middle third (nt 2191–4344) could be expressed in *E. coli* and was used to immunize rabbits. The resultant antiserum was then used to immunoblot concentrated TULV and infected Vero E6 cells. The L protein of a hantavirus was detected, for the first time, in infected cells and was found to be expressed as a single protein with an apparent molecular mass of 250 kDa in both virions and infected cells. Using the antiserum, the expression level of the L protein was followed and image analysis of immunoblots indicated that there were 10^4 copies per cell at the peak level of expression. The antiserum was also used to detect the L protein in cell fractionation studies. In cells infected with TULV and cells expressing recombinant L, the protein pelleted with the microsomal membrane fraction. The membrane association was confirmed with membrane flotation assays. To visualize L protein localization in cells, a fusion protein of L and enhanced green fluorescent protein, L–EGFP, was expressed in Vero E6 cells with a plasmid-driven T7 expression system. L–EGFP localized in the perinuclear region where it had partial co-localization with the Golgi matrix protein GM130 and the TULV nucleocapsid protein.

3.494 Cholesterol-independent interactions with CD47 enhance $\alpha_v\beta_3$ activity
McDonald, J.F., Zheleznyak, A. and Frazier, W.A.
*J. Biol. Chem., **279(17)**, 17301-17311 (2004)*

Expression in OV10 cells of either wild-type CD47 or its extracellular IgV domain linked to a glycosylphosphatidylinositol anchor-(IgV-GPI) enhanced ligand-induced $\alpha_v\beta_3$ activation as detected by the binding of LIBS1 and LIBS6 mAbs. The amplitude of LIBS binding was greater with both CD47 and IgV-GPI expression, indicating an increase in the population of "activable" integrin molecules. Expression of either CD47 species also increased $\alpha_v\beta_3$-mediated adhesion to vitronectin, and to surfaces coated with the anti-β_3 antibody AP3, because of enhanced clustering of $\alpha_v\beta_3$ as confirmed by chemical cross-linking. Cholesterol depletion with methyl-β-cyclodextrin did not prevent the increase in anti-LIBS binding, but reduced cell adhesion to vitronectin and AP3. However, cells expressing CD47 were partially insulated against this disruption, and IgV-GPI was even more effective. Both CD47 and IgV-GPI were found in cholesterol-rich rafts prepared in the absence of detergent, but only CD47 could recruit $\alpha_v\beta_3$ and its associated signaling molecules to these domains. Thus CD47-$\alpha_v\beta_3$ complexes in cholesterol-rich raft domains appear to engage in G_i-dependent signaling whereas CD47-$\alpha_v\beta_3$ interactions that lead to integrin clustering are also detergent resistant, but are insensitive to cholesterol depletion and do not require the transmembrane region of CD47.

3.495 Brain-specific deletion of neuropathy target esterase/*swisscheese* results in neurodegeneration
Akassoglou, K. et al
*PNAS, **101(14)**, 5075-5080 (2004)*

Neuropathy target esterase (NTE) is a neuronal membrane protein originally identified for its property to be modified by organo-phosphates (OPs), which in humans cause neuropathy characterized by axonal degeneration. *Drosophila* mutants for the homolog gene of *NTE, swisscheese* (*sws*), indicated a possible involvement of *sws* in the regulation of axon-glial cell interaction during glial wrapping. However, the role of NTE/*sws* in mammalian brain pathophysiology remains unknown. To investigate NTE function *in vivo*, we used the cre/loxP site-specific recombination strategy to generate mice with a specific deletion of NTE in neuronal tissues. Here we show that loss of NTE leads to prominent neuronal pathology in the hippocampus and thalamus and also defects in the cerebellum. Absence of NTE resulted in disruption of the endoplasmic reticulum, vacuolation of nerve cell bodies, and abnormal reticular aggregates. Thus, these results identify a physiological role for NTE in the nervous system and indicate that a loss-of-function mechanism may contribute to neurodegenerative diseases characterized by vacuolation and neuronal loss.

3.496 The G protein-coupled receptor rhodosin in the native membrane
Fotiadis, D. et al
*FEBS Lett., **564**, 281-288 (2004)*

The higher-order structure of G protein-coupled receptors (GPCRs) in membranes may involve dimerization and formation of even larger oligomeric complexes. Here, we have investigated the organization of the prototypical GPCR rhodopsin in its native membrane by electron and atomic force microscopy (AFM). Disc membranes from mice were isolated and observed by AFM at room temperature. In all experimental conditions, rhodopsin forms structural dimers organized in paracrystalline arrays. A semi-empirical molecular model for the rhodopsin paracrystal is presented validating our previously reported results. Finally, we compare our model with other currently available models describing the supramolecular structure of GPCRs in the membrane.

3.497 Copatching and lipid raft association of different viral glycoproteins expressed on the surfaces of Pseudorabies virus-infected cells
Favoreel, H.W., Mettenleiter, T.C. and Nauwynck, H.J.
*J. Virol., **78(10)**, 5279-5287 (2004)*

Pseudorabies virus (PRV) is a swine alphaherpesvirus that is closely related to human herpes simplex virus (HSV). Both PRV and HSV express a variety of viral envelope glycoproteins in the plasma membranes of infected cells. Here we show that at least four major PRV glycoproteins (gB, gC, gD, and gE) in the plasma membrane of infected swine kidney cells and monocytes seem to be linked, since monospecific antibody-induced patching of any one of these proteins results in copatching of the others. Further, for all four PRV glycoproteins, monospecific antibody-induced patches were enriched in GM1, a typical marker of lipid raft microdomains, but were excluded for transferrin receptor, a nonraft marker, suggesting that these viral proteins may associate with lipid rafts. However, only gB and, to a lesser extent, gE were found in lipid raft fractions by using detergent floatation assays, indicating that gC and gD do not show strong lipid raft association. Addition of methyl-ß-cyclodextrin (MCD), a cholesterol-depleting agent that is commonly used to disrupt lipid rafts, only slightly reduced copatching efficiency between the different viral proteins, indicating that other factors, perhaps tegument-glycoprotein interactions, may be important for the observed copatching events. On the other hand, MCD strongly reduced polarization of the antibody-induced viral glycoprotein patches to a cap structure, a gE-dependent process that has been described for specific PRV- and HSV-infected cells. Therefore, we hypothesize that efficient gE-mediated capping of antibody-antigen patches may require the lipid raft-associated signal transduction machinery.

3.498 Endogenous SHIP2 does not localize in lipid rafts in 3T3-L1 adipocytes
Jacobs, C., Onnockx, S., Vandenbroere, I. and Pirson, I.
*FEBS Lett., **565**, 70-74 (2004)*

SH2 domain containing inositol polyphosphate 5-phosphatase (SHIP2) dephosphorylates phosphatidylinositol 3,4,5-trisphosphate (PtdIns(3,4,5)P_3) into phosphatidylinositol 3,4-bisphosphate (PtdIns(3,4)P_2). SHIP2 knock-out mice demonstrated that SHIP2 acts as a negative regulator of insulin cascade in vivo. Our two-hybrid study showed that SHIP2 interacts with c-Cbl associated protein (CAP) and c-Cbl, implicated in the insulin signaling. As some proteins implicated in insulin signaling, like insulin receptor, CAP, c-Cbl or TC10, were reported to localize in lipid rafts, we addressed the same question for SHIP2. SHIP2 was detected in the non-raft fraction in CHO-IR, C2C12 myotubes and 3T3-L1 adipocytes except when it is overexpressed in CHO-IR, where we detected SHIP2 in the raft fraction.

3.499 Uptake and transsport of high-density lipoprotein (HDL) and HDL-associated α-tocopherol by an *in vitro* blood-brain barrier model
Balazs, Z. et al
J. Neurochem., ***89***, *939-950 (2004)*

The present study aimed to investigate pathways that contribute to uptake and transcytosis of high-density lipoproteins (HDLs) and HDL-associated α-tocopherol (αTocH) across an *in vitro* model of the blood-brain barrier (BBB). In primary porcine brain capillary endothelial cells HDL-associated αTocH was taken up in 10-fold excess of HDL holoparticles, indicating efficient selective uptake, a pathway mediated by scavenger receptor class B, type I (SR-BI). SR-BI was present in caveolae of brain capillary endothelial cells and expressed almost exclusively at the apical membrane. Disruption of caveolae with methyl-β-cyclodextrin (CDX) resulted in (mis)sorting of SR-BI to the basolateral membrane. Immunohistochemistry of porcine brain cryosections revealed SR-BI expression on brain capillary endothelial cells and presumably astrocytic endfeet. HDL-associated [^{14}C]αTocH taken up by brain capillary endothelial cells was recovered in sucrose gradient fractions containing the majority of cellular caveolin-1, the major caveolae-associated protein. During mass transfer studies using αTocH-enriched HDL, approximately 50% of cellular αTocH was recovered with the bulk of cellular caveolin-1 and SR-BI. Efflux experiments revealed that a substantial amount of cell-associated [^{14}C]αTocH could be mobilized into the culture medium. In addition, apical-to-basolateral transport of HDL holoparticles and HDL-associated αTocH was saturable. Results from the present study suggest that part of cerebral apolipoprotein A-I and αTocH originates from plasma HDL transcytosed across the BBB and that caveolae-located SR-BI facilitates selective uptake of HDL-associated αTocH at the BBB.

3.500 Caveolar and lipid raft localization of the growth hormone receptor ans its signaling elements
Yang, N., Huang, Y., Jiang, J. And Frank, S.J.
J. Biol. Chem., ***279(20)***

The growth hormone receptor (GHR) is a cell surface receptor that mediates the somatogenic and metabolic effects of the growth hormone (GH). GHR signaling is transduced via the receptor-associated cytoplasmic tyrosine kinase called Janus protein kinase 2 (JAK2). The major intracellular signaling systems activated by JAK2 in response to GH include the signal transducer and activator of transcription (STAT) 5 and extracellular signal-regulated kinase (ERK)-1 and -2 pathways. In this report, we investigate the role of cholesterol-rich plasma membrane microdomains (caveolae and lipid rafts) in GH signaling. By subcellular fractionation of the GH-responsive 3T3-F442A murine preadipocyte, we found dramatic enrichment (6.7-fold) of plasma membrane GHR in the caveolae membranes (CM). JAK2 was also represented in the CM fraction, but was less enriched (2.5-fold) than GHR. ERK1/2 and the important ERK pathway upstream small adaptor protein, Grb2 (growth factor receptor-bound protein 2), were also enriched in caveolae (2.3- and 8.3-fold, respectively), but STAT5 was barely detected in the same fraction. Correspondingly, GH-induced tyrosine-phosphorylated GHR, JAK2, and ERK1/2 were highly represented in the CM fraction, whereas tyrosine-phosphorylated STAT5 was enriched in the non-membranous fraction of the post-nuclear supernatant. Additionally, GH induced further accumulation of GHR, Grb2, and SHC proteins in the CM fraction. Interestingly, treatment of the cells with the caveolae-disrupting agent, methyl-β-cyclodextrin (mβCD), selectively inhibited GH-induced ERK1/2 activation but not STAT5 phosphorylation; repletion of cholesterol in mβCD-treated cells restored GH-induced ERK activation. Comparison of 3T3-F442A cells with the GHR-expressing human IM-9 lymphoblasts revealed similar enrichment of GHR in the lipid raft fraction of IM-9 as in the CM fraction of 3T3-F442A, but there were dramatic differences in the ERKs and Grb2. The IM-9 cell, in which ERKs are not activated by GH, displayed no enrichment of ERKs and Grb2 in the lipid raft fraction. Our results suggest that localization of GHRs in the CM fraction of the plasma membrane plays important roles in signaling.

3.501 A role for myosin-1A in the localization of a brush border disaccharidase
Tyska, M.J. and Mooseker, M.S.
J. Cell Biol., ***165(3)***, *395-405 (2004)*

To gain insight regarding myosin-1A (M1A) function, we expressed a dominant negative fragment of this motor in the intestinal epithelial cell line, CACO-2_{BBE}. Sucrase isomaltase (SI), a transmembrane disaccharidase found in microvillar lipid rafts, was missing from the brush border (BB) in cells expressing

this fragment. Density gradient centrifugation, affinity purification, and immunopurification of detergent-resistant membranes isolated from CACO-2_{BBE} cells and rat microvilli (MV) all indicate that M1A and SI reside on the same population of low density (~1.12 g/ml) membranes. Chemical cross-linking of detergent-resistant membranes from rat MV indicates that SI and M1A may interact in a lipid raft complex. The functional significance of such a complex is highlighted by expression of the cytoplasmic domain of SI, which results in lower levels of M1A and a loss of SI from the BB. Together, these studies are the first to assign a specific role to M1A and suggest that this motor is involved in the retention of SI within the BB.

3.502 Svp1p defines a family of phosphatidylinositol 3,5-bisphosphate effectors
Dove, S.K. et al
*EMBO J., **23**, 1922-1933 (2004)*

Phosphatidylinositol 3,5-bisphosphate (PtdIns(3,5)P_2), made by Fab1p, is essential for vesicle recycling from vacuole/lysosomal compartments and for protein sorting into multivesicular bodies. To isolate PtdIns(3,5)P_2 effectors, we identified *Saccharomyces cerevisiae* mutants that display *fab1*Δ-like vacuole enlargement, one of which lacked the *SVP1/*YFR021w/*ATG18* gene. Expressed Svp1p displays PtdIns(3,5)P_2 binding of exquisite specificity, GFP-Svp1p localises to the vacuole membrane in a Fab1p-dependent manner, and *svp1*Δ cells fail to recycle a marker protein from the vacuole to the Golgi. Cells lacking Svp1p accumulate abnormally large amounts of PtdIns(3,5)P_2. These observations identify Svp1p as a PtdIns(3,5)P_2 effector required for PtdIns(3,5)P_2-dependent membrane recycling from the vacuole. Other Svp1p-related proteins, including human and *Drosophila* homologues, bind PtdIns(3,5)P_2 similarly. Svp1p and related proteins almost certainly fold as ß-propellers, and the PtdIns(3,5)P_2-binding site is on the ß-propeller. It is likely that many of the Svp1p-related proteins that are ubiquitous throughout the eukaryotes are PtdIns(3,5)P_2 effectors. Svp1p is not involved in the contributions of *FAB1*/PtdIns(3,5)P_2 to MVB sorting or to vacuole acidification and so additional PtdIns(3,5)P_2 effectors must exist.

3.503 Differential regulation of cytosolic and peroximal bile acid amidation by PPARα activation favors the formation of unconjugated bile acids
Solaas, K. et al
*J. Lipid. Res.,**45**, 1051-1060 (2004)*

In human liver, unconjugated bile acids can be formed by the action of bile acid-CoA thioesterases (BACTEs), whereas bile acid conjugation with taurine or glycine (amidation) is catalyzed by bile acid-CoA:amino acid *N*-acyltransferases (BACATs). Both pathways exist in peroxisomes and cytosol. Bile acid amidation facilitates biliary excretion, whereas the accumulation of unconjugated bile acids may become hepatotoxic. We hypothesized that the formation of unconjugated and conjugated bile acids from their common substrate bile acid-CoA thioesters by BACTE and BACAT is regulated via the peroxisome proliferator-activated receptor α(PPARα). Livers from wild-type and PPARα-null mice either untreated or treated with the PPARα activator WY-14,643 were analyzed for BACTE and BACAT expression. The total liver capacity of taurochenodeoxycholate and taurocholate formation was decreased in WY-14,643-treated wild-type mice by 60% and 40%, respectively, but not in PPARα-null mice. Suppression of the peroxisomal BACAT activity was responsible for the decrease in liver capacity, whereas cytosolic BACAT activity was essentially unchanged by the treatment. In both cytosol and peroxisomes, the BACTE activities and protein levels were upregulated 5- to 10-fold by the treatment. These effects caused by WY-14,643 treatment were abolished in PPARα-null mice.
The results from this study suggest that an increased formation of unconjugated bile acids occurs during PPARα activation.

3.504 Passive and active inclusion of host proteins in human immunodeficiency virus type 1 Gag particles during budding at the plasma membrane
Hammerstedt, M. and Garoff, H.
*J. Virol., **78(11)**, 5686-5697 (2004)*

Human immunodeficiency virus type 1 particles form by budding at the surface of most cell types. In this process, a piece of the plasma membrane is modified into an enveloped virus particle. The process is driven by the internal viral protein $Pr55^{gag}$. We have studied how host proteins in the membrane are dealt with by $Pr55^{gag}$ during budding. Are they included in or excluded from the particle? The question was approached by measuring the relative concentrations of host and viral proteins in the envelope of $Pr55^{gag}$ particles and in their donor membranes in the cell. We observed that the bulk of the host proteins, including actin and clathrin, were passively included into the virus-like Gag particles. This result suggests that budding by

$Pr55^{gag}$ proceeds without significant alteration of the original host protein composition at the cell membrane. Nevertheless, some proteins were concentrated in the particles, and a few were excluded. The concentrated proteins included cyclophilin A and Tsg-101. These were recruited to the plasma membrane by $Pr55^{gag}$. The membrane-bound cyclophilin A was concentrated into particles as efficiently as $Pr55^{gag}$, whereas Tsg-101 was concentrated more efficiently. The latter finding is consistent with a role for Tsg-101 in Gag particle release.

3.505 Functions of pancreatic β cells and adipocytes in bombesin receptor subtype-3-deficient mice
Nakamichi, Y. et al
Biochem. Biophys. Res. Comm., ***318***, *698-703 (2004)*

We previously reported that mice lacking bombesin receptor subtype-3 (BRS-3) exhibit mild late-onset obesity and glucose intolerance [Nature 390 (1997) 160]. To examine the mechanism by which glucose intolerance is developed in these mice, we studied insulin release and proinsulin biosynthesis in isolated pancreatic islets and glucose uptake and facilitative glucose transporter (GLUT)-4 translocation in adipose tissues. Although islet insulin contents and the size and number of islets of Langerhans in BRS-3-deficient mice decreased, there was no difference in glucose-stimulated insulin release and proinsulin biosynthesis between BRS-3-deficient and wild-type control mice. In contrast, adipose tissues exhibited a marked difference: the uptake of [^{14}C]2-deoxy-D-glucose by adipocytes isolated from BRS-3-deficient mice was not stimulated by 10^{-7} M insulin addition, and membrane fractionation analysis showed that GLUT4 was barely detected in the fraction of plasma membrane in BRS-3-deficient mice in the presence of 10^{-7} M insulin. Quantitative reverse transcription-PCR (RT-PCR) showed that mRNA levels of GLUT4, insulin receptor, insulin receptor substrate (IRS)-1 and IRS-2, syntaxin 4, SNAP23, and VAMP-2 in adipose tissues of BRS-3-deficient mice were unchanged compared with those in wild-type control mice. We concluded that impaired glucose metabolism observed in BRS-3-deficient mice was mainly caused by impaired GLUT4 translocation in adipocytes.

3.506 Analysis of lipid rafts in T cell
Thomas, S., Preda-Pais, A., Casares, S. and Brumeanu, T-D.
Mol. Immunol., ***41***, *399-409 (2004)*

The plasma membrane of T cells is made of a combination of glycosphingolipids and protein receptors organized in glycolipoprotein microdomains termed lipid rafts. The structural assembly of lipid rafts was investigated by various physical and biochemical assays. Depending on the differentiation status of T cells, the lipid rafts seclude various protein receptors involved in T cell signaling, cytoskeleton reorganization, membrane trafficking, and the entry of infectious organisms into the cells. This review article summarizes the most common methods, and their limits and advantages for analyzing the composition and assembly of lipid rafts with protein receptors into lipid rafts microdomains in plasma membrane of T cells. It also includes new methods such as ELISA/Polysorp and flow cytometry, and a combined sucrose gradient centrifugation–FPLC–Western blot strategy developed in our laboratory to study non-covalent interactions between the GM1 glycosphingolipid and protein receptors in plasma membrane of T cells.

3.507 Functional domains in presenilin. The TYR-288 residue controls γ-secretase activity and endoprotoeolysis
Laudon, H. et al
J. Biol. Chem., ***279(23)***, *23925-23932 (2004)*

Processing of the Alzheimer amyloid precursor protein (APP) into the amyloid β-protein and the APP intracellular domain is a proteolysis event mediated by the γ-secretase complex where presenilin (PS) proteins are key constituents. PS is subjected to an endoproteolytic cleavage, generating a stable heterodimer composed of an N-terminal and a C-terminal fragment. Here we aimed at further understanding the role of PS in endoproteolysis, in proteolytic processing of APP and Notch, and in assembly of the γ-secretase complex. By using a truncation protocol and alanine scanning, we identified Tyr-288 in the PS1 N-terminal fragment as critical for PS-dependent intramembrane proteolysis. Further mutagenesis of the 288 site identified mutants differentially affecting endoproteolysis and γ-secretase activity. The Y288F mutant was endoproteolyzed to the same extent as wild type PS but increased the amyloid β-protein 42/40 ratio by ~75%. In contrast, the Y288N mutant was also endoproteolytically processed but was inactive in reconstituting γ-secretase in PS null cells. The Y288D mutant was deficient in both endoproteolysis and γ-secretase activity. All three mutant PS1 molecules were incorporated into γ-secretase complexes and stabilized Pen-2 in PS null cells. Thus, mutations at Tyr-288 do not affect γ-secretase complex assembly but can differentially control endoproteolysis and γ-secretase activity.

3.508 The T cell receptor γ chain alternate reading frame protein (TARP), a prostate-specific protein localized in mitochondria

Maeda, H. et al

J. Biol. Chem., ***279(23)***, *24561-24568 (2004)*

We previously showed that mRNA encoding TARP (T cell receptor γ chain alternate reading frame protein) is exclusively expressed in the prostate in males and is up-regulated by androgen in LNCaP cells, an androgen-sensitive prostate cancer cell line. We have now developed an anti-TARP monoclonal antibody named TP1, and show that TARP protein is up-regulated by androgen in both LNCaP and MDA-PCa-2b cells. We used TP1 to determine the subcellular localization of TARP by Western blotting following subcellular fractionation and immunocytochemistry. Both methods showed that TARP is localized in the mitochondria of LNCaP cells, MDA-PCa-2b cells, and PC-3 cells transfected with a TARP-expressing plasmid. We also transfected a plasmid encoding TARP fused to green fluorescent protein into LNCaP, MDA-Pca-2b, and PC-3 cells and confirmed its specific mitochondrial localization in living cells. Fractionation of mitochondria shows that TARP is located in the outer mitochondrial membrane. Immunohistochemistry using a human prostate cancer sample showed that TP1 reacted in a dot-like cytoplasmic pattern consistent with the presence of TARP in mitochondria. These data demonstrate that TARP is the first prostate-specific protein localizing in mitochondria and indicate that TARP, an androgen-regulated protein, may act on mitochondria to carry out its biological functions.

3.509 Lipid raft polarization contributes to hyphal growth in *Candida albicans*

Martin, S.W. and Konopka, J.B.

*Eukaryotic cell, **3(3)**, 675-684 (2004)*

The polarization of sterol- and sphingolipid-enriched domains (lipid rafts) has been linked to morphogenesis and cell movement in diverse cell types. In the yeast *Saccharomyces cerevisiae*, a dramatic polarization of sterol-rich domains to the shmoo tip was observed in pheromone-induced cells (M. Bagnat and K. Simons, Proc. Natl. Acad. Sci. USA **99:**14183-14188, 2002). We therefore examined whether plasma membrane lipid polarization contributes to the ability of the fungal pathogen *Candida albicans* to grow in a highly polarized manner to form hyphae. Interestingly, staining with filipin revealed that membrane sterols were highly polarized to the leading edge of growth during all stages of hyphal growth. Budding and pseudohyphal cells did not display polarized staining. Filipin staining was also enriched at septation sites in hyphae, where colocalization with septin proteins was observed, suggesting a role for the septins in forming a boundary domain. Actin appeared to play a role in sterol polarization and hyphal morphogenesis in that both were disrupted by low concentrations of latrunculin A that did not prevent budding. Furthermore, blocking either sphingolipid biosynthesis with myriocin or sterol biosynthesis with ketoconazole resulted in a loss of ergosterol polarization and caused abnormal hyphal morphogenesis, suggesting that lipid rafts are involved. Since hyphal growth is required for the full virulence of *C. albicans*, these results suggest that membrane polarization may contribute to the pathogenesis of this organism.

3.510 CD44 interaction with Na^+-H^+ exchanger (NHE1) creates acidic microenvironment leading to hyaluronidase-2 and cathepsin B activation and breast tumor cell invasion

Bourguignon, L.Y.W., Singleton, P.A., Diedrich, F., Stern, R. and Gilad, E.

J. Biol. Chem., ***279(26)***, *26691-27007 (2004)*

We have explored CD44 (a hyaluronan (HA) receptor) interaction with a Na^+-H^+ exchanger (NHE1) and hyaluronidase-2 (Hyal-2) during HA-induced cellular signaling in human breast tumor cells (MDA-MB-231 cell line). Immunological analyses demonstrate that CD44s (standard form) and two signaling molecules (NHE1 and Hyal-2) are closely associated in a complex in MDA-MB-231 cells. These three proteins are also significantly enriched in cholesterol and ganglioside-containing lipid rafts, characterized as caveolin and flotillin-rich plasma membrane microdomains. The binding of HA to CD44 activates Na^+-H^+ exchange activity which, in turn, promotes intracellular acidification and creates an acidic extracellular matrix environment. This leads to Hyal-2-mediated HA catabolism, HA modification, and cysteine proteinase (cathepsin B) activation resulting in breast tumor cell invasion. In addition, we have observed the following: (i) HA/CD44-activated Rho kinase (ROK) mediates NHE1 phosphorylation and activity, and (ii) inhibition of ROK or NHE1 activity (by treating cells with a ROK inhibitor, Y27632, or NHE1 blocker, *S*-(*N*-ethyl-*N*-isopropyl) amiloride, respectively) blocks NHE1 phosphorylation/Na^+-H^+ exchange activity, reduces intracellular acidification, eliminates the acidic environment in the extracellular matrix, and suppresses breast tumor-specific behaviors (*e.g.* Hyal-2-mediated HA modification, cathepsin B

activation, and tumor cell invasion). Finally, down-regulation of CD44 or Hyal-2 expression (by treating cells with CD44 or Hyal-2-specific small interfering RNAs) not only inhibits HA-mediated CD44 signaling (*e.g.* ROK-mediated Na^+-H^+ exchanger reaction and cellular pH changes) but also impairs oncogenic events (*e.g.* Hyal-2 activity, hyaluronan modification, cathepsin B activation, and tumor cell invasion). Taken together, our results suggest that CD44 interaction with a ROK-activated NHE1 (a Na^+-H^+ exchanger) in cholesterol/ganglioside-containing lipid rafts plays a pivotal role in promoting intracellular/extracellular acidification required for Hyal-2 and cysteine proteinase-mediated matrix degradation and breast cancer progression.

3.511 Carboxyl ester lipase cofractionates with scavenger receptor BI in hepatocyte lipid rafts and enhances selective uptake and hydrolysis of cholesteryl esters from HDL_3
Camarota, L.M., Chapman, J.M., Hui, D.Y. and Howles, P.N.
J. Biol. Chem., ***279(26)***, *27599-27606 (2004)*

Cholesteryl esters are selectively removed from high density lipoproteins by hepatocytes and steroidogenic cells through a process mediated by scavenger receptor BI. In the liver this cholesterol is secreted into bile, primarily as free cholesterol. Previous work showed that carboxyl ester lipase enhanced selective uptake of cholesteryl ether from high density lipoprotein by an unknown mechanism. Experiments were performed to determine whether carboxyl ester lipase plays a role in scavenger receptor BI-mediated selective uptake. When added to cultures of HepG2 cells, carboxyl ester lipase cofractionated with scavenger receptor BI and [^{3}H]cholesteryl ether-labeled high density lipoprotein in lipid raft fractions of cell homogenates. Confocal microscopy of immunostained carboxyl ester lipase and scavenger receptor BI showed a close association of these proteins in HepG2 cells. The enzyme and receptor also cofractionated from homogenates of mouse liver using two different fractionation methods. Antibodies that block scavenger receptor BI function prevented carboxyl ester lipase stimulation of selective uptake in primary hepatocytes from carboxyl ester lipase knockout mice. Heparin blockage of cell-surface proteoglycans also prevented carboxyl ester lipase stimulation of cholesteryl ester uptake by HepG2 cells. Inhibition of carboxyl ester lipase activity in HepG2 cells reduced hydrolysis of high density lipoprotein-cholesteryl esters ~40%. *In vivo*, hydrolysis was similarly reduced in lipid rafts from the livers of carboxyl ester lipase-null mice compared with control animals. Primary hepatocytes from these mice yielded similar results. The data suggest that carboxyl ester lipase plays a physiological role in hepatic selective uptake and metabolism of high density lipoprotein cholesteryl esters by direct and indirect interactions with the scavenger receptor BI pathway.

3.512 PSPN/GFRα4 has a significantly weaker capacity thab GDNF/GFRα1 to recruit RET to rafts, but promotes neuronal survival and neurite outgrowth
Yang, J. et al
FEBS Lett., ***569***, *267-271 (2004)*

Previously, it was shown that the recruitment of RET into lipid rafts by glial cell line-derived neurotrophic factor (GDNF)/GFRα1 is crucial for efficient signal transduction. Here, we show that the mouse GFRα4 is a functional, *N*-glycosylated, glycosylphosphatidylinositol (GPI)-anchored protein, which mediates persephin (PSPN)-induced phosphorylation of RET, but has an almost undetectable capacity to recruit RET into the 0.1% Triton X-100 insoluble membrane fraction. In spite of this, PSPN/mGFRα4 promotes neurite outgrowth in PC6-3 cells and survival of cerebellar granule neurons. As we show that also human PSPN/GFRα4 is unable to recruit RET into lipid rafts, we propose that the mammalian GFRα4 in this respect differs from GFRα1.

3.513 Sphingolipid C4 hydroxylation influences properties of yeast detergent-insoluble glycolipid-enriched membranes
Idkowiak-Baldys, J., Grilley, M.M. and Takemoto, J.Y.
FEBS Lett., ***569***, *272-276 (2004)*

Sphingoid base C4 hydroxylation is required for syringomycin E action on the yeast plasma membrane. Detergent-insoluble glycolipid-enriched membranes (DIGs) from a yeast strain lacking C4 hydroxylated sphingoid bases (*sur2*Δ) are composed of linear membrane fragments instead of vesicular structures observed for wild-type DIGs, though they have similar lipid compositions and amounts of DIG marker proteins. Light-scattering bands collected from *sur2*Δ after centrifugation of Triton X-100-treated cell lysates in continuous density gradients have lower buoyant densities than that of the wild-type. The results

show that C4 hydroxylation influences the physical and structural properties of DIGs and suggest that syringomycin E interacts with lipid rafts.

3.514 Membrane order conservation in raft and non-raft regions of hepatocyte plasma membranes from thermally acclimated rainbow trout
Zehmer, J.K. and Hazel, J.R.
*Biochim, Biophys. Acta., **1664**, 108-116 (2004)*

Homeoviscous adaptation (HVA), the thermal conservation of membrane fluidity/order at different body temperatures, has been observed to varying degrees in different membranes. However, HVA has not been studied in raft and non-raft regions of the plasma membrane (PM) separately. Rafts are ordered PM microdomains implicated in signal transduction, membrane traffic and cholesterol homeostasis. Using infrared spectroscopy, we measured order in raft-enriched PM (raft) and raft-depleted PM (RDPM) isolated from hepatocytes of rainbow trout (*Oncorhynchus mykiss*) acclimated to 5 and 20 °C. We found approximately 130% and 90% order compensation in raft and RDPM, respectively, suggesting their independent regulation. Raft was more ordered than RDPM in the warm-acclimated trout, a difference fully explained by a 58% enrichment of cholesterol, compared to RPDM. Unexpectedly, raft and RDPM from cold-acclimated trout did not differ in cholesterol content or order. Freezing the membrane samples during preparation had no effect on order. Treatment with cyclodextrin depleted cholesterol by 36%, 56%, and 55%, producing significant decreases in order in raft and RDPM from warm-acclimated trout and RDPM from cold-acclimated trout, respectively. However, a 69% depletion of cholesterol from raft from cold-acclimated trout had no significant effect on order. This result, and the lack of a difference in order between raft and RDPM, suggests that raft and non-raft PM in cold-acclimated trout are not spatially segregated by phase separation due to cholesterol.

3.515 Cellular distribution of lysyl-tRNA synthetase and its interaction with Gag during human immunodeficiency virus type 2 assembly
Halwani, R. et al
*J. Virol., **78(14)**, 7553-7564 (2004)*

Lysyl-tRNA synthetase (LysRS) is packaged into human immunodeficiency virus type 1 (HIV-1) via its interaction with Gag, and this enzyme facilitates the selective packaging of $tRNA_3^{Lys}$, the primer for initiating reverse transcription, into HIV-1. The Gag/LysRS interaction is detected at detergent-resistant membrane but not in membrane-free cell compartments that contain Gag and LysRS. LysRS is found (i) in the nucleus, (ii) in a cytoplasmic high-molecular-weight aminoacyl-tRNA synthetase complex (HMW aaRS complex), (iii) in mitochondria, and (iv) associated with plasma membrane. The cytoplasmic form of LysRS lacking the mitochondrial import signal was previously shown to be efficiently packaged into virions, and in this report we also show that LysRS compartments in nuclei, in the HMW aaRS complex, and at the membrane are also not required as a primary source for viral LysRS. Exogenous mutant LysRS species unable to either enter the nucleus or bind to the cell membrane are still incorporated into virions. Many HMW aaRS components are not packaged into the virion along with LysRS, and the interaction of LysRS with p38, a protein that binds tightly to LysRS in the HMW aaRS complex, is not required for the incorporation of LysRS into virions. These data indicate that newly synthesized LysRS may interact rapidly with Gag before the enzyme has the opportunity to move to the above-mentioned cellular compartments. In confirmation of this idea, we found that newly synthesized LysRS is associated with Gag after a 10-min pulse with [^{35}S]cysteine/methionine. This observation is also supported by previous work indicating that the incorporation of LysRS into HIV-1 is very sensitive to the inhibition of new synthesis of LysRS.

3.516 Microtubules regulate angiotensin II type 1 receptor and Rac1 localization in caveolae/lipid rafts
Zuo, L., Ushio-Fukai, M., Hilenski, L.L. and Alexander, R.W.
*Arterioscler. Thromb. Vasc. Biol., **24**, 1223-1228 (2004)*

Objective— Microtubules are important in signal transduction temporal–spatial organization. Full expression of angiotensin II (Ang II) signaling in vascular smooth muscle cells (VSMCs) is dependent on the reactive oxygen species (ROS) derived from nicotinamide-adenine dinucleotide phosphate (NAD(P)H) oxidase and the dynamic association of the Ang II type 1 receptor (AT_1R) with caveolae/lipid rafts. Translocation of the small GTPase Rac1 to the plasma membrane is an essential step for activation of NAD(P)H oxidase; however, its precise localization in the plasma membrane after agonist stimulation and

how it is targeted are unknown. We hypothesized that microtubules are involved in regulating multiphasic Ang II signaling events in VSMC.
Methods and Results— We show that Ang II promotes Rac1 and AT_1R trafficking into caveolae/lipid rafts, which is blocked by disruption of microtubules with nocodazole. As a consequence, nocodazole significantly inhibits Ang II–stimulated H_2O_2 production, its downstream ROS-dependent epidermal growth factor receptor transactivation, Akt phosphorylation, and vascular hypertrophy without affecting Rac1 activation or ROS-independent extracellular signal-regulated kinase 1/2 phosphorylation.
Conclusions— These results suggest that proper Rac1 and AT_1R trafficking into caveolae/lipid rafts requires the integrity of microtubules and provide insight into the essential role of microtubules for the spatial–temporal organization of ROS-dependent and caveolae/lipid rafts–dependent AT_1R signaling linked to vascular hypertrophy.
The role of microtubules in angiotensin II (Ang II) signaling remains unknown. We demonstrate that Ang II promotes Rac1 and Ang II type 1 receptor trafficking into the caveolae/lipid rafts, which requires the integrity of microtubules. We also found that intact microtubules mediate Ang II–stimulated H_2O_2 production, its downstream EGF-R transactivation, Akt phosphorylation, and vascular hypertrophy.

3.517 Stoichiometry of the T-cell receptor-CD3 complex and key intermediates assembled in the endoplasmic reticulum
Call, M.E., Pyrdol, J. and Wucherpfennig, K.W.
*EMBO J., **22**, 2348-2357 (2004)*

The T-cell receptor (TCR)–CD3 complex is critical for T-cell development and function, and represents one of the most complex transmembrane receptors. Models of different stoichiometry and valency have been proposed based on cellular experiments and these have important implications for the mechanisms of receptor triggering. Since determination of receptor stoichiometry in T-cells is not possible due to the presence of previously synthesized, unlabeled receptor components with different half-lives, we examined the stoichiometry of the receptor assembled in endoplasmic reticulum (ER) microsomes of B-cell origin. The stoichiometric relationship among all subunits was directly determined using intact radiolabeled TCR–CD3 complexes that were isolated with a sequential, non-denaturing immunoprecipitation method, and identical results were obtained with two detergents belonging to different structural classes. The results firmly establish that the αß TCR–CD3 complex assembled in the ER is monovalent and composed of one copy of the TCRαß, CD3δε, CD3γε and ζ–ζ dimers.

3.518 PKD1/PKCμ promotes αvβ3 integrin recycling and delivery to nascent focal adhesions
Woods, A.J., White, D.P., Caswell, P.T. and Norman, J.C.
*EMBO J., **23**, 2531-2543 (2004)*

To identify kinases that regulate integrin recycling, we have immunoprecipitated αvß3 integrin from NIH 3T3 fibroblasts in the presence and absence of primaquine (a drug that inhibits receptor recycling and leads to accumulation of integrins in endosomes) and screened for co-precipitating kinases. Primaquine strongly promoted association of αvß3 integrin with PKD1, and fluorescence microscopy indicated that integrin and PKD1 associate at a vesicular compartment that is downstream of a Rab4-dependent transport step. PKD1 association was mediated by the C-terminal region of the ß3 integrin cytodomain, and mutants of ß3 that were unable to recruit PKD1 did not recycle in a PDGF-dependent fashion. Furthermore, suppression of endogenous PKD1 levels by RNAi, or overexpression of catalytically inactive PKD1 inhibited PDGF-dependent recycling of αvß3 from early endosomes to the plasma membrane and blocked recruitment of α vß3 to newly formed focal adhesions during cell spreading. These data indicate that PKD1 influences cell migration by directing vesicular transport of the αvß3 integrin heterodimer.

3.519 Human Doppel and prion protein share common membrane microdomains and internalization pathways
Massimino, M.L. et al
*Int. J. Biochem. and Cell Biol., **36**, 2016-2031 (2004)*

Doppel is the first identified homologue of the prion protein (PrP^c) implicated in prion disease. Doppel is considered an N-truncated form of PrP^c, and shares with PrP^c several structural and biochemical features. When over expressed in the brain of some PrP knockout animals, it provokes cerebellar ataxia. As this phenotype is rescued by reintroducing the PrP gene, it has been suggested that Doppel and PrP^c have antagonistic functions and may compete for a common ligand. However, a direct interaction between the two proteins has recently been observed.

To investigate whether the neuronal environment is suitable for such possibility, human Doppel and PrP^c were expressed separately, or together, in neuroblastoma cells, and then studied by biochemical and immunomicroscopic tools, as well as in intact cells expressing fluorescent fusion constructs.
The results demonstrate that Doppel and PrP^c co-patch extensively at the plasma membrane, and get internalized together after ganglioside cross-linking by cholera toxin or addition of an antibody against only one of the proteins. These processes no longer occur if the integrity of rafts is disrupted. We also show that, whereas each protein expressed alone occupies Triton X-100-insoluble membrane microdomains, co-transfected Doppel and PrP^c redistribute together into a less ordered lipidic environment. All these features are consistent with interactions occurring between Doppel and PrP^c in our neuronal cell model.

3.520 Synaptotagmins are trafficked to distinct subcellular domains including the postsynaptic compartment
Adolfsen, B., Sarawati, S., Yoshihara, M. and Littleton, J.T.
J. Cell Biol., ***166(2)***, *249-260 (2004)*

The synaptotagmin family has been implicated in calcium-dependent neurotransmitter release, although Synaptotagmin 1 is the only isoform demonstrated to control synaptic vesicle fusion. Here, we report the characterization of the six remaining synaptotagmin isoforms encoded in the *Drosophila* genome, including homologues of mammalian Synaptotagmins 4, 7, 12, and 14. Like Synaptotagmin 1, Synaptotagmin 4 is ubiquitously present at synapses, but localizes to the postsynaptic compartment. The remaining isoforms were not found at synapses (Synaptotagmin 7), expressed at very low levels (Synaptotagmins 12 and 14), or in subsets of putative neurosecretory cells (Synaptotagmins α and ß). Consistent with their distinct localizations, overexpression of Synaptotagmin 4 or 7 cannot functionally substitute for the loss of Synaptotagmin 1 in synaptic transmission. Our results indicate that synaptotagmins are differentially distributed to unique subcellular compartments. In addition, the identification of a postsynaptic synaptotagmin suggests calcium-dependent membrane-trafficking functions on both sides of the synapse.

3.521 *Drosophila* Wnt-1 undergoes a hydrophobic modification and is targeted to lipid rafts, a process that requires porcupine
Zhai, L., Chaturvedi, D. and Cumberledge, S.
J. Biol. Chem., ***279(32)***, *33220-33227 (2004)*

Wnt signaling pathways regulate many developmental responses; however, little is known about how Wnt ligands function on a biochemical level. Recent studies have shown that Wnt-3a is palmitoylated before secretion. Here we report that *Drosophila* Wnt-1 (Wingless) also undergoes a lipid modification. Lipidation occurs in the endoplasmic reticulum and is dependent on Porcupine, a putative *O*-acyltransferase. After modification, DWnt-1 partitions as a membrane-anchored protein and is sorted into lipid raft detergent-insoluble microdomains. Lipidation, raft targeting, and secretion can be blocked by the addition of 2-bromopalmitate, a competitive inhibitor of *O*-acyltransferase activity. Based on these results we propose a model whereby lipidation targets Wnt-1 to secretory vesicles that deliver the ligand to specialized microdomains at the cell surface where it can be packaged for secretion.

3.522 Oligomerization of the sensory and motor neuron-derived factor prevents protein O-glycosylation
Cabedo, H., Carteron, C. and Ferrer-Montiel, A.
J. Biol. Chem., ***279(32)***, *33623-33629 (2004)*

The sensory and motor neuron-derived factor (SMDF) is a neuregulin that promotes Schwann cell proliferation and differentiation. Hence, understanding axon myelination is important to unveil the mechanisms involved in SMDF biogenesis, membrane delivery, and compartmentalization. SMDF is a type II membrane protein expressed as two distinct polypeptides of ~40 and 83 kDa. Whether the 83-kDa polypeptide results from posttranslational modifications of the protein monomers or protein dimerization remains unknown. Here we have addressed this question and shown that the 83-kDa polypeptide is an *O*-glycosylated form of the protein. Deletion of the N-terminal domain fully abrogates the SMDF *O*-glycosylation, indicating that incorporation of *O*-glycans occurs in the intracellular domain of the protein. Notably, *O*-glycosylated forms are excluded from partitioning into lipid raft microdomains. In addition, we found that heterologously expressed SMDF monomers interact in intact living cells as evidenced from fluorescence resonance energy transfer of cyan fluorescent protein/yellow fluorescent protein·SMDF

fusion proteins. A stepwise deletion approach demonstrated that SMDF self-association is primarily determined by its transmembrane segment. Notably, biochemical analysis revealed that SMDF multimers are exclusively composed of the 40-kDa polypeptide. Collectively, these findings indicate that the 40-kDa form corresponds to unmodified SMDF, which may be present as multimers, whereas the 83-kDa polypeptide is a monomeric *O*-glycosylated form of the protein. Furthermore, our observations imply a role for oligomerization as a potential modulator of the distribution in membrane domains and *O*-glycosylation of the protein.

3.523 Differential signaling pathways are activated in the Epstein-Barr virus-activated malignancies nasopharyngeal carcinoma and Hodgkin lymphoma
Morrison, J.A., Gulley, M.L., Pathmanathan, R. and Raab-Traub, N.
*Cancer. Res.,**64**, 5251-5260 (2004)*

EBV is associated with the epithelial cancer, nasopharyngeal carcinoma (NPC), and the lymphoid malignancy, Hodgkin lymphoma (HL). The EBV latent membrane proteins 1 and 2A are expressed in these tumors. These proteins activate the phosphatidylinositol 3'-OH kinase (PI3K)/Akt pathway, which is commonly activated inappropriately in malignancy. In this study, the status of Akt activation and its targets, glycogen synthase kinase-3ß (GSK-3ß) and ß-catenin, was investigated in NPC and HL clinical specimens. In the majority of HL and NPC specimens, Akt was activated, indicating an important role for this kinase in the development and/or progression of these tumors. Akt phosphorylates and inactivates GSK-3ß, a negative regulator of the proto-oncoprotein ß-catenin that is aberrantly activated in many cancers. GSK-3ß was phosphorylated and inactivated with concomitant nuclear ß-catenin accumulation in the majority of NPC specimens. The malignant cells of the majority of HL cases, however, did not have inactivated GSK-3ß and lacked nuclear ß-catenin expression. These data indicate that this signaling arm of PI3K/Akt is universal and important in NPC pathogenesis but is apparently not affected in HL. These findings point to a divergence in pathways activated by EBV in different cellular contexts.

3.524 Comparisons of physical separation methods of Kunjin virus-induced membranes
Kim, M., Mackenzie, J.M. and Westaway, E.G.
*J. Virol. Meth., **120**, 179-187 (2004)*

two sets of connected membranes induced in Kunjin virus-infected cells are characterized by the presence of NS3 helicase/protease in both, and by RNA-dependent RNA polymerase (RdRp) activity plus the associated double-stranded RNA (dsRNA) template in vesicle packets (VP), or by the absence of both the VP-specific markers in the convoluted membranes/paracrystalline arrays (CM/PC). Attempts were made to separate flavivirus-induced membranes by sedimentation or flotation analyses in density gradients of sucrose or **iodixanol,** respectively, after treatment of cell lysates by sonication, osmotic shock, or tryptic digestion. Only osmotic shock treatment provided suggestive evidence of separation. This was explored by flow cytometry analysis (FCA) of RdRp active membrane fractions from a sucrose gradient, using dual fluorescent labelling via antibodies to NS3 and dsRNA. FCA revealed the presence of a dual labelled membrane population indicative of VP, and in a faster sedimenting fraction a membrane population able to be labelled only in NS3, representative of CM/PC and associated (R)ER. It was postulated that osmotic shock ruptured the bounding membrane of the VP, releasing the enclosed small vesicles associated with the Kunjin virus replication complex characterized previously. Notably, the presence of the full spectrum of nonstructural proteins in some membrane fractions was not a reliable marker for RdRp activity. These experiments may provide the opportunity for isolation of relatively pure flavivirus replication complexes in their native membrane-associated state by fluorescence-activated cell sorting.

3.525 Membrane dynamics in giant unilamminar vesicles (GUVS) of raft and non-raft fractions of brushborders membranes
Cheng, M. et al
Biophysical Meeting 2004 abstract

Lipid rafts are discrete regions in the plasma membrane which are composed of lipids that exist in the liquid ordered state, and are believed to function as platforms for protein and lipid transport. These structures are reported to be present in numerous membrane systems, including brushborder membranes in kidney cells. This research aims to study the membrane dynamics in brushborder membranes and membrane fractions of rat renal proximal tubular cells. Fluorescence (Laurdan) provided direct visualization of GUVs formed through electroformation of raft and non-raft fractions of intact renal brushborder membranes. Flotation through a density gradient (Optiprep) separated the raft and non-raft

fractions without the use of a detergent. Two-photon scanning microscopy of the GUVs formed from the raft fraction showed uniform fluorescence intensity images with some non-fluorescent domains of a few microns in size. Previous GUV studies of raft fractions obtained through detergent extraction yielded vesicles devoid of domains. Membrane fluidity measured as Laurdan Generalized Polarization (GP) function was monitored across a physiological temperature range (25°-42°C) in the GUVs. The GP in the raft fraction indicated a less fluid phase than in the non-raft fraction. This result is consistent with the compositional differences in these membrane fractions, particularly in terms of sphingomyelin and cholesterol content. Scanning fluctuation correlation spectroscopy performed on the intact brushborder membrane revealed the diffusion rate of NaPi-II cotransporter, a brushborder membrane specific protein, to be consistent with the mobility of a membrane associated protein.

3.526 Phagosome microdomains define foci of specialized functions in innate immunity
Goyette, G. et al
ICI/FOCIS 2004 meeting abstract no. 2246 (2004)

Macrophages are cells of the immune system specialized in the destruction of invading pathogens, and the elaboration of an efficient immune response. Phagocytosis, the process by which pathogens are internalized by host cells, leads to the formation of phagosomes at the cell surface by the direct recruitment of the endoplasmic reticulum. Phagosomes engage in a complex maturation process leading to the formation of phagolysosomes, allowing the killing and degradation of microorganisms. Unfortunately, several microorganisms have evolved strategies to alter phagolysosome biogenesis, a process still poorly understood. Proteomics analyses revealed that phagosomes are made of hundreds of proteins, highlighting the complexity of the molecular mechanisms involved in phagosome functions. We have shown recently that the phagosome membrane is not homogeneous but rather made of microdomains. The functions of these cholesterol-enriched microdomains on phagosomes are unknown. To understand these functions, we initiated the systematic characterization of these domains using a proteomics approach. Phagosome microdomains were isolated based on their insolubility in Triton X-100 and their flotation on Optiprep™ step gradients. MS/MS analyses of these microdomains led to the identification of 264 proteins indicating that functions such as acidification, cholesterol metabolism, signal transduction, and membrane fusion are likely to take place on phagosome membrane microdomains.
Results also indicate that the intracellular pathogen *Leishmania donovani* survives in macrophages by using a surface glycolipid to disrupt the proper organization of phagosome lipid rafts, highlighting the potential involvement of these structures in our ability to fight infection.

3.527 Linking receptor-mediated endocytosis and cell signaling
Zou, Z. et al
J. Biol. Chem., ***279(33)***, *34302-34310 (2004)*

Megalin, a member of the low density lipoprotein receptor gene family, is required for efficient protein absorption in the proximal tubule. Recent studies have shown that the low density lipoprotein receptor-related protein, another member of this gene family, is proteolytically processed by γ-secretase implying a role for low density lipoprotein receptor-related protein in a Notchlike signaling pathway. This pathway has been shown to involve: 1) metalloprotease-mediated ectodomain shedding and γ-secretase-mediated intramembrane proteolysis of some receptors. Experiments were performed to determine whether megalin undergoes similar processing. By immunocytochemistry, immunoblotting, and a fluorogenic enzyme assay presenilin-1 (required for γ-secretase activity) and γ-secretase activity were found in the brush border of proximal kidney tubules where megalin is localized. Using a fluorogenic peptide containing an amyloid precursor protein γ-secretase cleavage site and Compound E, a specific γ-secretase inhibitor, we found high levels of γ-secretase activity in renal brush border membrane vesicles. Immunoblotting analysis of renal microsomes and opossum kidney proximal tubule (OKP) cells using antibodies directed to the cytosolic domain of megalin showed a 35–40-kDa, membrane-associated, carboxyl-terminal fragment of megalin (MCTF). When cells were incubated with 200 nM phorbol 12-myristate 13-acetate, the appearance of the MCTF increased 2.5-fold and was blocked by metalloprotease inhibitors. When the cells were incubated with γ-secretase inhibitor Compound E, it caused a 2-fold increase in MCTF. Finally, incubating the cells with 1 μM vitamin D-binding protein resulted in a 25% increase in the appearance of the MCTF. In summary, the MCTF is produced by protein kinase C regulated, metalloprotease-mediated ectodomain shedding and is the substrate for γ-secretase. We postulate that the enzymatic processing of megalin represents part of a novel ligand-dependent signaling pathway in the proximal tubule that links receptor-mediated endocytosis with cell signaling.

3.528 Bph1p, the *Saccharomyces cerevisiae* homologue of CHS1/beige, functions in cell wall formation and protein sorting

Shiffert, S.L., Vaughn, M.B., Huynh, D., Kaplan, J. and McVey Ward, D.
*Traffic, **5**, 700-710 (2004)*

Mutations in the Chediak-Higashi syndrome gene (*CHS1*) and its murine homologue *Beige* result in the formation of enlarged lysosomes. *BPH1* (Beige Protein Homologue 1) encodes the *Saccharomyces cerevisiae* homologue of CHS1/Beige. *BPH1* is not essential and the encoded protein was found to be both cytosolic and peripherally bound to a membrane. Neither disruption nor overexpression of *BPH1* affected vacuole morphology as assessed by fluorescence microscopy. The δ*bph1* strain showed an impaired growth on defined synthetic media containing potassium acetate buffered below pH 4.25, increased sensitivity to calcofluor white, and increased agglutination in response to low pH. A library screen identified *VPS9*, *FLO1*, *FLO9*, *BTS1* and *OKP1* as high copy suppressors of the growth defect of δ*bph1* on both low pH potassium acetate and calcofluor white. The δ*bph1* strain demonstrated a mild defect in sorting vacuolar components, including increased secretion of carboxypeptidase Y and missorting of alkaline phosphatase. Overexpression of *VPS9*, *BTS1* and *OKP1* suppressed the carboxypeptidase Y secretion defect of δ*bph1*. Overexpression of *BPH1* was found to suppress the calcofluor white sensitivity of a class E *VPS* deletion strain, δ*vta1*. Together, these data suggest that Bph1p associates with a membrane and is involved in protein sorting and cell wall formation.

3.529 Nicalin and its binding partner Nomo are novel Nodal aignaling antagonists

Haffner, C. et al

Nodals are signaling factors of the transforming growth factor-ß (TGFß) superfamily with a key role in vertebrate development. They control a variety of cell fate decisions required for the establishment of the embryonic body plan. We have identified two highly conserved transmembrane proteins, Nicalin and Nomo (Nodal modulator, previously known as pM5), as novel antagonists of Nodal signaling. Nicalin is distantly related to Nicastrin, a component of the Alzheimer's disease-associated γ-secretase, and forms a complex with Nomo. Ectopic expression of both proteins in zebrafish embryos causes cyclopia, a phenotype that can arise from a defect in mesendoderm patterning mediated by the Nodal signaling pathway. Accordingly, downregulation of Nomo resulted in an increase in anterior axial mesendoderm and the development of an enlarged hatching gland. Inhibition of Nodal signaling by ectopic expression of Lefty was rescued by reducing Nomo levels. Furthermore, Nodal- as well as Activin-induced signaling was inhibited by Nicalin and Nomo in a cell-based reporter assay. Our data demonstrate that the Nicalin/Nomo complex antagonizes Nodal signaling during mesendodermal patterning in zebrafish.

3.530 Cell surface ceramide generation precedes and controls FcγRII clustering and phosphorylation in rafts

Shakor, A.B.A., Kwiatkowska, K. and Sobota, A.
*J. Biol. Chem., **279(35)**, 36778-36787 (2004)*

Despite the role of sphingolipid/cholesterol rafts as signaling platforms for Fcγ receptor II (FcγRII), the mechanism governing translocation of an activated receptor toward the rafts is unknown. We show that at the onset of FcγRII cross-linking acid sphingomyelinase is rapidly activated. This enzyme is extruded from intracellular compartments to the cell surface, and concomitantly, exofacially oriented ceramide is produced. Both non-raft and, to a lesser extent, raft sphingomyelin pools were hydrolyzed at the onset of FcγRII cross-linking. The time course of ceramide production preceded the recruitment of FcγRII to rafts and the receptor phosphorylation. Exogenous C_{16}-ceramide facilitated clustering of FcγRII and its association with rafts. In contrast, inhibition of acid sphingomyelinase diminished both the ceramide generation and clustering of cross-linked FcγRII. Under these conditions, tyrosine phosphorylation of FcγRII and receptor-accompanying proteins was also reduced. All the inhibitory effects were bypassed by treatment of cells with exogenous ceramide. These data provide evidence that the generation of cell surface ceramide is a prerequisite for fusion of cross-linked FcγRII and rafts, which triggers the receptor tyrosine phosphorylation and signaling.

3.531 Neu4, a novel human lysosomal lumen sialidase, confers normal phenotype to sialidosis and galactosialidosis cells

Seyrantepe, V. et al
*J. Biol. Chem., **279(35)**, 37021-37029 (2004)*

Three different mammalian sialidases have been described as follows: lysosomal (Neu1, gene *NEU1*), cytoplasmic (Neu2, gene *NEU2*), and plasma membrane (Neu3, gene *NEU3*). Because of mutations in the *NEU1* gene, the inherited deficiency of Neu1 in humans causes the severe multisystemic neurodegenerative disorder sialidosis. Galactosialidosis, a clinically similar disorder, is caused by the secondary Neu1 deficiency because of genetic defects in cathepsin A that form a complex with Neu1 and activate it. In this study we describe a novel lysosomal lumen sialidase encoded by the *NEU4* gene on human chromosome 2. We demonstrate that Neu4 is ubiquitously expressed in human tissues and has broad substrate specificity by being active against sialylated oligosaccharides, glycoproteins, and gangliosides. In contrast to Neu1, Neu4 is targeted to lysosomes by the mannose 6-phospate receptor and does not require association with other proteins for enzymatic activity. Expression of Neu4 in the cells of sialidosis and galactosialidosis patients results in clearance of storage materials from lysosomes suggesting that Neu4 may be useful for developing new therapies for these conditions.

3.532 Atg21 is required for effective recruitment of Atg8 to the preautophagosomal structure during the Cvt pathway
Meiling-Wesse, K. et al
J. Biol. Chem., ***279(36)***, *37741-37759 (2004)*

Atg21 and Atg18 are homologue yeast proteins. Whereas Atg18 is essential for the Cvt pathway and autophagy, a lack of Atg21 only blocks the Cvt pathway. Our proteinase protection experiments now demonstrate that growing *atg21*Δ cells fail to form proaminopeptidase I-containing Cvt vesicles. Quantitative measurement of autophagy in starving *atg21*Δ cells showed only 35% of the wild-type rate. This suggests that Atg21 plays a nonessential role in improving the fidelity of autophagy. The intracellular localization of Atg21 is unique among the Atg proteins. In cells containing multiple vacuoles, Atg21-yellow fluorescent protein clearly localizes to the vertices of the vacuole junctions. Cells with a single vacuole show most of the protein at few perivacuolar punctae. This distribution pattern is reminiscent to the Vps class C(HOPS) (homotypic fusion and vacuolar protein sorting) protein complex. In growing cells, Atg21 is required for effective recruitment of Atg8 to the preautophagosomal structure. Consistently, the covalent linkage of Atg8 to the lipid phosphatidylethanolamine is significantly retarded. Lipidated Atg8 is supposed to act during the elongation of autophagosome precursors. However, despite the reduced autophagic rate and the retardation of Atg8 lipidation, electron microscopy of starved *atg21*Δ *ypt7*Δ double mutant cells demonstrates the formation of normally sized autophagosomes with an average diameter of 450 nm.

3.533 Interactions of EGFR and caveolin-1 in human glioblastoma cells: evidence that tyrosine phosphorylation regulates EGFR association with caveolae
Abulrob, A. et al
Oncogene, ***23****, 6967-6979 (2004)*

Epidermal growth factor receptor (EGFR) amplification and type III mutation (EGFRvIII), associated with constitutive tyrosine kinase activation and high malignancy, are commonly observed in glioblastoma tumors. The association of EGFR and EGFRvIII with caveolins was investigated in human glioblastoma cell lines, U87MG and U87MG-EGFRvIII. Caveolin-1 expression, determined by RT–PCR, real-time quantitative PCR and Western blot, was upregulated in glioblastoma cell lines (two-fold) and tumors (20–300-fold) compared to primary human astrocytes and nonmalignant brain tissue, respectively. U87MG-EGFRvIII expressed higher levels of caveolin-1 than U87MG. In contrast, the expression of caveolin-2 and -3 were downregulated in glioblastoma cells compared to astrocytes. A colocalization of EGFR, but not of EGFRvIII, with lipid rafts and caveolin-1 was observed by immunocytochemistry. Association of EGFR and EGFRvIII with caveolae, assessed *in vitro* by binding to caveolin scaffolding domain peptides and *in vivo* by immunocolocalization studies in cells and caveolae-enriched cellular fraction, was phosphorylation-dependent: ligand-induced phosphorylation of EGFR resulted in dissociation of EGFR from caveolae. In contrast, inhibition of the EGFRvIII constitutive tyrosine phosphorylation by AG1478 increased association of EGFRvIII with caveolin-1. AG1478 also increased caveolin-1 expression and reduced glioblastoma cell growth in a semi-solid agar. The evidence suggests that the phosphorylation-regulated sequestration of EGFR in caveolae may be involved in arresting constitutive or ligand-induced signaling through EGFR responsible for glial cell transformation.

3.534 Isolated plant nuclei as mechanical and thermal sensors involved in calcium signaling
Xiong, T.C., Jauneau, A., Ranjeva, R. and Mazars, C.
The Plant J., ***40****, 12-21 (2004)*

Calcium signals in the nucleus elicit downstream effects that are distinct from those of cytosolic calcium signals. In the present work, we have evaluated the ability of plant nuclei to sense stimuli directly and to convert them into calcium changes. We show that individual mechanical stimulation of isolated nuclei elicits a single calcium transient at acidic pHs, whereas a series of stimulations leads to oscillations whose frequency reflects that of the stimuli. Conversely, at alkaline pHs, nuclei respond to temperature but not to stretch. The stretch- and the temperature-activated processes differ by their sensitivity to pharmacological drugs known to affect ion channel activities in animal cells. Our data demonstrate that isolated nuclei are able to gauge physical parameters of their environment. This might have a profound influence on the functioning of calcium-dependent processes known to control a large array of molecular events in the nucleus.

3.535 CLIPR-59 is a lipid raft-associated protein containing a cytoskeleton-associated protein glycine-rich domain (CAP-Gly) that perturbs microtubule dynamics
Lallamand-Breitenbach, V. et al
J. Biol. Chem., ***279(39)***, *41168-41178 (2004)*

We recently have identified a new cytoplasmic linker protein (CLIP), CLIPR-59, which is involved in the regulation of early endosome/*trans*-Golgi network dynamics. In contrast with CLIP-170, CLIPR-59 is not localized to microtubules at steady state but is associated with the *trans*-Golgi network and the plasma membrane. Here we show that the last 30 amino acids (C30) are sufficient for membrane targeting and that two cysteines in the C30 domain are palmitoylated. We demonstrate that CLIPR-59 is associated with lipid rafts via its C-terminal palmitoylated domain. *In vitro* experiments suggest that CLIPR-59 and its microtubule-binding domain alone have a better affinity for unpolymerized tubulin or small oligomers than for microtubules. In contrast with the CLIP-170 microtubule-binding domain, the CLIPR-59 microtubule-binding domain diminishes microtubule regrowth after nocodazole washout *in vivo*, showing that this domain can prevent microtubule polymerization. In contrast with the role of linker between membranes and microtubules that was proposed for CLIP function, CLIPR-59 thus may have an "anti-CLIP" function by preventing microtubule-raft interactions.

3.536 Reorganization of lipid rafts during capacitation of human sperm
Cross, N.L.
Biol. Reprod., ***71***, *1367-1373 (2004)*

Ejaculated mammalian sperm must complete a final maturation, termed capacitation, before they can undergo acrosomal exocytosis and fertilize an egg. In human sperm, loss of sperm sterol is an obligatory, early event in capacitation. How sterol loss leads to acrosomal responsiveness is unknown. These experiments tested the hypothesis that loss of sperm sterol affects the organization of cold detergent-resistant membrane microdomains (lipid "rafts"). The GPI-linked protein CD59, the ganglioside GM1, and the protein flotillin-2 were used as markers for lipid rafts. In uncapacitated sperm, 51% of the CD59, 41% of the GM1, and 90% of the flotillin-2 were found in the raft fraction. During capacitation, sperm lost 67% of their 3ß-hydroxysterols, and the percentages of CD59 and GM1 in the raft fraction decreased to 34% and 31%, respectively. The distribution of flotillin-2 did not change. Preventing a net loss of sperm sterol prevented the loss of CD59 and GM1 from the raft fraction. Fluorescence microscopy showed CD59 and GM1 to be distributed over the entire sperm surface. Flotillin-2 was located mainly in the posterior head and midpiece. Patching using bivalent antibodies indicated that little of the GM1 and CD59 was stably associated in the same membrane rafts. Likewise, GM1 and flotillin-2 were not associated in the same membrane rafts. In summary, lipid rafts of heterogeneous composition were identified in human sperm and the two raft components, GM1 and CD59, showed a partial sterol loss-dependent shift to the nonraft domain during capacitation.

3.537 An N-terminal amphipathic helix in hepatitis C virus (HCV) NS4B mediates membrane association, correct localization of replication complex proteins, and RNA replication
Elazar, M., Liu, P., Rice, C.M. and Glenn, J.S.
J. Virol., ***78(20)***, *11393-11400 (2004)*

Like other positive-strand RNA viruses, hepatitis C virus (HCV) is believed to replicate its RNA in association with host cell cytoplasmic membranes. Because of its association with such membranes, NS4B, one of the virus's nonstructural proteins, may play an important role in this process, although the mechanistic details are not well understood. We identified a putative N-terminal amphipathic helix (AH) in

NS4B that mediates membrane association. Introduction of site-directed mutations designed to disrupt the hydrophobic face of the AH abolishes the AH's ability to mediate membrane association. An AH in NS4B is conserved across HCV isolates. Completely disrupting the amphipathic nature of NS4B's N-terminal helix abolished HCV RNA replication, whereas partial disruption resulted in an intermediate level of replication. Finally, immunofluorescence studies revealed that HCV replication complex components were mislocalized in the AH-disrupted mutant. These results identify a key membrane-targeting domain which can form the basis for developing novel antiviral strategies.

3.538 Functional similarity between the peroxisomal PTS2 receptor binding protein Pex18p and the N-terminal half of the PTS1 receptor Pex5p
Schäfer, A., Kerssen, D., Veenhuis, M., Kunau, W-H. And Schliebs, W.
*Mol. Cell Biol., **24(20)**, 8895-8906 (2004)*

Within the extended receptor cycle of peroxisomal matrix import, the function of the import receptor Pex5p comprises cargo recognition and transport. While the C-terminal half (Pex5p-C) is responsible for PTS1 binding, the contribution of the N-terminal half of Pex5p (Pex5p-N) to the receptor cycle has been less clear. Here we demonstrate, using different techniques, that in *Saccharomyces cerevisiae* Pex5p-N alone facilitates the import of the major matrix protein Fox1p. This finding suggests that Pex5p-N is sufficient for receptor docking and cargo transport into peroxisomes. Moreover, we found that Pex5p-N can be functionally replaced by Pex18p, one of two auxiliary proteins of the PTS2 import pathway. A chimeric protein consisting of Pex18p (without its Pex7p binding site) fused to Pex5p-C is able to partially restore PTS1 protein import in a *PEX5* deletion strain. On the basis of these results, we propose that the auxiliary proteins of the PTS2 import pathway fulfill roles similar to those of the N-terminal half of Pex5p in the PTS1 import pathway.

3.539 BZLF1, an Epstein-Barr virus immediate-early protein, induces p65 nuclear translocation while inhibiting p65 transcriptional function
Morrison, T.E. and Kenncy, S.C.
*Virology, **328**, 219-232 (2004)*

We have previously demonstrated that the Epstein–Barr virus immediate–early BZLF1 protein interacts with, and is inhibited by, the NF-κB family member p65. However, the effects of BZLF1 on NF-κB activity have not been intensively studied. Here we show that BZLF1 inhibits p65-dependent gene expression. BZLF1 inhibited the ability of IL-1, as well as transfected p65, to activate the expression of two different NF-κB-responsive genes, ICAM-1 and IκB-α. BZLF1 also reduced the constitutive level of IκB-α protein in HeLa and A549 cells, and increased the amount of nuclear NF-κB to a similar extent as tumor necrosis factor-alpha (TNF-α) treatment. In spite of this BZLF1-associated increase in the nuclear form of NF-κB, BZLF1 did not induce binding of NF-κB to NF-κB responsive promoters (as determined by chromatin immunoprecipitation assay) in vivo, although TNF-α treatment induced NF-κB binding as expected. Overexpression of p65 dramatically inhibited the lytic replication cycle of EBV in 293-EBV cells, confirming that NF-κB also inhibits BZLF1 transcriptional function. Our results are consistent with a model in which BZLF1 inhibits the transcriptional function of p65, resulting in decreased transcription of IκB-α, decreased expression of IκB-α protein, and subsequent translocation of NF-κB to the nucleus. This nuclear translocation of NF-κB may promote viral latency by negatively regulating BZLF1 transcriptional activity. In situations where p65 activity is limiting in comparison to BZLF1, the ability of BZLF1 to inhibit p65 transcriptional function may protect the virus from the host immune system during the lytic form of infection.

3.540 Targeting, import, and dimerization of a mammalian mitochondrial ATP binding cassette (ABC) transporter, ABCB10 (ABC-me)
Graf, S.A., Haigh, S.E., Corson, E.D. and Shirihai, O.S.
*J. Biol. Chem., **279(41)**, 42954-42963 (2004)*

ATP binding cassette (ABC) transporters are a diverse superfamily of energy-dependent membrane translocases. Although responsible for the majority of transmembrane transport in bacteria, they are relatively uncommon in eukaryotic mitochondria. Organellar trafficking and import, in addition to quaternary structure assembly, of mitochondrial ABC transporters is poorly understood and may offer explanations for the paucity of their diversity. Here we examine these processes in ABCB10 (ABC-me), a

mitochondrial inner membrane erythroid transporter involved in heme biosynthesis. We report that ABCB10 possesses an unusually long 105-amino acid mitochondrial targeting presequence (mTP). The central subdomain of the mTP (amino acids (aa) 36–70) is sufficient for mitochondrial import of enhanced green fluorescent protein. The N-terminal subdomain (aa 1–35) of the mTP, although not necessary for the trafficking of ABCB10 to mitochondria, participates in the proper import of the molecule into the inner membrane. We performed a series of amino acid mutations aimed at changing specific properties of the mTP. The mTP requires neither arginine residues nor predictable α-helices for efficient mitochondrial targeting. Disruption of its hydrophobic character by the mutation L46Q/I47Q, however, greatly diminishes its efficacy. This mutation can be rescued by cryptic downstream (aa 106–715) mitochondrial targeting signals, highlighting the redundancy of this protein's targeting qualities. Mass spectrometry analysis of chemically cross-linked, immunoprecipitated ABCB10 indicates that ABCB10 embedded in the mitochondrial inner membrane homodimerizes and homo-oligomerizes. A deletion mutant of ABCB10 that lacks its mTP efficiently targets to the endoplasmic reticulum. Quaternary structure assembly of ABCB10 in the ER appears to be similar to that in the mitochondria.

3.541 Differential compartmentalization of the calpain/calpastatin network with the endoplasmic reticulum and Golgi apparatus
Hood, J.L., Brooks, W.H. and Roszman, T.L.
J. Biol. Chem., ***279(41)****, 43126-43135 (2004)*

Calpain, a calcium-activated cysteine protease, is involved in modulating a variety of cell activities such as shape change, mobility, and apoptosis. The two ubiquitous isoforms of this protease, calpain I and II, are considered to be cytosolic proteins that can translocate to various sites in the cell. The activity of calpain is modulated by two regulatory proteins, calpastatin, the specific endogenous inhibitor of calpain, and the 28-kDa regulatory subunit. Using velocity gradient centrifugation, the results of this study confirm and greatly expand upon our previous finding that the calpain/calpastatin network is associated with the endoplasmic reticulum and Golgi apparatus in cells. Moreover, confocal microscopy demonstrates that calpain II colocalizes with specific proteins found in these organelles. Additional experiments reveal that hydrophobic rather than electrostatic interactions are responsible for the association of the calpain/calpastatin network with these organelles. Treatment of the organelles with Na_2CO_3 or deoxycholate reveal that calpain I, 78-kDa calpain II, and the regulatory subunit are "embedded" within the organelle membranes similar to integral membrane proteins. Proteinase K treatment of the organelles shows that calpain I and II, calpastatin, and the regulatory subunit localize to the cytosolic surface of the organelle membranes, and a subset of calpain II and the regulatory subunit are also found within the lumen of these organelles. These results provide a new and novel explanation for how the calpain/calpastatin network is organized in the cell.

3.542 Hepatitis C virus core protein associates with detergent-resistant membranes distinct from classical plasma membrane rafts
Matto, M., Rice, C.M., Aroeti, B. and Glenn, J.S.
J. Virol., ***78(21)****, 12047-12053 (2004)*

A subpopulation of hepatitis C virus (HCV) core protein in cells harboring full-length HCV replicons is biochemically associated with detergent-resistant membranes (DRMs) in a manner similar to that of markers of classical lipid rafts. Core protein does not, however, colocalize in immunofluorescence studies with classical plasma membrane raft markers, such as caveolin-1 and the B subunit of cholera toxin, suggesting that core protein is bound to cytoplasmic raft microdomains distinct from caveolin-based rafts. Furthermore, while both the structural core protein and the nonstructural protein NS5A associate with membranes, they do not colocalize in the DRMs. Finally, the ability of core protein to localize to the DRMs did not require other elements of the HCV polyprotein. These results may have broad implications for the HCV life cycle and suggest that the HCV core may be a valuable probe for host cell biology.

3.543 Dynamic confinement of NK2 receptors in the plasma membrane
Cezanne, L. et al
J. Biol. Chem., ***279(43)****, 45057-45067 (2004)*

A functional fluorescent neurokinin NK2 receptor, EGFP-NK2, was previously used to follow, by fluorescence resonance energy transfer measurements in living cells, the binding of its fluorescently labeled agonist, bodipy-neurokinin A (NKA). Local agonist application suggested that the activation and desensitization of the NK2 receptors were compartmentalized at the level of the plasma membrane. In this

study, fluorescence recovery after photobleaching experiments are carried out at variable observation radius (vrFRAP) to probe EGFP-NK2 receptor mobility and confinement. Experiments are carried out at 20 °C to maintain the number of receptors constant at the cell surface during recordings. In the absence of agonist, 35% EGFP-NK2 receptors diffuse within domains of 420 ± 80 nm in radius with the remaining 65% of receptors able to diffuse with a long range lateral diffusion coefficient between the domains. When cells are incubated with a saturating concentration of NKA, 30% EGFP-NK2 receptors become immobilized in small domains characterized by a radius equal to 170 ± 50 nm. Biochemical experiments show that the confinement of EGFP-NK2 receptor is not due to its association with rafts at any given time. Colocalization of the receptor with β-arrestin and transferrin supports that the small domains, containing 30% of activated EGFP-NK2, correspond to clathrin-coated pre-pits. The similar amount of confined EGFP-NK2 receptors found before and after activation (30–35%) is discussed in term of putative transient interactions of the receptors with preexisting scaffolds of signaling molecules.

3.544 ATP-binding cassette (ABC) transporters mediate nonvesicular, raft-modulatd sterol movement from the plasma membrane to the endoplasmic reticulum
Li, Y and Priz, W.A.
J. Biol. Chem., ***279(43)***, *45226-45234 (2004)*

Little is known about the mechanisms of intracellular sterol transport or how cells maintain the high sterol concentration of the plasma membrane (PM). Here we demonstrate that two inducible ATP-binding cassette (ABC) transporters (Aus1p and Pdr11p) mediate nonvesicular movement of PM sterol to the endoplasmic reticulum (ER) in *Saccharomyces cerevisiae*. This transport facilitates exogenous sterol uptake, which we find requires steryl ester synthesis in the ER. Surprisingly, while expression of Aus1p and Pdr11p significantly increases sterol movement from PM to ER, it does not alter intracellular sterol distribution. Thus, ER sterol is likely rapidly returned to the PM when it is not esterified in the ER. We show that the propensity of PM sterols to be moved to the ER is largely determined by their affinity for sterol sphingolipid-enriched microdomains (rafts). Our findings suggest that raft association is a primary determinant of sterol accumulation in the PM and that Aus1p and Pdr11p facilitate sterol uptake by increasing the cycling of sterol between the PM and ER.

3.545 Participation of G protein in natriuretic peptide hormone secretion from heart atria
Bensimon, M. et al
Endocrinol., ***145***, *5313-5321 (2004)*

The involvement of G proteins in the mechanism underlying the increased atrial natriuretic factor (ANF) secretion observed after atrial muscle stretch (stretch-secretion coupling) was assessed using a combined pharmacological, immunocytochemical, and tissue fractionation approach. It was found that $G_{i/o}$ inhibition by pertussis toxin (PTX) abolished stretch-secretion coupling without affecting baseline secretion through a mechanism that is independent of G_q signaling agonists. Mastoparan-7, a $G_{i/o}$ agonist, significantly increased ANF secretion even in the absence of muscle stretch through a PTX-sensitive mechanism. By confocal and electron immunocytochemistry, ANF and G_o partially colocalized, whereas ultracentrifugation analysis suggested the presence of two populations of granules, one of which was partially associated with G_o, as demonstrated by Western blotting. PTX did not affect basal or endothelin-1-stimulated ANF secretion, in line with the view that endothelin-1 signals mainly through G_q. It is concluded there are at least two types of regulated secretory processes in atrial cardiocytes: one is acutely responsive to muscle stretch and is PTX sensitive, and the other is $G_q$mediated and PTX insensitive and may be responsible for changes in secretion after chronic changes in the neuroendocrine environment.

3.546 Real time analysis of intact organelle using surface plasmon resonance
Ferraci, G., Seagar, M., Joël, C., Miquelis, R. And Leveque, C.
Anal. Biochem., ***334***, *367-375(2004)*

Membrane proteins remain refractory to standard protein chip analysis. They are typically expressed at low densities in distinct subcellular compartments, their biological activity can depend on assembly into macromolecular complexes in a specific lipid environment. We report here a real-time, label-free method to analyze membrane proteins inserted in isolated native synaptic vesicles. Using surface plasmon resonance-based biomolecular interaction analysis (Biacore), organelle capture from minute quantities of 10,000*g* brain supernatant (1–10 μg) was monitored. Immunological and morphological characterization indicated that pure intact synaptic vesicles were immobilized on sensor chips. Vesicle chips were stable for days, allowing repetitive use with multiple analytes. This method provides an efficient way in which to

characterize organelle membrane components in their native context. Organelle chips allow a broad range of measurements, including interactions of exogenous ligands with the organelle surface (kinetics, K_d), and protein profiling.

3.547 The vitamin D receptor is present in caveolae-enriched plasma membranes and binds 1α,25(OH)$_2$-vitamin D$_3$ in vivo and in vitro

Huhtakangas, J.A., Olivera, C.J., Bishop, J.E., Zanello, L.P. and Norman, A.W.
Mol. Endocrinol., ***18(11)***, *2660-2671 (2004)*

The steroid hormone 1α,25(OH)$_2$-vitamin D$_3$ (1,25D) regulates gene transcription through a nuclear receptor [vitamin D receptor (VDR)] and initiation of rapid cellular responses through a putative plasma membrane-associated receptor (VDR$_{mem}$). This study characterized the VDR$_{mem}$ present in a caveolae-enriched membrane fraction (CMF), a site of accumulation of signal transduction agents. Saturable and specific [^{3}H]-1,25D binding *in vitro* was found in CMF of chick, rat, and mouse intestine; mouse lung and kidney; and human NB4 leukemia and rat ROS 17/2.8 osteoblast-like cells; in all cases the 1,25D K_D binding dissociation constant = 1–3 nM. Our data collectively support the classical VDR being the VDR$_{mem}$ in caveolae: 1) VDR antibody immunoreactivity was detected in CMF of all tissues tested; 2) competitive binding of [^{3}H]-1,25D by eight analogs of 1,25D was significantly correlated between nuclei and CMF (r^2 = 0.95) but not between vitamin D binding protein (has a different ligand binding specificity) and CMF; 3) confocal immunofluorescence microscopy of ROS 17/2.8 cells showed VDR in close association with the caveolae marker protein, caveolin-1, in the plasma membrane region; 4) *in vivo* 1,25D pretreatment reduced *in vitro* [^{3}H]-1,25D binding by 30% in chick and rat intestinal CMF demonstrating *in vivo* occupancy of the CMF receptor by 1,25D; and 5) comparison of [^{3}H]-1,25D binding in VDR KO and WT mouse kidney tissue showed 85% reduction in VDR KO CMF and 95% reduction in VDR KO nuclear fraction. This study supports the presence of VDR as the 1,25D-binding protein associated with plasma membrane caveolae.

3.548 Both the sequence and length of the C terminus of PEN-2 are critical for intermolecular interactions and function of presenilin complexes

Hasegawa, H. et al
J. Biol. Chem., ***279(45)***, *46455-46463 (2004)*

Presenilin 1 or presenilin 2, nicastrin, APH-1, and PEN-2 form high molecular weight complexes that play a pivotal role in the cleavage of various Type I transmembrane proteins, including the β-amyloid precursor protein. The specific function of PEN-2 is unclear. To explore its function and intermolecular interactions, we conducted deletion and mutagenesis studies on a series of conserved residues at the C terminus of PEN-2. These studies suggest that: 1) both the presence and amino acid sequence of the conserved DYLSF domain at the C terminus of PEN-2 (residues 90–94) is critical for binding PEN-2 to other components in the presenilin complex and 2) the overall length of the exposed C terminus is critical for functional γ-secretase activity.

3.549 The target cell plasma membrane is a critical interface for *Salmonella* cell entry effector-host interplay

Cain, R.J., Hayward, R.D. and Koronakis, V.
Mol. Microbiol., ***54(4)***, *887-904 (2004)*

Salmonella species trigger host membrane ruffling to force their internalization into non-phagocytic intestinal epithelial cells. This requires bacterial effector protein delivery into the target cell via a type III secretion system. Six translocated effectors manipulate cellular actin dynamics, but how their direct and indirect activities are spatially and temporally co-ordinated to promote productive cytoskeletal rearrangements remains essentially unexplored. To gain further insight into this process, we applied mechanical cell fractionation and immunofluorescence microscopy to systematically investigate the subcellular localization of epitope-tagged effectors in transiently transfected and *Salmonella*-infected cultured cells. Although five effectors contain no apparent membrane-targeting domains, all six localized exclusively in the target cell plasma membrane fraction and correspondingly were visualized at the cell periphery, from where they induced distinct effects on the actin cytoskeleton. Unexpectedly, no translocated effector pool was detectable in the cell cytosol. Using parallel *in vitro* assays, we demonstrate

that the prenylated cellular GTPase Cdc42 is necessary and sufficient for membrane association of the *Salmonella* GTP exchange factor and GTPase-activating protein mimics SopE and SptP, which have no intrinsic lipid affinity. The data show that the host plasma membrane is a critical interface for effector-target interaction, and establish versatile systems to further dissect effector interplay.

3.550 Segregation of Nogo66 receptors into lipid rafts in rat brain and inhibition of Nogo66 signaling by cholesterol depletion
Yu, W., Guo, W. and Feng, L.
*FEBS Lett., **577**, 87-92 (2004)*

NogoA, a myelin-associated component, inhibits neurite outgrowth. Nogo66, a portion of NogoA, binds to Nogo66 receptor (NgR) and induces the inhibitory signaling. LINGO-1 and p75 neurotrophin receptor (p75), the low-affinity nerve growth factor receptor, are also required for NogoA signaling. However, signaling mechanisms downstream to Nogo receptor remain poorly understood. Here, we observed that NgR and p75 were colocalized in low-density membrane raft fractions derived from forebrains and cerebella as well as from cerebellar granule cells. NgR interacted with p75 in lipid rafts. In addition, disruption of lipid rafts by β-methylcyclodextrin, a cholesterol-binding reagent, reduced the Nogo66 signaling. Our results suggest an important role of lipid rafts in facilitating the interaction between NgRs and provide insight into mechanisms underlying the inhibition of neurite outgrowth by NogoA.

3.551 The behavior of peroxisomes in vitro: mammalian peroxisomes are osmotically sensitive particles
Antonenko, V.D., Sormunen, R.T. and Hiltunen, J.K.
*Am. J. Physiol., **287**, C1623-C1635 (2004)*

It has been known for a long time that mammalian peroxisomes are extremely fragile in vitro. Changes in the morphological appearance and leakage of proteins from purified particles demonstrate that peroxisomes are damaged during isolation. However, some properties of purified peroxisomes, e.g., the latency of catalase, imply that their membranes are not disrupted. In the current study, we tried to ascertain the mechanism of this unusual behavior of peroxisomes in vitro. Biochemical and morphological examination of isolated peroxisomes subjected to sonication or to freezing and thawing showed that the membrane of the particles seals after disruption, restoring permeability properties. Transient damage of the membrane leads to the formation of peroxisomal "ghosts" containing nucleoid but nearly devoid of matrix proteins. The rate of leakage of matrix proteins from broken particles depended inversely on their molecular size. The effect of polyethylene glycols on peroxisomal integrity indicated that these particles are osmotically sensitive. Peroxisomes suffered an osmotic lysis during isolation that was resistant to commonly used low-molecular-mass osmoprotectors, e.g., sucrose. Damage to peroxisomes was partially prevented by applying more "bulky" osmoprotectors, e.g., polyethylene glycol 1500. A method was developed for the isolation of highly purified and nearly intact peroxisomes from rat liver by using polyethylene glycol 1500 as an osmoprotector.

3.552 A common mechanism for the regulation of vesicular SNAREs on phospholipid membranes
Hu, K., Rickman, C., Carroll. J. and Davletov, B.
*Biochem.J., **377**, 781-765 (2004)*

The SNARE (soluble *N*-ethylmaleimide-sensitive fusion protein attachment protein receptor) family of proteins is essential for membrane fusion in intracellular traffic in eukaryotic organisms. v-SNAREs (vesicular SNAREs) must engage target SNAREs in the opposing membrane to form the fusogenic SNARE complex. Temporal and spatial control of membrane fusion is important for many aspects of cell physiology and may involve the regulation of the SNAREs resident on intracellular membranes. Here we show that the v-SNARE synaptobrevin 2, also known as VAMP (vesicle-associated membrane protein) 2, is restricted from forming the SNARE complex in chromaffin granules from adrenal medullae to the same degree as in brain-purified synaptic vesicles. Our analysis indicates that the previously reported synaptophysin–synaptobrevin interaction is not likely to be involved in regulation of the v-SNARE. Indeed, the restriction can be reproduced for two distinct v-SNARE homologues, synaptobrevin 2 and cellubrevin/VAMP3, by reconstituting them in pure liposomal membranes. Overall, our data uncover a common mechanism for the control of SNARE engagement where intact phospholipid membranes rather than proteins down-regulate vesicular SNAREs in different cellular organelles.

3.553 Membrane and raft association of reggie-1/flotillin-2: role of myristoylation, palmitoylation and oligomerization and induction of filopodia by overexpression
Neumann-Giesen, C. Et al
*Biochem. J., **378**, 509-518 (2004)*

The reggie protein family consists of two proteins, reggie-1 and -2, also called flotillins, which are highly ubiquitous and evolutionarily conserved. Both reggies have been shown to be associated with membrane rafts and are involved in various cellular processes such as T-cell activation, phagocytosis and insulin signalling. However, the exact molecular function of these proteins remains to be determined. In addition, the mechanism of membrane association of reggie-1, which does not contain any transmembrane domain, is not known. In this study, we have produced a fusion protein of reggie-1 with enhanced green fluorescent protein and generated targeted substitutions for the inactivation of putative palmitoylation and myristoylation sites. We were able to show that reggie-1 is myristoylated and multiply palmitoylated and that lipid modifications are necessary for membrane association of reggie-1. Overexpression of reggie-1 resulted in the induction of numerous filopodia-like protrusions in various cell lines, suggesting a role for reggie-1 as a signalling protein in actin-dependent processes.

3.554 Different subcellular localization of sulphotransferase 2B1b in human placenta and prostate
He, D., Meloche, C.A., Dumas, N.A., Frost, A.R. and Falany, C.N.
*Biochem. J., **379**, 533-540 (2004)*

The human hydroxysteroid SULT (sulphotransferase) 2B1 subfamily consists of two isoforms, SULT2B1a and SULT2B1b. These two isoenzymes are transcribed from the same gene by alternative splicing of their first exons and share 94% amino acid sequence identity. The SULT2B1 isoforms are highly selective for the sulphation of 3β-hydroxysteroids. Immunoblot analysis of SULT2B1 expression in several human tissues indicates the presence of only SULT2B1b protein. Immunoreactive SULT2B1b protein was detected in human prostate, skin, placenta and lung tissue. SULT2B1b mRNA expression was detected in RNA isolated from term placenta, normal prostate, prostate carcinoma, benign prostate hyperplasia, LNCaP prostate cancer cells, breast cancer specimens and MCF-7 breast cancer cells. Immunohistochemical localization of SULT2B1b, in terms placental and prostate tissues, detected it in nuclei of placental syncytiotrophoblasts and cytoplasm of epithelial cells in prostate tissues. Immunoreactive and catalytically active SULT2B1b was identified in nuclei isolated from term human placenta. Also SULT2B1b was capable of translocating to nuclei in BeWo placental cells after stable transfection and differentiation. In contrast, immunohistochemical analysis of human prostate showed only cytosolic localization of SULT2B1b in the basal and luminal prostate epithelial cells. SULT2B1b was not detected in isolated nuclei from LNCaP prostate cancer cells but was present in the cytosolic fraction. Differential subcellular localization of SULT2B1b in prostate and placenta suggests that SULT2B1b may be differentially regulated and have different physiological functions in these two hormonally responsive human tissues.

3.555 Recruitment of the cross-linked opsonic receptor CD32A (FcγRIIA) to high density detergent-resistant membrane domains in human neutrophils
Rollet-Labelle, E., Marois, S., Barbeau, K., Malawista, S.E. and Naccache, P.H.
*Biochem. J., **381**, 919-928 (2004)*

We have previously shown that CD32A (or FcγRIIA), one of the main opsonin receptors, was rapidly insolubilized and degraded in intact neutrophils after its cross-linking. In view of these experimental difficulties, the early signalling steps in response to CD32A activation were studied in purified plasma membranes of neutrophils. After CD32A cross-linking in these fractions, the tyrosine phosphorylation of two major substrates, the receptor itself and the tyrosine kinase Syk, was observed. Phosphorylation of these two proteins was observed only in the presence of orthovanadate, indicating the presence, in the membranes, of one or more tyrosine phosphatases that maintain CD32A dephosphorylation. The tyrosine phosphorylation of these two proteins was inhibited by the Src kinase inhibitor, 4-amino-5-(4-chlorophenyl)-7-(t-butyl)pyrazolo[3,4-*d*]pyrimidine (PP2). The ligation of CD32A led to its recruitment to a previously uncharacterized subset of high-density flotillin-1-positive DRMs (detergent-resistant membranes). The changes in the solubility properties of CD32A were observed in the absence of added ATP; therefore, they were probably not secondary to the tyrosine phosphorylation of the receptor, rather they preceded it. Src kinases as well as Syk were constitutively present in DRMs of high and low density and no evident changes in their distribution were detected after cross-linking of CD32A. Pretreatment of

plasma membranes with methyl-β-cyclodextrin did not inhibit the recruitment of CD32A to DRMs, although it led to the loss of the Src kinase Lyn from these fractions. In addition, methyl-β-cyclodextrin inhibited the tyrosine phosphorylation of CD32A and Syk induced by cross-linking of CD32A. This membrane model allowed us to observe a movement of CD32A from detergent-soluble regions of the membranes to DRMs, where it joined Src kinases and Syk and became tyrosine-phosphorylated.

3.556 Structure and cholesterol domain dynamics of an enriched caveolae/raft isolate
Gallegos, A.M., McIntosh, A.L., Atshaves, B.P. and Schroeder, F.
*Biochem. J., **382**, 451-461 (2004)*

Despite the importance of cholesterol in the formation and function of caveolar microdomains in plasma membranes, almost nothing is known regarding the structural properties, cholesterol dynamics or intracellular factors affecting caveolar cholesterol dynamics. A non-detergent method was employed to isolate caveolae/raft domains from purified plasma membranes of murine fibroblasts. A series of fluorescent lipid probe molecules or a fluorescent cholesterol analogue, dehydroergosterol, were then incorporated into the caveolae/raft domains to show that: (i) fluorescence polarization of the multiple probe molecules {diphenylhexatriene analogues, DiI_{18} (1,1´-dioctadecyl-3,3,3´,3´-tetramethylindocarbocyanine perchlorate), parinaric acids and NBD-stearic acid {12-(*N*-methyl)-*N*-[(7-nitrobenz-2-oxa-1,3-diazol-4-yl)amino]-octadecanoic acid} indicated that acyl chains in caveolae/raft domains were significantly less 'fluid' (i.e. more rigid) and the transbilayer 'fluidity gradient' was 4.4-fold greater than in plasma membranes; (ii) although sterol was more ordered in caveolae/raft domains than plasma membranes, spontaneous sterol transfer from caveolae/raft domains was faster (initial rate, 32%; half-time, $t_{1/2}$, 57%) than from the plasma membrane; (iii) although kinetic analysis showed similar proportions of exchangeable and non-exchangeable sterol pools in caveolae/raft domains and plasma membranes, addition of SCP-2 (sterol carrier protein-2) 1.3-fold more selectively increased sterol transfer from caveolae/raft domains by decreasing the $t_{1/2}$ (50%) and increasing the initial rate (5-fold); (iv) SCP-2 was also 2-fold more selective in decreasing the amount of non-exchangeable sterol in caveolae/raft domains compared with plasma membranes, such that nearly 80% of caveolar/raft sterol became exchangeable. In summary, although caveolae/raft lipids were less fluid than those of plasma membranes, sterol domains in caveolae/rafts were more spontaneously exchangeable and more affected by SCP-2 than those of the bulk plasma membranes. Thus caveolae/raft domains isolated without the use of detergents display unique structure, cholesterol domain kinetics and responsiveness to SCP-2 as compared with the parent plasma membrane.

3.557 Rafts can trigger contact-mediated secretion of bacterial effectors via a lipid-based mechanism
Van der Goot, F.G., Tran van Nhieu, G., Allaoui, A., Sansonetti, P and Lafont, F.
*J. Biol. Chem., **279(46)**, 47792-47798 (2004)*

Infection by the Gram-negative bacterial pathogen *Shigella flexneri* depends on its ability to invade host cells. Bacterial engulfment requires a functional type III secretion system (TTSS) allowing the translocation into host cells of bacterial effectors that activate cell-signaling cascades. We demonstrated previously that specialized lipid membrane domains enriched in cholesterol and sphingolipids (rafts) are involved during early steps of invasion, namely in binding and host cell entry. In this study, we addressed the issue of contact-mediated secretion by the TTSS. We show that contact-mediated and TTSS-induced hemolysis depend on the presence of cholesterol on the host cell surface. We found that purified detergent resistant membranes were able to activate TTSS. Finally, we found that artificial liposomes, devoid of proteins, were able to activate the TTSS but only when their composition mimicked that of lipid rafts. Altogether, these data indicate that specific lipid packing can trigger contact-mediated secretion by *S. flexneri*.

3.558 Rhodopsin signaling and organization in heterozygote rhodosin knockout mice
Linag, Y. et al
*J. Biol. Chem., **279(46)**, 48189-48196 (2004)*

Rhodopsin (Rho) resides within internal membrane structures called disc membranes that are found in the rod outer segments (ROS) of photoreceptors in the retina. Rho expression is essential for formation of ROS, which are absent in knockout Rho-/- mice. ROS of mice heterozygous for the *Rho* gene deletion (Rho+/-) may have a lower Rho density than wild type (WT) membranes, or the ROS structure may be reduced in size due to lower Rho expression. Here, we present evidence that the smaller volume of ROS from heterozygous mice is most likely responsible for observed electrophysiological response differences. In

Rho+/- mice as compared with age-matched WT mice, the length of ROS was shorter by 30–40%, and the average diameter of ROS was reduced by ~20%, as demonstrated by transmission and scanning electron microscopy. Together, the reduction of the volume of ROS was ~60% in Rho+/- mice. Rho content in the eyes was reduced by ~43% and 11-*cis*-retinal content in the eye was reduced by ~38%, as determined by UV-visible spectroscopy and retinoid analysis, respectively. Transmission electron microscopy of negatively stained disc membranes from Rho+/- mice indicated a typical morphology apart from the reduced size of disc diameter. Power spectra calculated from disc membrane regions on such electron micrographs displayed a diffuse ring at ~4.5 nm^{-1}, indicating paracrystallinity of Rho. Atomic force microscopy of WT and Rho+/- disc membranes revealed, in both cases, Rho organized in paracrystalline and raftlike structures. From these data, we conclude that the differences in physiological responses measured in WT and Rho+/- mice are due to structural changes of the whole ROS and not due to a lower density of Rho.

3.559 Oligomerization triggers binding of a *Bacillus thuringiensis* Cry1Ab pore-forming toxin to aminopeptidase N receptor leading to insertion into membrane microdomains
Bravo, A. et al
*Biochim. Biophys. Acta, **1667**, 38-46 (2004)*

Bacillus thuringiensis Cry1A toxins, in contrast to other pore-forming toxins, bind two putative receptor molecules, aminopeptidase N (APN) and cadherin-like proteins. Here we show that Cry1Ab toxin binding to these two receptors depends on the toxins' oligomeric structure. Toxin monomeric structure binds to Bt-R_1, a cadherin-like protein, that induces proteolytic processing and oligomerization of the toxin (Gómez, I., Sánchez, J., Miranda, R., Bravo A., Soberón, M., FEBS Lett. (2002) 513, 242–246), while the oligomeric structure binds APN, which drives the toxin into the detergent-resistant membrane (DRM) microdomains causing pore formation. Cleavage of APN by phospholipase C prevented the location of Cry1Ab oligomer and Bt-R_1 in the DRM microdomains and also attenuates toxin insertion into membranes despite the presence of Bt-R_1. Immunoprecipitation experiments demonstrated that initial Cry1Ab toxin binding to Bt-R_1 is followed by binding to APN. Also, immunoprecipitation of Cry1Ab toxin-binding proteins using pure oligomeric or monomeric structures showed that APN was more efficiently detected in samples immunoprecipitated with the oligomeric structure, while Bt-R_1 was preferentially detected in samples immunoprecipitated with the monomeric Cry1Ab. These data agrees with the 200-fold higher apparent affinity of the oligomer than that of the monomer to an APN enriched protein extract. Our data suggest that the two receptors interact sequentially with different structural species of the toxin leading to its efficient membrane insertion.

3.560 Fas ligand is enriched in the caveolae membrane domains of thymic epithelial cells
Lalor, D., Liu, P. and Hayashi, J.
*Cellular Immunol., **230**, 10-16 (2004)*

Both Fas and Fas ligand (FasL) are expressed in the thymus. Although reports suggest that they are important throughout the thymocyte maturation process their precise role remains elusive. The present paper characterizes the expression of FasL in the thymus and in the TEA3A1 and BT1B functional thymic epithelial cell (TEC) lines. FasL expression by thymus fractions, TEA3A1, and BT1B cells was detected by Northern blot analysis. In TEA3A1 cells, we discovered that FasL protein expression was localized to caveolae membrane domains. This restricted subcellular localization of FasL, together with reports describing the localization of the major histocompatibility complex proteins, the T cell receptor and Fas to caveolae membrane domains, may provide a mechanism for the deletion of thymocytes during negative selection. Finally, using semi-quantitative RT-PCR we found that FasL expression by TECs is regulated by glucocorticoids.

3.561 Partitioning of NAP_i cotransporter in cholesterol-, sphingonyelin-, and glycophingolipid-enriched membrane domains modulates NAP_i protein diffusion, clustering, and activity
Inoue, M. et al
*J. Biol. Chem., **279(47)**, 49160-49171 (2004)*

In dietary potassium deficiency there is a decrease in the transport activity of the type IIa sodium/phosphate cotransporter protein (NaP_i) despite an increase in its apical membrane abundance. This novel posttranslational regulation of NaP_i activity is mediated by the increased glycosphingolipid content of the potassium-deficient apical membrane. However, the mechanisms by which these lipids modulate NaP_i activity have not been determined. We determined if in potassium deficiency NaP_i is increasingly

partitioned in cholesterol-, sphingomyelin-, and glycosphingolipid-enriched microdomains of the apical membrane and if the increased presence of NaP_i in these microdomains modulates its activity. By using a detergent-free density gradient flotation technique, we found that 80% of the apical membrane NaP_i partitions into the low density cholesterol-, sphingomyelin-, and GM1-enriched fractions characterized as "lipid raft" fractions. In potassium deficiency, a higher proportion of NaP_i was localized in the lipid raft fractions. By combining fluorescence correlation spectroscopy and photon counting histogram methods for control and potassium-deficient apical membranes reconstituted into giant unilamellar vesicles, we showed a 2-fold *decrease* in lateral diffusion of NaP_i protein and a greater than 2-fold *increase* in size of protein aggregates/clusters in potassium deficiency. Our results indicate that NaP_i protein is localized in membrane microdomains, that in potassium deficiency a larger proportion of NaP_i protein is present in these microdomains, and that NaP_i lateral diffusion is slowed down and NaP_i aggregation/clustering is increased in potassium deficiency, both of which could be associated with the decreased Na/P_i cotransport activity in potassium deficiency.

3.562 Nef associates with p21-activated kinase 2 in a p21-GTPase-dependent dynamic activation complex within lipid rafts

Pulkkinen, K., Renkema, G.H., Kirchhoff, F. And Saksela, K.
J. Virol., ***78(23)***, *12773-12780 (2004)*

We have previously reported that Nef specifically interacts with a small but highly active subpopulation of p21-activated kinase 2 (PAK2). Here we show that this is due to a transient association of Nef with a PAK2 activation complex within a detergent-insoluble membrane compartment containing the lipid raft marker GM1. The low abundance of this Nef-associated kinase (NAK) complex was found to be due to an autoregulatory mechanism. Although activation of PAK2 was required for assembly of the NAK complex, catalytic activity of PAK2 also promoted dissociation of this complex. Testing different constitutively active PAK2 mutants indicated that the conformation associated with p21-mediated activation rather than kinase activity per se was required for PAK2 to become NAK. Although association with PAK2 is one of the most conserved properties of Nef, we found that the ability to stimulate PAK2 activity differed markedly among divergent Nef alleles, suggesting that PAK2 association and activation are distinct functions of Nef. However, mutations introduced into the p21-binding domain of PAK2 revealed that p21-GTPases are involved in both of these Nef functions and, in addition to promoting PAK2 activation, also help to physically stabilize the NAK complex.

3.563 Identification of Epstein-Barr virus RK-BARF0-interacting proteins and characterization of expression pattern

Thornburg, N.J., Kusano, S. and Raab-Traub, N.
J. Virol., ***78(23)***, *12848-12856 (2004)*

The Epstein-Barr virus (EBV) BamHI A transcripts are a family of transcripts that are differentially spliced and can be detected in multiple EBV-associated malignancies. Several of the transcripts may encode proteins. One transcript of interest, *RK-BARF0*, is proposed to encode a 279-amino-acid protein with a possible endoplasmic reticulum-targeting sequence. In this study, the properties of RK-BARF0 were examined through identification of cellular-interacting proteins through yeast two-hybrid analysis and characterization of its expression in EBV-infected cells and tumors. In addition to the interaction previously identified with cellular Notch, it was determined that RK-BARF0 also bound cellular human I-mfa domain-containing protein (HIC), epithelin, and scramblase. An interaction between RK-BARF0 and Notch or epithelin induced proteasome-dependent degradation of Notch and epithelin but not of HIC or scramblase. Low levels of endogenous Notch expression in EBV-positive cell lines may correlate with RK-BARF0 expression. However, a screen of EBV-positive cell lines and tumors with an affinity-purified α-RK-BARF0 antiserum did not consistently detect RK-BARF0. These data suggest that while RK-BARF0 may have important cellular functions during EBV infection, and while the phenotype of EBV-positive cells suggest its expression, RK-BARF0 levels may be too low to detect.

3.564 A mammalian ortholog of *Saccharomyces cerevisiae* Vac14 that associates with and Up-regulates PIKfyve phosphoinositide 5-kinase activity

Sbrissa, D. et al
Mol. Cell Biol., ***24(23)***, *10437-10447 (2004)*

Multivesicular body morphology and size are controlled in part by PtdIns(3,5)P_2, produced in mammalian cells by PIKfyve-directed phosphorylation of PtdIns(3)P. Here we identify human Vac14 (hVac14), an evolutionarily conserved protein, present in all eukaryotes but studied principally in yeast thus far, as a novel positive regulator of PIKfyve enzymatic activity. In mammalian cells and tissues, Vac14 is a low-abundance 82-kDa protein, but its endogenous levels could be up-regulated upon ectopic expression of hVac14. PIKfyve and hVac14 largely cofractionated, populated similar intracellular locales, and physically associated. A small-interfering RNA-directed gene-silencing approach to selectively eliminate endogenous hVac14 rendered HEK293 cells susceptible to morphological alterations similar to those observed upon expression of PIKfyve mutants deficient in PtdIns(3,5)P_2 production. Largely decreased in vitro PIKfyve kinase activity and unaltered PIKfyve protein levels were detected under these conditions. Conversely, ectopic expression of hVac14 increased the intrinsic PIKfyve lipid kinase activity. Concordantly, intracellular PtdIns(3)P-to-PtdIns(3,5)P_2 conversion was perturbed by hVac14 depletion and was elevated upon ectopic expression of hVac14. These data demonstrate a major role of the PIKfyve-associated hVac14 protein in activating PIKfyve and thereby regulating PtdIns(3,5)P_2 synthesis and endomembrane homeostasis in mammalian cells.

3.565 Localization of organelle proteins by isotope tagging (LOPIT)
Dunkley, T.P.J., Watson, R., Griffin, J.L., Dupree, P. and Liley, K.S.
*Mol. Cell. Proteomics, **3**, 1128-1134 (2004)*

We describe a proteomics method for determining the subcellular localization of membrane proteins. Organelles are partially separated using centrifugation through self-generating density gradients. Proteins from each organelle co-fractionate and therefore exhibit similar distributions in the gradient. Protein distributions can be determined through a series of pair-wise comparisons of gradient fractions, using cleavable ICAT to enable relative quantitation of protein levels by MS. The localization of novel proteins is determined using multivariate data analysis techniques to match their distributions to those of proteins that are known to reside in specific organelles. Using this approach, we have simultaneously demonstrated the localization of membrane proteins in both the endoplasmic reticulum and the Golgi apparatus in *Arabidopsis*. Localization of organelle proteins by isotope tagging is a new tool for high-throughput protein localization, which is applicable to a wide range of research areas such as the study of organelle function and protein trafficking.

3.566 Modulation of cyclin D1 and early growth response factor-1 gene expression in interleukin-1β-treated rat smooth muscle cells by n-6 and n-3 polyunsaturated fatty acids
Bousserouel, S., Raymondjean, M., Brouillet, A., Bereziat, G. and Andreani, M.
*Eur. J. Biochem., **271**, 4462-4473 (2004)*

The proliferation of smooth muscle cells (SMC) is a key event in the development of atherosclerosis. In addition to growth factors or cytokines, we have shown previously that n-3 polyunsaturated fatty acids (PUFAs) act in opposition to n-6 PUFAs by modulating various steps of the inflammatory process. We have investigated the molecular mechanisms by which the incorporation of the n-6 PUFA, arachidonic acid, increases the proliferation of rat SMC treated with interleukin-1β, while the n-3 PUFAs eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), elicit no mitogenic response. Incorporation of EPA or DHA into SMC, which are then activated by interleukin-1β to mimic inflammation, decreases promoter activity of the cyclin D1 gene and phosphorylation of the retinoblastoma protein. Together, our data demonstrate that n-3 effects are dependent on the Ras/Raf-1/extracellular signal regulated kinase (ERK)/mitogen-activated protein kinase pathway, and that down-regulation of the cyclin D1 promoter activity is mediated by the specific binding of the early growth response factor-1. Finally, we have shown that the incorporation of EPA and DHA also increased the concentration of caveolin-1 and caveolin-3 in caveolae, which correlated with n-3 PUFA inhibition of SMC proliferation through the mitogen-activated protein kinase pathway. We provide evidence indicating that, in contrast to n-6 PUFAs, n-3 PUFAs exert antiproliferative effects on SMC through the mitogen-activated protein kinase/ERK pathway.

3.567 Distribution of Can1p into stable domains reflects lateral protein segregation within the plasma membrane of living *S. cerevisiae* cells
Malinska, K., Malinsky, J., Opekarova, M. And Tanner, W.
*J. Cell Sci., **117**, 6031-6041 (2004)*

Recently, lipid-raft-based subdomains within the plasma membrane of living *Saccharomyces cerevisiae* cells were visualized using green fluorescent protein fusions, and non-overlapping subdomains containing either Pma1p or Can1p were distinguished. In this study, the long-term stability of the subdomains was investigated. Experiments with latrunculin A and nocodazole ruled out the involvement of cytoskeletal components in the stabilization of the subdomains. Also a putative role of the cell wall was excluded, because protoplasting of the cells changed neither the pattern nor the stability of the subdomains. By contrast, the expected inner dynamics of the membrane subdomains was documented by FRAP experiments. Finally, two other proteins were localized within the frame of the Can1p/Pma1p plasma-membrane partition. We show that Fur4p (another H^+ symporter) and Sur7p (a protein of unknown function) occupy the Can1p subdomain.

3.568 The H^+ -pyrophosphatase of *Rhodospirillum rubrun* is predominantly located in polyphosphate-rich acidocalcisomes

Seufferheld, M., Lea, C.R., Vieira, M., Oldfiled, E. and Docampo, R.
J. Biol. Chem., ***279(49)***, *51193-51202 (2004)*

Acidocalcisomes are acidic, calcium storage compartments with a H^+ pump located in their membrane that have been described in several unicellular eukaryotes, including trypanosomatid and apicomplexan parasites, algae, and slime molds, and have also been found in the bacterium *Agrobacterium tumefaciens.* In this work, we report that the H^+-pyrophosphatase (H^+-PPase) of *Rhodospirillum rubrum*, the first enzyme of this type that was identified and thought to be localized only to chromatophore membranes, is predominantly located in acidocalcisomes. The identification of the acidocalcisomes of *R. rubrum* was carried out by using transmission electron microscopy, x-ray microanalysis, and immunofluorescence microscopy. Purification of acidocalcisomes using iodixanol gradients indicated co-localization of the H^+-PPase with pyrophosphate (PP_i) and short and long chain polyphosphates (polyPs) but a lack of markers of the plasma membrane. polyP was also localized to the acidocalcisomes by using 4',6'-diamino-2-phenylindole staining and identified by using ^{31}P NMR and biochemical methods. Calcium in the acidocalcisomes increased when the bacteria were incubated at high extracellular calcium concentrations. The number of acidocalcisomes and chromatophore membranes as well as the amounts of PP_i and polyP increased when bacteria were grown in the light. Taken together, these results suggest that the H^+-PPase of *R. rubrum* has two distinct roles depending on its location acting as an intracellular proton pump in acidocalcisomes but in PP_i synthesis in the chromatophore membranes.

3.569 Bovine caveolin-2 cloning and effects of shear stress on its localization in bovine aortic endothelial cells

Boyd, N.L. et al
Endothelium, ***11****, 189-198 (2004)*

Caveolae are plasmalemmal domains enriched with cholesterol, caveolins, and signaling molecules. Normally, cells that express caveolin-1 also express caveolin-2, but this has not been demonstrated in bovine aortic endothelial cells (BAECs). Here, we show that BAECs express caveolin-2, which localizes in caveolae with caveolin-1. We have cloned the bovine caveolin-2 gene and after comparison with known protein sequences (human, murine, rat, and canine) have found divergent immunogenic regions (amino acid [aa] 21 to aa 50 and aa 79 to 88), which may explain the inability to detect caveolin-2 in different cell types. We developed a bovine caveolin-2–specific antibody to examine this protein's expression and localization in BAECs. We used differential gradient centrifugations and immunoprecipitation to show that bovine caveolin-2 and caveolin-1 form a hetero-oligomer in plasma membrane caveolae. Using immunocytochemistry we show that a pool of caveolin-2 also colocalizes with the cis-Golgi in static culture, but unlike caveolin-1, this Golgi associated pool is maintained after 1 day of shear exposure. Therefore, the interaction of caveolin-2 with caveolin-1 could play an important role in caveolae biogenesis and shear stimulated mechano-signal transduction.

3.570 Plasmin deficiency in Alzheimer's disease brains: causal or casual?

Dotti, C.G., Galvan, C. And Ledesma, M.D.
Neurodegenerative Dis., ***1****, 205-212 (2004)*

Substantial recent evidence suggests that defects in amyloid peptide degradation can be at the base of cases of sporadic Alzheimer's disease (AD). Among the discovered brain enzymes with the capacity to degrade amyloid peptide, the serine protease plasmin acquires special physiological relevance because of its low levels in areas of AD human brains with a high susceptibility to amyloid plaque accumulation. In this

article we comment on a series of observations supporting the fact that plasmin paucity in the brain is not simply a secondary event in the disease but rather a primary defect in certain cases of sporadic AD. We also refer to recent data pointing to alterations in raft membrane domains and diminished membrane cholesterol as the underlying cause. Finally, we discuss the possibility that plasmin deficiency in the brain could lead to AD symptomatology because of amyloid aggregation and the triggering of cell death signaling cascades.

3.571 **Leaky β-oxidation of a *trans* –fatty acid**
Yu, W. et al
J. Biol. Chem., ***279(50)***, *52160-52167 (2004)*

The degradation of elaidic acid (9-*trans*-octadecenoic acid), oleic acid, and stearic acid by rat mitochondria was studied to determine whether the presence of a *trans* double bond in place of a *cis* double bond or no double bond affects β-oxidation. Rat mitochondria from liver or heart effectively degraded the coenzyme A derivatives of all three fatty acids. However, with elaidoyl-CoA as a substrate, a major metabolite accumulated in the mitochondrial matrix. This metabolite was isolated and identified as 5-*trans*-tetradecenoyl-CoA. In contrast, little or none of the corresponding metabolites were detected with oleoyl-CoA or stearoyl-CoA as substrates. A kinetic study of long-chain acyl-CoA dehydrogenase (LCAD) and very long-chain acyl-CoA dehydrogenase revealed that 5-*trans*-tetradecenoyl-CoA is a poorer substrate of LCAD than is 5-*cis*-tetradecenoyl-CoA, while both unsaturated acyl-CoAs are poor substrates of very long-chain acyl-CoA dehydrogenase when compared with myristoyl-CoA. Tetradecenoic acid and tetradecenoylcarnitine were detected by gas chromatography/mass spectrometry and tandem mass spectrometry, respectively, when rat liver mitochondria were incubated with elaidoyl-CoA but not when oleoyl-CoA was the substrate. These observations support the conclusion that 5-*trans*-tetradecenoyl-CoA accumulates in the mitochondrial matrix, because it is less efficiently dehydrogenated by LCAD than is its *cis* isomer and that the accumulation of this β-oxidation intermediate facilitates its hydrolysis and conversion to 5-*trans*-tetradecenoylcarnitine thereby permitting a partially degraded fatty acid to escape from mitochondria. Analysis of this compromised but functional process provides insight into the operation of β-oxidation in intact mitochondria.

3.572 **Acidocalcisomes and the contractile vacuole complex are involved in osmoregulation in *Trypanosoma cruzi***
Rohloff, P., Montalvetti, A. and Docompo, R.
J. Biol. Chem., ***279(50)***, *52270-52281 (2004)*

Trypanosoma cruzi, the etiologic agent of Chagas disease, resists extreme fluctuations in osmolarity during its life cycle. *T. cruzi* possesses a robust regulatory volume decrease mechanism that completely reverses cell swelling when submitted to hypo-osmotic stress. The efflux of amino acids and K^+ release could account for only part for this volume reversal. In this work we demonstrate that swelling of acidocalcisomes mediated by an aquaporin and microtubule- and cyclic AMP-mediated fusion of acidocalcisomes to the contractile vacuole complex with translocation of this aquaporin and the resulting water movement are responsible for the volume reversal not accounted for by efflux of osmolytes. Contractile vacuole bladders were isolated by subcellular fractionation in **iodixanol** gradients, showed a high concentration of basic amino acids and inorganic phosphate, and were able to transport protons in the presence of ATP or pyrophosphate. Taken together, these results strongly support a role for acidocalcisomes and the contractile vacuole complex in osmoregulation and identify a functional role for aquaporin in protozoal osmoregulation.

3.573 **Intracellular processing and activation of membrane type 1 matrix metalloprotease depends on its partitioning into lipid domains**
Mazzone, M. et al
J. Cell Sci., ***117***, *6275-6287 (2004)*

The integral membrane type 1 matrix metalloprotease (MT1-MMP) is a pivotal protease in a number of physiological and pathological processes and confers both non-tumorigenic and tumorigenic cell lines with a specific growth advantage in a three-dimensional matrix. Here we show that, in a melanoma cell line, the majority (80%) of MT1-MMP is sorted to detergent-resistant membrane fractions; however, it is only the detergent-soluble fraction (20%) of MT1-MMP that undergoes intracellular processing to the mature form. Also, this processed MT1-MMP is the sole form responsible for ECM degradation in vitro. Finally, furin-

dependent processing of MT1-MMP is shown to occur intracellularly after exit from the Golgi apparatus and prior to its arrival at the plasma membrane. It is thus proposed that the association of MT1-MMP with different membrane subdomains might be crucial in the control of its different activities: for instance in cell migration and invasion and other less defined ones such as MT1-MMP-dependent signaling pathways.

3.574 Role of myosin VIIa and Rab27a in the motility and localization of RPE nelanosomes
Gibbs, D. Et al
*J. Cell Sci., **117**, 6473-6483 (2004)*

Myosin VIIa functions in the outer retina, and loss of this function causes human blindness in Usher syndrome type 1B (USH1B). In mice with mutant *Myo7a*, melanosomes in the retinal pigmented epithelium (RPE) are distributed abnormally. In this investigation we detected many proteins in RPE cells that could potentially participate in melanosome transport, but of those tested, only myosin VIIa and Rab27a were found to be required for normal distribution. Two other expressed proteins, melanophilin and myosin Va, both of which are required for normal melanosome distribution in melanocytes, were not required in RPE, despite the association of myosin Va with the RPE melanosome fraction. Both myosin VIIa and myosin Va were immunodetected broadly in sections of the RPE, overlapping with a region of apical filamentous actin. Some 70-80% of the myosin VIIa in RPE cells was detected on melanosome membranes by both subcellular fractionation of RPE cells and quantitative immunoelectron microscopy, consistent with a role for myosin VIIa in melanosome motility. Time-lapse microscopy of melanosomes in primary cultures of mouse RPE cells demonstrated that the melanosomes move in a saltatory manner, interrupting slow movements with short bursts of rapid movement (>1 μm/second). In RPE cells from *Myo7a*-null mice, both the slow and rapid movements still occurred, except that more melanosomes underwent rapid movements, and each movement extended approximately five times longer (and further). Hence, our studies demonstrate the presence of many potential effectors of melanosome motility and localization in the RPE, with a specific requirement for Rab27a and myosin VIIa, which function by transporting and constraining melanosomes within a region of filamentous actin. The presence of two distinct melanosome velocities in both control and *Myo7a*-null RPE cells suggests the involvement of at least two motors other than myosin VIIa in melanosome motility, most probably, a microtubule motor and myosin Va.

3.575 N-octyl-β-valienamine up-regulates activity of F213I mutant β-glucosidase in cultured cells: a potential chemical chaperone therapy for Gaucher disease
Lin, H. et al
*Biochim. Biophys. Acta, **1689**, 219-228 (2004)*

Gaucher disease (GD) is the most common form of sphingolipidosis and is caused by a defect of β-glucosidase (β-Glu). A carbohydrate mimic *N*-octyl-β-valienamine (NOV) is an inhibitor of β-Glu. When applied to cultured GD fibroblasts with F213I β-Glu mutation, NOV increased the protein level of the mutant enzyme and up-regulated cellular enzyme activity. The maximum effect of NOV was observed in F213I homozygous cells in which NOV treatment at 30 μM for 4 days caused a ~6-fold increase in the enzyme activity, up to ~80% of the activity in control cells. NOV was not effective in cells with other β-Glu mutations, N370S, L444P, 84CG and RecNciI. Immunofluorescence and cell fractionation showed localization of the F213I mutant enzyme in the lysosomes of NOV-treated cells. Consistent with this, NOV restored clearance of ^{14}C-labeled glucosylceramide in F213I homozygous cells. F213I mutant β-Glu rapidly lost its activity at neutral pH in vitro and this pH-dependent loss of activity was attenuated by NOV. These results suggest that NOV works as a chemical chaperone to accelerate transport and maturation of F213I mutant β-Glu and may suggest a therapeutic value of this compound for GD.

3.576 Overexpression of caveolin-1 increases plasma membrane fluidity and reduces P-glycoprotein function in Hs578T/Dox
Cai, C., Zhu, H. and Chen, J.
*Biochem. Biophys Res. Comm., **320**, 868-874 (2004)*

Cholesterol is a key lipid in mediating the enzyme activity or signaling pathway of many proteins on the plasma membrane in mammalian cells. In this report, we demonstrate for the first time that after overexpressing caveolin-1, the plasma membrane cholesterol level was decreased by about 12% and 30% for doxorubicin-sensitive and doxorubicin-resistant Hs578T breast cancer cells, respectively. However, the total cholesterol level in both cell lines was increased by about 10%. By measuring fluorescence and flow cytometry using the fluorescence dyes 1,6-diphenyl-1,3,5-hexatriene and Merocyanine 540, we found that

overexpressing caveolin-1 resulted in a similar increase in membrane fluidity and loosening of lipid packing density as cholesterol depletion by 1 mM methyl-β-cyclodextrin (MβCD) or 2-hydroxypropyl-β-cyclodextrin (HβCD). Moreover, we found that the transport activity of P-gp was significantly inhibited by 1 mM MβCD or HβCD, which is also similar to the inhibitory effect of caveolin-1 overexpression. Our data demonstrate for the first time that the reduction of the plasma membrane cholesterol level induced by overexpressing caveolin-1 may indirectly inhibit P-gp transport activity by increasing plasma membrane fluidity.

3.577 Depression of transcription and translation during daily torpor in the Djungarian hamster (*Phodopus sungorus)*
Diaz, M.B., Lange, M., Heldmaier, G. And Klingenspor, M.-
*J. Comp. Physiol. B, **174**, 495-502 (2004)*

During daily torpor, Djungarian hamsters reduce their metabolic rate by more than 70% below their resting metabolic rate for several hours per day. We investigated whether this depression of metabolism is associated with a reduction in transcription and translation. Liver tissue was sampled in defined metabolic states: during normometabolism, in the torpid state and after arousal from torpor. Nuclei were isolated from liver tissue and subjected to nuclear run-on assays at an assay temperature of 25 °C. We observed a ~40% decrease in transcriptional initiation in liver nuclei of hamsters which had attained minimal metabolic rate during torpor as compared to nuclei from normometabolic hamsters. During arousal from torpor, the transcriptional run-on activity recovered to the normometabolic level. Polysome profile analysis of liver tissue was used to determine the proportion of actively translating polysomes. Profiles of liver samples from torpid animals show a disaggregation of polysomes compared to profiles from normometabolic hamsters, which indicates that, in addition to transcription, protein synthesis decreases during torpor. These results indicate that during torpor a specific inhibition of the energetically costly processes of RNA and protein synthesis contributes to the overall metabolic depression.

3.578 Tyrosine phosphatase activity in mitochondria: presence of Shp-2 phosphatase in mitochondria
Salvi, M. Et al
*Cell. Mol. Life Sci., **61**, 2393-2404 (2004)*

Tyrosine phosphorylation by unidentified enzymes has been observed in mitochondria, with recent evidence indicating that non-receptorial tyrosine kinases belonging to the Src family, which represent key players in several transduction pathways, are constitutively present in mitochondria. The extent of protein phosphorylation reflects a coordination balance between the activities of specific kinases and phophatases. The present study demonstrates that purified rat brain mitochondria possess endogenous tyrosine phosphatase activity. Mitochondrial phosphatases were found to be capable of dephosphorylating different exogenous substrates, including paranitrophenylphosphate, ^{32}P-poly(Glu-Tyr)$_{4:1}$ and ^{32}P-angiotensin. These activities are strongly inhibited by peroxovanadate, a well-known inhibitor of tyrosine phosphatases, but not by inhibitors of alkali or Ser/Thr phosphatases, and mainly take place in the intermembrane space and outer mitochondrial membrane. Using a combination of approaches, we identified the tyrosine phosphatase Shp-2 in mitochondria. Shp-2 plays a crucial role in a number of intracellular signalling cascades and is probably involved in several human diseases. It thus represents the first tyrosine phosphatase shown to be present in mitochondria.

3.579 Paradoxical downregulation of the glucose oxidation pathway despite enhanced flux in severe heart failure
Lei, B. Et al
*J. Mol. Cell. Cardiol., **36**, 567-576 (2004)*

Free fatty acid (FFA) oxidation is depressed in severe heart failure due to reduced activity of mitochondrial fatty acid oxidation enzymes. It is unknown whether the concomitant enhancement in cardiac glucose use is a consequence of reduced FFA oxidation, or also due to potentiation of the carbohydrate oxidative pathway. FFA and glucose oxidation rates were measured *in vivo* in 9 normal dogs and 9 dogs with pacing-induced heart failure by infusing ^{3}H-oleate and ^{14}C-glucose. FFA oxidation was lower (39 ± 9 vs. 73 ± 5 nmol min^{-1} g^{-1}), while glucose oxidation was higher (42 ± 8 vs. 17 ± 6 nmol min^{-1} g^{-1}) in failing compared to normal hearts ($P < 0.05$). At the end of the *in vivo* experiment, clamp-frozen biopsies were harvested from the left ventricle. Messenger RNAs encoding for proteins involved in both glucose and fatty acid metabolism, and for citrate synthase, were significantly reduced. Protein expression of GLUT-1 and GLUT-4, and GLUT-4 translocation to the sarcolemma showed no significant differences between the

two groups despite a significant reduction in mRNAs with heart failure. GAPDH mRNA, protein expression, and activity were all reduced. The E2 subunit of pyruvate dehydrogenase was decreased both at the mRNA and protein level, with no effect on either fractional or maximal activity. In conclusion, we found either no changes or moderate downregulation of key enzymes of the carbohydrate metabolism in failing hearts, which suggests that the increase in glucose oxidation *in vivo* was principally due to impaired FFA oxidation and that the maximal myocardial capacity to obtain energy from substrate is globally depressed.

3.580 Acidocalsisomes of *Phytomonas francai* possess distinct morphological characteristics and contain iron

Miranda, K. et al
*Microsc. Microanal., **10**, 647-655 (2004)*

Acidocalcisomes are acidic calcium storage compartments described initially in trypanosomatid and apicomplexan parasites, and recently found in other unicellular eukaryotes. The aim of this study was to identify the presence of acidocalcisomes in the plant trypanosomatid Phytomonas francai. Electron-dense organelles of P. francai were shown to contain large amounts of oxygen, sodium, magnesium, phosphorus, potassium, calcium, iron, and zinc as determined by X-ray microanalysis, either in situ or when purified using iodixanol gradient centrifugation or by elemental mapping. The presence of iron is not common in other acidocalcisomes. In situ, but not when purified, these organelles showed an elongated shape differing from previously described acidocalcisomes. However, these organelles also possessed a vacuolar H+-pyrophosphatase (V-H+-PPase) as determined by biochemical methods and by immunofluorescence microscopy using antibodies against the enzyme. Together, these results suggest that the electron-dense organelles of P. francai are homologous to the acidocalcisomes described in other trypanosomatids, although with distinct morphology and elemental content.

3.581 Mechanisms of neurotrophin receptor vesicular transport

Yano, H. and Chao, M.V.
*J. Neurobiol**., **58**, 244-257 (2004)*

Accumulating evidence has indicated that neurotrophin receptor trafficking plays an important role in neurotrophin-mediated signaling in developing as well as mature neurons. However, little is known about the molecular mechanisms and the components of neurotrophin receptor vesicular transport. This article will describe how neurotrophin receptors, Trk and p75 neurotrophin receptor ($p75^{NTR}$), are intimately involved in the axonal transport process. In particular, the molecules that may direct Trk receptor trafficking in the axon will be discussed. Finally, potential mechanisms by which receptor-containing vesicles link to molecular cytoskeletal motors will be presented.

3.582 Effect of Membrane Perturbants on the Activity and Phase Distribution of Inositol Phosphorylceramide Synthase; Development of a Novel Assay

Aeed, P.A., Sperry, A.E., Young, C.L., Nagiec, M.M. andf Elhammer, Å.P.
*Biochemistry, **43**, 8483-8493 (2004)*

The effect of 26 different membrane-perturbing agents on the activity and phase distribution of inositol phosphorylceramide synthase (IPC synthase) activity in crude *Candida albicans* membranes was investigated. The nonionic detergents Triton X-100, Nonidet P-40, Brij, Tween, and octylglucoside all inactivated the enzyme. However, at moderate concentrations, the activity of the Triton X-100- and octylglucoside-solubilized material could be partially restored by inclusion of 5 mM phosphatidylinositol (PI) in the solubilization buffer. The apparent molecular mass of IPC synthase activity solubilized in 2% Triton X-100 was between 1.5×10^6 and 20×10^6 Da, while under identical conditions, octylglucoside-solubilized activity remained associated with large presumably membrane-like structures. Increased detergent concentrations produced more drastic losses of enzymatic activity. The zwitterionic detergents Empigen BB, *N*-dodecyl-*N*,*N*-(dimethylammonio)butyrate (DDMAB), Zwittergent 3-10, and amidosulfobetaine (ASB)-16 all appeared capable of solubilizing IPC synthase. However, these agents also inactivated the enzyme essentially irreversibly. Solubilization with lysophospholipids again resulted in drastic losses of enzymatic activity that were not restored by the inclusion of PI. Lysophosphatidylinositol also appeared to compete, to some extent, with the donor substrate phosphatidylinositol. The sterol-containing agent digitonin completely inactivated IPC synthase. By contrast, sterol-based detergents such as 3-[(3-cholamidopropyl)dimethylammonio]-1-propanesulfonate (CHAPS), 3-[(3-cholamidopropyl)dimethylammonio]-2-hydroxy-1-propanesulfonate (CHAPSO), and taurodeoxycholate

(tDOC) had little or no effect on the enzyme activity. The IPC synthase activity in *C. albicans* membranes remained largely intact and sedimentable at CHAPS concentrations (4%) where >90% of the phospholipids and 60% of the total proteins were extracted from the membranes. At 2.5% CHAPS, a concentration where approximately 50% of the protein and 80% of the phospholipids are solubilized, there was no detectable loss of enzyme activity, and it was found that the detergent-treated membranes had significantly improved properties compared to crude, untreated membranes as the source of IPC synthase activity. In contrast to assays utilizing intact membranes or Triton X-100 extracts, assays using CHAPS- or tDOC-washed membranes were found to be reproducible, completely dependent on added acceptor substrate (C_6-7-nitro-2-1,3-benzoxadiazol-4-yl (NBD)-ceramide), and >95% dependent on added donor substrate (PI). Product formation was linear with respect to both enzyme concentration and time, and transfer efficiency was improved more than 20-fold as compared to assays using crude membranes. Determination of kinetic parameters for the two IPC synthase substrates using CHAPS-washed membranes resulted in K_m values of 3.3 and 138.0 μM for C_6-NBD-ceramide and PI, respectively. In addition, the donor substrate, PI, was found to be inhibitory at high concentrations with an apparent K_i of 588.2 μM.

3.583

3.584 CD4-induced down-regulation of T cell adhesion to B cells is associated with localization of phosphatidyl inositol 3-kinase and LFA-1 in distinct membrane domains
Trucy, M., Barbat, C., Sorice, M., Fischer, A. and Mazerolles, F.
*Eur. J: Immunol., **34(8)**, 2168-2178 (2004)*

We have previously shown that binding of anti-CD4 antibody inhibit LFA-1-dependent adhesion between $CD4^+$ T cells and B cells in a $p56^{lck}$ and a PI3-kinase-dependent manner. In this work, we investigated with two different T cell lines (Jurkat and A201) whether CD4 binding could alter interactions of the proteins putatively involved in this adhesion regulatory pathway. Anti-CD4 binding was shown to induce a transient association between PI3-kinase and LFA-1, which took place in different regions of the plasma membrane. It was detected in detergent soluble membrane but also in detergent insoluble membrane consisting in raft microdomains, composed of GM1 and/or GM3 gangliosides. These results show that anti-CD4 Ab could modify the interaction between LFA-1 and signaling molecules, such as PI3-kinase and induce, in part, their recruitment in raft domains. By using specific inhibitors, raft integrity and CD4 association with GM3 were found necessary for observing the CD4-dependent inhibition of LFA-1-mediated adhesion. These results strongly suggest that these molecular rearrangements in the membrane are necessary to induce down-regulation of LFA-1-mediated adhesion.

3.585 Comparison of nerve terminal events in vivo effecting retrograde transport of vesicles containing neurotrophins or synaptic vesicle components
Weible II, M.W., Ozsarac, N., Grimes, M.L. and Hendry, I.A.
*J. Neurosci. Res., **75(6)**, 771-781 (2004)*

Although vesicular retrograde transport of neurotrophins in vivo is well established, relatively little is known about the mechanisms that underlie vesicle endocytosis and formation before transport. We demonstrate that in vivo not all retrograde transport vesicles are alike, nor are they all formed using identical mechanisms. As characterized by density, there are at least two populations of vesicles present in the synaptic terminal that are retrogradely transported along the axon: those containing neurotrophins (NTs) and those resulting from synaptic vesicle recycling. Vesicles containing nerve growth factor (NGF), NT-3, or NT-4 had similar densities with peak values at about 1.05 g/ml. Synaptic-derived vesicles, labeled with anti-dopamine β-hydroxylase (DBH), had densities with peak values at about 1.16 g/ml. We assayed the effects of pharmacologic agents in vivo on retrograde transport from the anterior eye chamber to the superior cervical ganglion. Inhibitors of phosphatidylinositol-3-OH (PI-3) kinase and actin function blocked transport of both anti-DBH and NGF, demonstrating an essential role for these molecules in retrograde transport of both vesicle types. Dynamin, a key element in synaptic vesicle recycling, was axonally transported in retrograde and anterograde directions, and compounds able to interfere with dynamin function had a differential effect on retrograde transport of NTs and anti-DBH. Okadaic acid significantly decreased retrograde axonal transport of anti-DBH and increased NGF retrograde transport. We conclude that there are both different and common proteins involved in endocytosis and targeting of retrograde transport of these two populations of vesicles.

3.586 Distinct protective mechanisms of HO-1 and HO-2 against hydroperoxide-induced cytotoxicity
Kim, Y-S., Zhuang, H., Koehler, R.C. and Dore, S.
*Free Radical Biology & Medicine, **38**, 85-92 (2005)*

Heme oxygenases (HO-1 and HO-2) catalyze the NADPH-cytochrome P_{450} reductase (CPR)-dependent degradation of heme into iron, carbon monoxide, and biliverdin, which is reduced into bilirubin. Under basal conditions, HO-1 is often undetected and can be induced by numerous stress conditions. Although HO-2 is constitutively expressed, its activity appears to be regulated by post-translational modifications. HO activity has been associated with cellular protection, by which it degrades heme, a prooxidant, into bioactive metabolites. Under given circumstances, overexpression of HO-1 can render cells more sensitive to free radicals. Here, we investigated the properties of human HO isoforms that protect against oxidative stress. Considering that CPR can be a limiting factor for optimal HO activity, we tested stable HO-1 and HO-2 cell lines that derived from the CPR cells. Results indicate that the HO-1 and HO-2 cells are more resistant than controls to hemin and to the organic *tert*-butyl hydroperoxide, *t*-BuOOH. However, HO-1 cells are less resistant than HO-2 cells to hydrogen peroxide (H_2O_2). The levels of oxidatively modified proteins of HO-1 and HO-2 cells in response to *t*-BuOOH toxicity are identical, but the level of oxidatively modified proteins of HO-2 cells is less than that of HO-1 cells in response to H_2O_2 toxicity. Performing subcellular fractionations revealed that HO-2 and CPR are found together in the microsomal fractions, whereas HO-1 is partially present in the microsome and also found in other fractions, such as the cytosol. These same findings were observed in non-transfected primary neurons where HO-1 proteins were chemically induced with 15-deoxy-$\Delta^{12,14}$-prostaglandin J_2 ($15dPGJ_2$). The differences in subcellular localization of HO-1 and HO-2 could explain some of the discrepancies in their cellular activity and enzymatic protective mechanisms.

3.587 Calpain and other cytosolic proteases can contribute to the degradation of retro-translocated prion protein in the cytosol

Wang, X., Wang, F., Sy, M-S- and Ma, J.
J. Biol. Chem., ***280(1)***, *317-325 (2005)*

PrP, a cell surface-localized *N*-linked glycoprotein, is required for the pathogenesis of prion diseases. Recent studies have revealed that prion protein (PrP) becomes neurotoxic and prone to aggregation when it is in the cytosol, suggesting that cytosolic PrP may play a role in the pathogenesis of prion disease. Retro-translocation of PrP from the endoplasmic reticulum to the cytosol for proteasome degradation offers a natural route for PrP to enter the cytosol, but whether PrP is subject to retrotranslocation is controversial. In this study, we investigated the metabolism of endogenous wild-type PrP in several cell lines and in primary mouse cortical neurons. Our results suggest that a portion of the endogenous wild-type PrP is retro-translocated to the cytosol and degraded by the proteasome. Moreover, we also found that calpain and other cytosolic proteases could degrade PrP in the cytosol when the proteasome activity is compromised. These results provide the foundation for the hypothesis that cytosolic PrP may be involved in the pathogenesis of prion disease.

3.588 Exogenous antigens are processed through the endoplasmic reticulum-associated degradatin (ERAD) in cross-presentation by dendritic cells

Imai, J., Hasegawa, H., Maruya, M., Koyasu, S. and Yahara, I.
Int. Immunol., ***17(1)***, *45-53 (2005)*

Antigen cross-presentation is critical in infectious and tumor immunity where cytotoxic T lymphocytes are induced by dendritic cells specifically equipped with cellular machineries to present exogenous antigens with major histocompatibility complex (MHC) class I molecules. To examine molecular mechanisms of antigen cross-presentation, we employed as a model system a murine dendritic cell line DC2.4 capable of presenting soluble antigens such as ovalbumin (OVA) with MHC class I. Here, we demonstrate that exogenously added OVA is accumulated in the endoplasmic reticulum (ER) and late endosomes followed by retrograde transport to the cytoplasm through the Sec61 transporter complexes, and that CHIP functions as an E3 ubiquitin–ligase for OVA degradation by proteasomes. This mechanism is essentially the same as that known as the ER-associated degradation (ERAD) in the quality control of secretary and membrane proteins.

3.589 Distinct localization of lipid rafts and externalized phosphotidylserine at the surface of apoptotic cells

Ishii, H. et al
Biochem. Biophys. Res. Comm., ***327***, *94-99 (2005)*

Externalization of phosphatidylserine (PS) takes place in apoptotic cells as well as in viable cells under certain circumstances. Recent studies showed that externalized PS is localized at the lipid raft in viable activated immune cells. We found that lipid rafts and PS existed in a mutually exclusive manner in apoptotic cells. The number of PS-exposing apoptotic cells decreased when lipid rafts were disrupted. BCθ, which binds selectively to cholesterol in a cholesterol-rich region, did not effectively recognize lipid rafts of apoptotic cells. Lipid rafts rich in GM1 were successfully prepared from apoptotic cells, but the lipid raft protein LAT was not enriched in the preparation. Furthermore, the amount of PS and phosphatidylethanolamine but not of cholesterol in lipid rafts appeared to change after induction of apoptosis. These results suggest that lipid rafts are structurally modified during apoptosis and, despite being localized differently from PS, are involved in the externalization of PS.

3.590 FAT/CD36-mediated long-chain fatty acid uptake in adipocytes requires plasma membrane rafts
Pohl, J., Ring, A., Korkmaz, U., Ehehalt, R and Stremmel, W.
*Mol. Biol. Cell, **16(1)**, 24-31 (2005)*

We previously reported that lipid rafts are involved in long-chain fatty acid (LCFA) uptake in 3T3-L1 adipocytes. The present data show that LCFA uptake does not depend on caveolae endocytosis because expression of a dominant negative mutant of dynamin had no effect on uptake of [^{3}H]oleic acid, whereas it effectively prevented endocytosis of cholera toxin. Isolation of detergent-resistant membranes (DRMs) from 3T3-L1 cell homogenates revealed that FAT/CD36 was expressed in both DRMs and detergent-soluble membranes (DSMs), whereas FATP1 and FATP4 were present only in DSMs but not DRMs. Disruption of lipid rafts by cyclodextrin and specific inhibition of FAT/CD36 by sulfo-*N*-succinimidyl oleate (SSO) significantly decreased uptake of [^{3}H]oleic acid, but simultaneous treatment had no additional or synergistic effects, suggesting that both treatments target the same mechanism. Indeed, subcellular fractionation demonstrated that plasma membrane fatty acid translocase (FAT/CD36) is exclusively located in lipid rafts, whereas intracellular FAT/CD36 cofractionated with DSMs. Binding assays confirmed that [^{3}H]SSO predominantly binds to FAT/CD36 within plasma membrane DRMs. In conclusion, our data strongly suggest that FAT/CD36 mediates raft-dependent LCFA uptake. Plasma membrane lipid rafts might control LCFA uptake by regulating surface availability of FAT/CD36.

3.591 Ypt3132 GTPases and their novel F-Box effector protein Rcy1 regulate protein recycling
Chen, S.H. et al
*Mol. Biol. Cell, **16(1)**, 178-192 (2005)*

Ypt/Rab GTPases control various aspects of vesicle formation and targeting via their diverse effectors. We report a new role for these GTPases in protein recycling through a novel effector. The F-box protein Rcy1, which mediates plasma membrane recycling, is identified here as a downstream effector of the Ypt31/32 GTPase pair because it binds active GTP-bound Ypt31/32 and colocalizes with these GTPases on late Golgi and endosomes. Furthermore, Ypt31/32 regulates the polarized localization and half-life of Rcy1. This suggests that Ypt/Rabs can regulate the protein level of their effectors, in addition to the established ways by which they control their effectors. We show that like Rcy1, Ypt31/32 regulate the coupled phosphorylation and recycling of the plasma membrane v-SNARE Snc1. Moreover, Ypt31/32 and Rcy1 regulate the recycling of the furin-homolog Kex2 to the Golgi. Therefore, Ypt31/32 and Rcy1 mediate endosome-to-Golgi transport, because this is the only step shared by Snc1 and Kex2. Finally, we show that Rcy1 physically interacts with Snc1. Based on this result and because F-box proteins serve as adaptors between specific substrates and ubiquitin ligases, we propose that Ypt31/32 GTPases regulate the function of Rcy1 in the phosphorylation and/or ubiquitination of proteins that recycle through the Golgi.

3.592 Trafficking and localization of platinum complexes in cisplatin-resistant cell lines monitored by fluorescence-labeled platinum
Liang, X-J. et al
*J. Cell. Physiol., **202**, 635-641 (2005)*

Cisplatin is a chemotherapeutic agent commonly used in the treatment of a wide variety of malignant tumors. Resistance to cisplatin represents a major obstacle to effective cancer therapy because clinically significant levels of resistance quickly emerge after treatment. Based on previous studies indicating abnormal plasma membrane protein trafficking in cisplatin-resistant (CP-r) cells, Fluorescence (Alexa Fluor)-labeled cisplatin was used to determine whether this defect altered the trafficking and localization

of cisplatin by comparing drug sensitive KB-3-1 and KB-CP-r cells. Alexa Fluor-cisplatin was readily internalized and localized throughout the KB-3-1 cells, but overall fluorescence decreased in KB-CP-r cells, as detected by flow cytometry (FACS) and confocal microscopy. Only punctate cytoplasmic staining was observed in KB-CP-r cells with less fluorescence observed in the nucleus. Colocalization experiments with a Golgi-selective stain indicate the involvement of Golgi-like vesicles in initial intracellular processing of Alexa Fluor conjugated cisplatin complexes. As detected using an antibody to Alexa Fluor-cisplatin, cisplatin complex-binding proteins (CCBPs) were reduced in membrane fractions of single-step cisplatin-resistant KB-CP.5 cells, and increased in the cytoplasm of KB-CP.5 cells compared to KB-3-1 cells. CCBPs localized to lower density fractions in KB-CP.5 cells than in KB-3-1 cells as determined by iodixanol gradient centrifugation. In summary, inappropriate trafficking of CCBPs might explain resistance to cisplatin in cultured cancer cells, presumably because membrane binding proteins for cisplatin are not properly located on the cell surface in these cells, but are instead trapped in low density vesicles within the cytoplasm.

3.593 Fragile X protein functions with LgI and the PAR complex in flies and mice
Zarnescu, D.C. et al
*Developmental Cell, **8**, 43-52 (2005)*

Fragile X syndrome, the most common form of inherited mental retardation, is caused by loss of function for the *Fragile X Mental Retardation 1* gene (*FMR1*). FMR1 protein (FMRP) has specific mRNA targets and is thought to be involved in their transport to subsynaptic sites as well as translation regulation. We report a saturating genetic screen of the *Drosophila* autosomal genome to identify functional partners of *dFmr1*. We recovered 19 mutations in the tumor suppressor *lethal (2) giant larvae* (*dlgl*) gene and 90 mutations at other loci. *dlgl* encodes a cytoskeletal protein involved in cellular polarity and cytoplasmic transport and is regulated by the PAR complex through phosphorylation. We provide direct evidence for a Fmrp/Lgl/mRNA complex, which functions in neural development in flies and is developmentally regulated in mice. Our data suggest that Lgl may regulate Fmrp/mRNA sorting, transport, and anchoring via the PAR complex.

3.594 Kaposi's sarcoma-associated herpesvirus modulates microtubele dynamics via RhoA-GTP-diaphanous 2 signaling and utilizes the dynein motors to deliver its DNA to the nucleus
Naranatt, P.P., Krishnan, H.H., Smith, M.S. and Chandran, B.
*J. Virol., **79(2)**, 1191-1206 (2005)*

Human herpesvirus 8 (HHV-8; also called Kaposi's sarcoma-associated herpesvirus), which is implicated in the pathogenesis of Kaposi's sarcoma (KS) and lymphoproliferative disorders, infects a variety of target cells both in vivo and in vitro. HHV-8 binds to several in vitro target cells via cell surface heparan sulfate and utilizes the α3ß1 integrin as one of its entry receptors. Interactions with cell surface molecules induce the activation of host cell signaling cascades and cytoskeletal changes (P. P. Naranatt, S. M. Akula, C. A. Zien, H. H. Krishnan, and B. Chandran, J. Virol. **77:**1524-1539, 2003). However, the mechanism by which the HHV-8-induced signaling pathway facilitates the complex events associated with the internalization and nuclear trafficking of internalized viral DNA is as yet undefined. Here we examined the role of HHV-8-induced cytoskeletal dynamics in the infectious process and their interlinkage with signaling pathways. The depolymerization of microtubules did not affect HHV-8 binding and internalization, but it inhibited the nuclear delivery of viral DNA and infection. In contrast, the depolymerization of actin microfilaments did not have any effect on virus binding, entry, nuclear delivery, or infection. Early during infection, HHV-8 induced the acetylation of microtubules and the activation of the RhoA and Rac1 GTPases. The inactivation of Rho GTPases by *Clostridium difficile* toxin B significantly reduced microtubular acetylation and the delivery of viral DNA to the nucleus. In contrast, the activation of Rho GTPases by *Escherichia coli* cytotoxic necrotizing factor significantly augmented the nuclear delivery of viral DNA. Among the Rho GTPase-induced downstream effector molecules known to stabilize the microtubules, the activation of RhoA-GTP-dependent diaphanous 2 was observed, with no significant activation in the Rac- and Cdc42-dependent PAK1/2 and stathmin molecules. The nuclear delivery of viral DNA increased in cells expressing a constitutively active RhoA mutant and decreased in cells expressing a dominant-negative mutant of RhoA. HHV-8 capsids colocalized with the microtubules, as observed by confocal microscopic examination, and the colocalization was abolished by the destabilization of microtubules with nocodazole and by the phosphatidylinositol 3-kinase inhibitor affecting the Rho GTPases. These results suggest that HHV-8 induces Rho GTPases, and in doing so, modulates microtubules and promotes the trafficking of viral capsids and the establishment of infection. This is the first demonstration of virus-induced host cell signaling pathways in the modulation of microtubule dynamics and in the trafficking of viral DNA to the

infected cell nucleus. These results further support our hypothesis that HHV-8 manipulates the host cell signaling pathway to create an appropriate intracellular environment that is conducive to the establishment of a successful infection.

3.595 Analyses of murine *Postsynaptic density-95* identify novel isoforms and potential translational control elements

Bence, M., Arbuckle, M.I., Dickson, K.S. and Grant, S.G.N.
*Mol. Brain res., **133(1)**, 143-152 (2005)*

Postsynaptic density-95 (PSD-95) is an evolutionarily conserved synaptic adaptor protein that is known to bind many proteins including the NMDA receptor. This observation has implicated it in many NMDA receptor-dependent processes including spatial learning and synaptic plasticity. We have cloned and characterised the murine *PSD-95* gene. In addition, we have identified two previously uncharacterised splice variants of the major murine PSD-95 transcript (*PSD-95α*): *PSD-95α-2b* results from an extension of exon 2 and *PSD-95α-Δ18* from the temporal exclusion of exon 18. The presence of PSD-95α-2b sequences in other PSD-95 family members implicates this peptide stretch as functionally significant. Another potential transcript (*PSD-95γ*) was also identified based on examination of EST databases. Immunoprecipitation assays demonstrate that proteins corresponding in size to PSD-95α-Δ18 and PSD-95γ interact with the NMDA receptor, suggesting an important biological role for these isoforms. Finally, we have performed bioinformatics analyses of the PSD-95 mRNA untranslated regions, identifying multiple translational control elements that suggest protein production could be regulated post-transcriptionally. The variety of mRNA isoforms and regulatory elements identified provides for a high degree of diversity in the structure and function of PSD-95 proteins.

3.596 Isoform-specific regulation of adenylyl cylase function by disruption of membrane trafficking

Ding, Q., Gros, R., Chorazyczewski, J., Ferguson, S.S.g. and Feldman, R.D.
*Mol. Pharmacol., **6782)**, 564-571 (2005)*

Oligomerization plays an important role in endoplasmic reticulum processing and membrane insertion (and ultimately in regulation of function) of a number of transmembrane spanning proteins. Furthermore, it is known that adenylyl cyclases (ACs), critical regulators of cellular functions, associate into higher order (dimeric) forms. However, the importance of these higher order aggregates in regulating adenylyl cyclase activity or trafficking to the cell membrane is unclear. Therefore, we examined the potential role of oligomerization in the membrane trafficking of adenylyl cyclase. For this purpose, the ability of full-length adenylyl cyclase and various truncation mutants to self-assemble and to be targeted to the cell membrane was assessed. A truncation mutant comprised of the initial six transmembrane spanning domains and half of the C1 catalytic domain coimmunoprecipitated with full-length AC VI. Using both biotinylation assays and assessment of enzyme distribution using sucrose density gradients, we demonstrate that expression of this mutant in human embryonic kidney 293 cells impaired the ability of AC VI to traffic to the plasma membrane. Furthermore, mutant expression resulted in a significant reduction in adenylyl cyclase activity. The decrease in AC VI membrane expression was not caused by alterations in enzyme transcription. The effect of the mutant was specific for the AC V and VI isoforms and expression of the transmembrane M1 domain but not the C1a domain was required for the mutant to affect adenylyl cyclase activity. In aggregate, these data suggest that alterations in the ability of adenylyl cyclases to form higher order forms regulate both enzyme trafficking and enzyme activity.

3.597 Fractionation of the epithelial apical junctional complex: reassessment of protein distributions in different substructures

Vogelmann, R. And Nelson, W.J.
*Mol. Biol. Cell, **16**, 701-716 (2005)*

The epithelial apical junctional complex (AJC) is an important regulator of cell structure and function. The AJC is compartmentalized into substructures comprising the tight and adherens junctions, and other membrane complexes containing the membrane proteins nectin, junctional adhesion molecule, and crumbs. In addition, many peripheral membrane proteins localize to the AJC. Studies of isolated proteins indicate a complex map of potential binding partners in which there is extensive overlap in the interactions between proteins in different AJC substructures. As an alternative to a direct search for specific protein-protein

interactions, we sought to separate membrane substructures of the AJC in **iodixanol** density gradients and define their protein constituents. Results show that the AJC can be fractured into membrane substructures that contain specific membrane and peripheral membrane proteins. The composition of each substructure reveals a more limited overlap in common proteins than predicted from the inventory of potential interactions; some of the overlapping proteins may be involved in stepwise recruitment and assembly of AJC substructures.

3.598 Roles of the ITAM and PY motifs of Epstein-Barr virus latent membrane protein 2A in the inhibition of epithelial cell differentiation and activation of β-catenin signaling
Morrison, J.A. and Raab-Traub, N.
J. Virol., ***79(4)***, *2375-2382 (2005)*

Epstein-Barr virus (EBV) latent membrane protein 2A (LMP2A) is important for maintenance of latency in infected B lymphocytes. Through its immunoreceptor tyrosine-based activation motif (ITAM) and PY motifs, LMP2A is able to block B-cell receptor (BCR) signaling, bind BCR-associated kinases, and manipulate the turnover of itself and these kinases via a PY-mediated interaction with the Nedd4 family of ubiquitin ligases. In epithelial cells, LMP2A has been shown to activate the phosphatidylinositol 3'-OH kinase/Akt and ß-catenin signaling pathways. In the present study, the biological consequences of LMP2A expression in the normal human foreskin keratinocyte (HFK) cell line were investigated and the importance of the ITAM and PY motifs for LMP2A signaling effects in HFK cells was ascertained. The ITAM was essential for the activation of Akt by LMP2A in HFK cells, while both the ITAM and PY motifs contributed to LMP2A-mediated accumulation and nuclear translocation of the oncoprotein ß-catenin. LMP2A inhibited induction of differentiation in an assay conducted with semisolid methylcellulose medium, and the PY motifs were critical for this inhibition. LMP2A is expressed in the EBV-associated epithelial malignancies nasopharyngeal carcinoma and gastric carcinoma, and these data indicate that LMP2A affects cellular processes that likely contribute to carcinogenesis.

3.599 Alteration of the extracellular matrix interferes with raft association of neurofascin in oligodendrocytes. Potential significance for multiple sclerosis
Maier, O. Et al
Mol. Cell. Neurosci., ***28(2)***, *390-401 (2005)*

Remyelination, as potential treatment for demyelinating diseases like multiple sclerosis (MS), requires the formation of new axoglial interactions by differentiating oligodendrocyte progenitor cells. Since the oligodendrocyte-specific isoform of neurofascin, NF155 (neurofascin isoform of 155 kDa), may be important for establishing axoglial interactions, we analyzed whether its expression is changed in chronic relapsing experimental allergic encephalomyelinitis (EAE). Although overall expression of NF155 was not changed, immunoreactivity of NF155 was dramatically increased in EAE lesion sites indicating an enhanced accessibility of NF155 epitopes. As this may be due to infiltrating plasma components, for example, fibronectin, we analyzed whether fibronectin affects the intracellular distribution and membrane association of NF155 in primary oligodendrocytes. In oligodendrocytes cultivated on polylysine, NF155 was recruited to membrane microdomains (rafts) during development and became enriched in secondary and tertiary processes. Fibronectin perturbed localization and raft association of NF155 and inhibited the morphological differentiation of oligodendrocytes. Consistent with the in vitro data, raft association of NF155 was reduced in spinal cord of EAE rats. The results suggest that the association of NF155 to microdomains in the oligodendrocyte membrane is required for its participation in intermolecular interactions, which are important for myelination and/or myelin integrity.

3.600 Characterizing the sphingolipid signaling pathway that remediates defects associated with loss of the yeast amphiphysin-like orthologs, Rvs161p and Rvs167p
Germann, M., Swain, E., Bergman, L. and Nickels, Jr. J.T.
J. Biol. Chem., ***280(6)***, *4270-4278 (2005)*

Loss of function of either the *RVS161* or *RVS167 Saccharomyces cerevisiae* amphiphysin-like gene confers similar growth phenotypes that can be suppressed by mutations in sphingolipid biosynthesis. We performed a yeast two-hybrid screen using Rvs161p as bait to uncover proteins involved in this sphingolipid-dependent suppressor pathway. In the process, we have demonstrated a direct physical interaction between Rvs167p and the two-hybrid interacting proteins, Acf2p, Gdh3p, and Ybr108wp, while also elucidating the Rvs167p amino acid domains to which these proteins bind. By using subcellular fractionation, we demonstrate that Rvs167p, Ybr108wp, Gdh3p, and Acf2p all localize to Rvs161p-containing lipid rafts,

thus placing them within a single compartment that should facilitate their interactions. Moreover, our results suggest that Acf2p and Gdh3p functions are needed for suppressor pathway activity. To determine pathway mechanisms further, we examined the localization of Rvs167p in suppressor mutants. These studies reveal roles for Rvs161p and the very long chain fatty acid elongase, Sur4p, in the localization and/or stability of Rvs167p. Previous yeast studies showed that *rvs* defects could be suppressed by changes in sphingolipid metabolism brought about by deleting *SUR4* (Desfarges, L., Durrens, P., Juguelin, H., Cassagne, C., Bonneu, M., and Aigle, M. (1993) *Yeast* 9, 267–277). Using *rvs167 sur4* and *rvs161 sur4* double null cells as models to study suppressor pathway activity, we demonstrate that loss of *SUR4* does not remediate the steady-state actin cytoskeletal defects of *rvs167* or *rvs161* cells. Moreover, suppressor activity does not require the function of the actin-binding protein, Abp1p, or Sla1p, a protein that is thought to regulate assembly of the cortical actin cytoskeleton. Based on our results, we suggest that sphingolipid-dependent suppression of *rvs* defects may not work entirely through regulating changes in actin organization.

3.601 Internalization of renal type Iic Na-P_i cotransporter in response to a high-phosphate diet
Segawa, H. et al
*Am. J. Renal Physiol., **288**, F587-F596 (2005)*

Dietary phosphate levels regulate the renal brush-border type IIa Na-P_i cotransporter. Another Na-P_i cotransporter, type IIc, colocalizes with type IIa Na-P_i cotransporter in the apical membrane of renal proximal tubular cells. The goal of the present study was to determine whether dietary phosphate levels also rapidly regulate the type IIc Na-P_i cotransporter. Type IIa and type IIc transporter protein levels were increased in rats chronically fed a low-P_i diet compared with those fed a normal-P_i diet. Two hours after beginning a high-P_i diet, type IIa transporter levels were decreased, whereas type IIc protein levels remained unchanged. Western blot analysis of brush-border membrane prepared 4 h after beginning a high-P_i diet showed a significant reduction in type IIc transporter protein levels, and immunohistochemistry showed translocation of the type IIc-immunoreactive signal from the entire brush border to subapical membrane. Membrane fractionation studies revealed a decrease in apical membrane type IIc protein without changes in total cortical type IIc protein, which is compatible with redistribution of type IIc protein from the apical membrane to the dense membrane fraction. The microtubule-disrupting reagent colchicine prevented this reduction in apical type IIc transporter at the apical membrane but had no effect on type IIa transporter levels. These data suggest that the type IIc Na-P_i cotransporter level is rapidly regulated by rapid adaptation to dietary P_i in a microtubule-dependent manner. Furthermore, the mechanisms of the internalization of the type IIc transporter are distinct from those of the type IIa transporter.

3.602 Phosphorylation-induced autoinhibition regulates the cytoskeletal protein lethal (2) giant larvae
Betschinger, J., Eisenhaber, F. and Knoblich, J.A.
*Current Biol., **15(3)**, 276-282 (2005)*

During asymmetric cell division, cell fate determinants localize asymmetrically and segregate into one of the two daughter cells. In *Drosophila* neuroblasts, the asymmetric localization of cell fate determinants to the basal cell cortex requires aPKC. aPKC localizes to the apical cell cortex and phosphorylates the cytoskeletal protein Lethal (2) giant larvae (Lgl). Upon phosphorylation, Lgl dissociates from the cytoskeleton and becomes inactive. Here, we show that phosphorylation regulates Lgl by allowing an autoinhibitory interaction of the N terminus with the C terminus of the protein. We demonstrate that interaction with the cytoskeleton is mediated by a C-terminal domain while the N terminus is not required. Instead, the N terminus can bind to the C terminus and can compete for binding to the cytoskeleton. Interaction between the N- and C-terminal domains requires phosphorylation of Lgl by aPKC. Our results suggest that unphosphorylated, active Lgl exists in an open conformation that interacts with the cytoskeleton while phosphorylation changes the protein to an autoinhibited state.

3.603 Annexin 2 promotes the formation of lipid microdomains required for calcium-regulated exocytosis of dense-core vesicles
Chasserot-Golaz, S. et al
*Mol. Biol. Cell, **16**, 1108-1119 (2005)*

Annexin 2 is a calcium-dependent phospholipid-binding protein that has been implicated in a number of membranerelated events, including regulated exocytosis. In chromaffin cells, we previously reported that catecholamine secretion requires the translocation and formation of the annexin 2 tetramer near the exocytotic sites. Here, to obtain direct evidence for a role of annexin 2 in exocytosis, we modified its

expression level in chromaffin cells by using the Semliki Forest virus expression system. Using a real-time assay for individual cells, we found that the reduction of cytosolic annexin 2, and the consequent decrease of annexin 2 tetramer at the cell periphery, strongly inhibited exocytosis, most likely at an early stage before membrane fusion. Secretion also was severely impaired in cells expressing a chimera that sequestered annexin 2 into cytosolic aggregates. Moreover, we demonstrate that secretagogue-evoked stimulation triggers the formation of lipid rafts in the plasma membrane, essential for exocytosis, and which can be attributed to the annexin 2 tetramer. We propose that annexin 2 acts as a calcium-dependent promoter of lipid microdomains required for structural and spatial organization of the exocytotic machinery.

3.604 The deubiquitinating enzyme Ubp1 affects sorting of the ATP-binding cassette-transporter Ste6 in the endocytic pathway
Schmitz, C., Kinner, A. and Kölling, R.
*Mol. Biol. Cell, **16**, 1319-1329 (2005)*

Deubiquitinating enzymes (Dubs) are potential regulators of ubiquitination-dependent processes. Here, we focus on a member of the yeast ubiquitin-specific processing protease (Ubp) family, the Ubp1 protein. We could show that Ubp1 exists in two forms: a longer membrane-anchored form (mUbp1) and a shorter soluble form (sUbp1) that seem to be independently expressed from the same gene. The membrane-associated mUbp1 variant could be localized to the endoplasmic reticulum (ER) membrane by sucrose density gradient centrifugation and by immunofluorescence microscopy. Overexpression of the soluble Ubp1 variant stabilizes the ATP-binding cassette-transporter Ste6, which is transported to the lysosome-like vacuole for degradation, and whose transport is regulated by ubiquitination. Ste6 stabilization was not the result of a general increase in deubiquitination activity, because overexpression of Ubp1 had no effect on the degradation of the ER-associated degradation substrate carboxypeptidase Y^* and most importantly on Ste6 ubiquitination itself. Also, overexpression of another yeast Dub, Ubp3, had no effect on Ste6 turnover. This suggests that the Ubp1 target is a component of the protein transport machinery. On Ubp1 overexpression, Ste6 accumulates at the cell surface, which is consistent with a role of Ubp1 at the internalization step of endocytosis or with enhanced recycling to the cell surface from an internal compartment.

3.605 A domain at the C-terminus of PS1 is required for presenilinase and γ-secretase activities
Brunkan, A.L., Martinez, M., Wang, J., Walker, E.S. and Goate, A.M.
*J. Neurochem., **92(5)**, 1158-1169 (2005)*

The structural requirements for presenilin (PS) to produce active presenilinase and γ-secretase enzymes are poorly understood. Here we investigate the role the cytoplasmic C-terminal region of PS1 plays in PS1 activity. Deletion or addition of residues at the PS C-terminus has been reported to inhibit presenilinase endoproteolysis of PS and alter γ-secretase activity. In this study, we use a sensitive assay in PS1/2KO MEFs to define a domain at the extreme C-terminus of PS1 that is essential for both presenilinase and γ-secretase activities. Progressive deletion of the C-terminus demonstrated that removal of nine residues produces a PS1 molecule (458ST) that lacks both presenilinase processing and γ-secretase cleavage of Notch and APP substrates. In contrast, removal of four or five residues had no effect (462ST, 463ST), while intermediate truncations partially inhibited PS1 activity. The 458ST mutant was unable to replace endogenous wtPS1 in HEK293 cells. Although 458ST was able to form a γ-secretase complex, this complex was not matured, illustrated by mutant PS1 instability, lack of endoproteolysis, and little production of mature Nicastrin. These data indicate that the C-terminal end of PS1 is essential for Nicastrin trafficking and modification as well as the replacement of endogenous PS1 by PS1 transgenes.

3.606 Novel role of ARF6 in vascular endothelial growth factor-induced signaling and angiogenesis
Ikeda, S. et al
*Cir. Res., **96**, 467-475 (2005)*

Vascular endothelial growth factor (VEGF) stimulates endothelial cell (EC) migration and proliferation primarily through the VEGF receptor-2 (VEGFR2). We have shown that VEGF stimulates a Rac1-dependent NAD(P)H oxidase to produce reactive oxygen species (ROS) that are involved in VEGFR2 autophosphorylation and angiogenic-related responses in ECs. The small GTPase ARF6 is involved in membrane trafficking and cell motility; however, its roles in VEGF signaling and physiological responses in ECs are unknown. In this study, we show that overexpression of dominant-negative ARF6 [ARF6(T27N)] almost completely inhibits VEGF-induced Rac1 activation, ROS production, and VEGFR2 autophosphorylation in ECs. Fractionation of caveolae/lipid raft membranes demonstrates that ARF6, Rac1,

and VEGFR2 are localized in caveolin-enriched fractions basally. VEGF stimulation results in the release of VEGFR2 from caveolae/lipid rafts and caveolin-1 without affecting localization of ARF6, Rac1, or caveolin-1 in these fractions. The egress of VEGFR2 from caveolae/lipid rafts is contemporaneous with the tyrosine phosphorylation of caveolin-1 (Tyr14) and VEGFR2 and with their association with each other. ARF6(T27N) significantly inhibits both VEGF-induced responses. Immunofluorescence studies show that activated VEGFR2 and phosphocaveolin colocalize at focal complexes/adhesions after VEGF stimulation. Both overexpression of ARF6(T27N) and mutant caveolin-1(Y14F), which cannot be phosphorylated, block VEGF-stimulated EC migration and proliferation. Moreover, ARF6 expression is markedly upregulated in association with an increase in capillary density in a mouse hindlimb ischemia model of angiogenesis. Thus, ARF6 is involved in the temporal-spatial organization of caveolae/lipid rafts– and ROS-dependent VEGF signaling in ECs as well as in angiogenesis in vivo.

3.607 Stable plasma membrane levels of hCTR1 mediate cellular copper uptake
Eisses, J.F., Chi, Y. and Kaplan, J.H.
J. Biol. Chem., ***280(10)***, *9635-9639 (2005)*

The human copper transporter 1 (hCtr1), when heterologously overexpressed in insect cells, mediates saturable Cu uptake. In mammalian expression systems, a rapid Cu-dependent internalization of hCtr1 has been reported in cells that overexpress epitope-tagged hCtr1 when exposed to Cu in the external medium. This finding led to the suggestion that such internalization may be a step in the hCtr1 transmembrane Cu transport mechanism. We have demonstrated that preincubation in Cu-containing media of *sf9* cells stably expressing hCtr1 has no effect on the initial rate of Cu transport. Furthermore, Western blot analyses of fractionated *sf9* cell membranes show no evidence of a regulatory Cu-dependent internalization from the plasma membrane. In similar studies on human embryonic kidney (HEK) 293 cells, we showed that incubation with Cu does not alter the initial rate of Cu uptake mediated by endogenous levels of hCtr1 compared with untreated cells. Confirmation that hCtr1 mediates this transport is provided by specific small interfering RNA-dependent decreases in hCtr1 protein levels and in Cu transport rates. Western blot analysis and confocal microscopy of human embryonic kidney 293 cells showed that the majority of hCtr1 protein is localized at the plasma membrane and no significant internalization is detected upon Cu treatment. We concluded that internalization of hCtr1 is not a required step in the transport pathway; we suggest that oligomeric hCtr1 acts as a conventional transporter providing a permeation pathway for Cu through the membrane and that internalization of endogenous hCtr1 in response to elevated extracellular Cu levels does not play a significant regulatory role in Cu homeostasis.

3.608 Membrane localization of the U2 domain of protein 4.1B is necessary and sufficient for meningioma growth suppression
Robb, V.A., Gerber, M.A., Hart-Mahon, E.K. and Gutmann, D.H.
Oncogene, ***24****, 1946-1957 (2005)*

Meningiomas are common central nervous system tumors; however, the molecular mechanisms underlying their pathogenesis are largely undefined. Previous work has implicated Protein 4.1B as an important tumor suppressor involved in the development of these neoplasms. In this report, we demonstrate that the U2 domain is necessary and sufficient for the ability of Protein 4.1B to function as a meningioma growth suppressor. Using a series of truncation and deletion constructs of DAL-1 (a fragment of Protein 4.1B that retains all the growth suppressive properties), we narrowed the domain required for 4.1B growth suppression to a fragment containing a portion of the FERM domain and the U2 domain using clonogenic assays on meningioma cells. Deletion of the U2 domain in the context of the full-length DAL-1 molecule eliminated growth suppressor function, as measured by thymidine incorporation and caspase-3 activation. Moreover, targeting the U2 domain to the plasma membrane using a membrane localization signal (MLS) reduced cell proliferation, similar to wild-type DAL-1. Collectively, the data suggest that the U2 domain, when properly targeted to the plasma membrane, contains all the residues necessary for mediating Protein 4.1B growth suppression.

3.609 Nuclear location-dependent role of peripheral benzodiapine receptor (PBR) in hepatic tumoral cell lines proliferation
Corsi, L., Geminiani, E., Avallone, R. and Baraldi, M.
Life Sciences, ***76(22)****, 2523-2533 (2005)*

PBR is involved in numerous biological functions, including steroid biosynthesis, mitochondrial oxidative phosphorylation and cell proliferation. The presence of PBR at the perinuclear/nuclear subcellular level

has been demonstrated in aggressive breast cancer cell lines and human glioma cells where it seems to be involved in cell proliferation. In our study we investigated the presence of perinuclear/nuclear PBR in different hepatic tumor cell lines with regard to binding to [^{3}H] PK 11195 and protein analysis. The results obtained by saturation binding experiments and scatchard analysis of perinuclear/nuclear PBR density in parallel with the results on the growth curves of the cell lines tested, indicate that the perinuclear/nuclear PBR density correlates inversely with cell doubling time. Moreover, the cell line with high perinuclear/nuclear PBR proliferated in response to PBR ligand, whereas that with low perinuclear/nuclear PBR did not. Our results reinforce the idea that the subcellular localisation of PBR defines its function and that this receptor could be a possible target for new strategies against cancer.

3.610 Two modes of exocytosis at hippocampal synapses revealed by rate of FM1-43 efflux from individual vesicles
Richards, D.A., Bai, J. and Chapman, E.R.
J. Cell Biol., ***168(6)***, *929-939 (2005)*

We have examined the kinetics by which FM1-43 escapes from individual synaptic vesicles during exocytosis at hippocampal boutons. Two populations of exocytic events were observed; small amplitude events that lose dye slowly, which made up more than half of all events, and faster, larger amplitude events with a fluorescence intensity equivalent to single stained synaptic vesicles. These populations of destaining events are distinct in both brightness and kinetics, suggesting that they result from two distinct modes of exocytosis. Small amplitude events show tightly clustered rate constants of dye release, whereas larger events have a more scattered distribution. Kinetic analysis of the association and dissociation of FM1-43 with membranes, in combination with a simple pore permeation model, indicates that the small, slowly destaining events may be mediated by a narrow ~1-nm fusion pore.

3.611 Neutral sphingomyelinase 2 (*smpd3*) in the control of postnatal growth and development
Stoffel, W., Jenke, B., Blöck, B., Zumbansen, M. And Koebke, J.
PNAS, ***102(12)***, *4554-4559 (2005)*

Neutral sphingomyelinases sphingomyelin phosphodiesterase (SMPD)2 and -3 hydrolyze sphingomyelin to phosphocholine and ceramide. *smpd2* is expressed ubiquitously, and *smpd3* is expressed predominantly in neurons of the CNS. Their activation and the functions of the released ceramides have been associated with signaling pathways in cell growth, differentiation, and apoptosis. However, these cellular responses remain poorly understood. Here we describe the generation and characterization of the *smpd3*$^{-/-}$ and *smpd2*$^{-/-}$ *smpd3*$^{-/-}$ double mutant mouse, which proved to be devoid of neutral sphingomyelinase activity. SMPD3 plays a pivotal role in the control of late embryonic and postnatal development: the *smpd3*-null mouse develops a novel form of dwarfism and delayed puberty as part of a hypothalamus-induced combined pituitary hormone deficiency. Our studies suggest that SMPD3 is segregated into detergent-resistant subdomains of Golgi membranes of hypothalamic neurosecretory neurons, where its transient activation modifies the lipid bilayer, an essential step in the Golgi secretory pathway. The *smpd3*$^{-/-}$ mouse might mimic a form of human combined pituitary hormone deficiency.

3.612 Caveolae targeting and regulation of large conductance Ca^{2+} -activated K^+ channels in vascular endothelial cells
Wang, X-L. et al
J. Biol. Chem., ***280(12)***, *11656-11664 (2005)*

The vascular endothelium is richly endowed with caveolae, which are specialized membrane microdomains that facilitate the integration of specific cellular signal transduction processes. We found that the large conductance Ca^{2+}-activated K^+ (BK) channels are associated with caveolin-1 in bovine aortic endothelial cells (BAECs). **OptiPrep** gradient cell fractionation demonstrated that BK channels were concentrated in the caveolae-rich fraction in BAECs. Immunofluorescence imaging showed co-localization of caveolin-1 and BK channels in the BAEC membrane. Immunoprecipitation and glutathione *S*-transferase pull-down assay results indicated that caveolin-1 and BK channels are physically associated. However, whole cell patch clamp recordings could not detect BK (iberiotoxin-sensitive) currents in cultured BAECs under baseline conditions, even though the presence of BK mRNA and protein expression was confirmed by reverse transcription-PCR and Western blots. Cholesterol depletion redistributed the BK channels to non-caveolar fractions of BAECs, resulting in BK channel activation (7.3 ± 1.6 pA/picofarad (pF), n = 5). BK currents were also activated by isoproterenol (ISO, 1 μM, 6.9 ± 2.4 pA/pF, n = 6). Inclusion of a caveolin-1 scaffolding domain peptide (10 μM) in the pipette solution completely abrogated

the effects of ISO on BK channel activation, whereas inclusion of the scrambled control peptide (10 μM) did not inhibit the ISO effects. We have also found that caveolin-1 knockdown by small interference RNA activated BK currents (5.3 ± 1.4 pA/pF, $n = 6$). We conclude that: 1) BK channels are targeted to caveolae microdomains in vascular endothelial cells; 2) caveolin-1 interacts with BK channels and exerts a negative regulatory effect on channel functions; and 3) BK channels are inactive under control conditions but can be activated by cholesterol depletion, knockdown of caveolin-1 expression, or ISO stimulation. These novel findings may have important implications for the role of BK channels in the regulation of endothelial function.

3.613 Aph-1 contributes to the stabilization and trafficking of the γ-secretase complex through mechanisms involving intermolecular and intramolecular interactions
Niimura, M. Et al
J. Biol. Chem., ***280(13)***, *12967-12975 (2005)*

γ-Secretase cleaves type I transmembrane proteins, including β-amyloid precursor protein and Notch, and requires the formation of a protein complex comprised of presenilin, nicastrin, Aph-1, and Pen-2 for its activity. Aph-1 is implicated in the stabilization of this complex, although its precise mechanistic role remains unknown. Substitution of the first glycine within the transmembrane G*XXX*G motif of Aph-1 causes a loss-of-function phenotype in *Caenorhabditis elegans*. Here, using an untranslated region-targeted RNA interference/rescue strategy in *Drosophila* Schneider 2 cells, we show that Aph-1 contributes to the assembly of the γ-secretase complex by multiple mechanisms involving intermolecular and intramolecular interactions depending on or independent of the conserved glycines. Aph-1 binds to nicastrin forming an early subcomplex independent of the conserved glycines within the endoplasmic reticulum. Certain mutations in the conserved G*XXX*G motif affect the interaction of the Aph-1·nicastrin subcomplex with presenilin that mediates trafficking of the presenilin·Aph-1·nicastrin tripartite complex to the Golgi. The same mutations decrease the stability of Aph-1 polypeptides themselves, possibly by affecting intramolecular associations through the transmembrane domains. Our data suggest that the proper assembly of the Aph-1·nicastrin subcomplex with presenilin is the prerequisite for the trafficking as well as the enzymatic activity of the γ-secretase complex and that Aph-1 functions as a stabilizing scaffold in the assembly of this complex.

3.614 Molecular mechanisms of cholesterol absorption and transport in the intestine
Hui, D.Y. and Howles, P.N.
Seminars in Cell & Developmental Biol., ***16(2)***, *183-192 (2005)*

Many enzymes and transport proteins participate in cholesterol absorption. This review summarizes recent results on several proteins that are important for each step of the cholesterol absorption pathway, including the important roles of: (i) pancreatic triglyceride lipase (PTL), carboxyl ester lipase (CEL), and ileal bile acid transporter in determining the rate of cholesterol absorption; (ii) ATP binding cassette (ABC) transporters and the Niemann-Pick C-1 like-1 (NPC1L1) protein as intestinal membrane gatekeepers for cholesterol efflux and influx; and (iii) intracellular membrane vesicles and transport proteins in lipid trafficking through intracellular compartments prior to lipoprotein assembly and secretion to plasma circulation.

3.615 Adeno-associated virus-mediated gene transfer of the heart/muscle adenine nucleotide translocator (ANT) in mouse
Flierl, A., Chen, Y., Coskun, P.E., Samulski, R.J. and Wallace, D.C.
Gen. Ther., ***12***, *570-578 (2005)*

Mitochondrial myopathy, associated with muscle weakness and progressive external ophthalmoplegia, is caused by mutations in mitochondria oxidative phosphorylation genes including the heart–muscle isoform of the mitochondrial adenine nucleotide translocator (ANT1). To develop therapies for mitochondrial disease, we have prepared a recombinant adeno-associated viral vector (rAAV) carrying the mouse Ant1 cDNA. This vector has been used to transduce muscle cells and muscle from Ant1 mutant mice, which manifest mitochondrial myopathy. AAV-ANT1 transduction resulted in long-term, stable expression of the Ant1 transgene in muscle precursor cells as well as differentiated muscle fibers. The transgene ANT1 protein was targeted to the mitochondrion, was inserted into the mitochondrial inner membrane, formed a functional ADP/ATP carrier, increased the mitochondrial export of ATP and reversed the histopathological changes associated with the mitochondrial myopathy. Thus, AAV transduction has the potential of

providing symptomatic relief for the ophthalmoplegia and ptosis resulting from paralysis of the extraocular eye muscles cause by mutations in the Ant1 gene.

3.616 Nulear localization anti-DNA antibodies enter cells via caveoli and modulate expression of caveolin and p53

Yanase, K. and Madaio, M.P.
J. Autoimmun., ***24****, 145-151 (2005)*

After administration to normal mice, a subset of monoclonal (m) anti-DNA antibodies (Ab) derived from MRL-*lpr/lpr* mice was identified that enter cells, in vivo. In the kidneys, this was associated with glomerular hypercellularity and proteinuria. In cultured cells, the same mAb bound to myosin 1 on the cell surface, prior to internalization, nuclear localization and inhibition of apoptosis. The present study focuses on the mechanisms underlying the observed functional effects. Subcellular localization studies revealed that following internalization, a prototypic, nuclear localizing, m antibody (Ab; termed H7) co-localized with myosin 1, shortly after internalization, within caveolae, near the cell membrane. Cell fractionation studies confirmed the presence of both H7 and myosin within the caveolar fraction. Since variations in caveolin protein expression have been associated with apoptotic events in cancer cells, through p53 dependent and independent pathways, modulation of caveolin by intracellular H7 was evaluated. Cellular entry of the anti-DNA Ab resulted in an increase in caveolin protein expression. Furthermore, after exposure of cells to dexamethasone to induce apoptosis, the usual increase in p53 was inhibited in the presence of intracellular H7. Taken together, the results suggest that upregulation of caveolin and inhibition of p53 induction are involved in H7-induced, inhibition of apoptosis. Furthermore, they suggest that this inhibition contributes to the glomerular hypercellularity observed in normal mice with intranuclear H7. The results also raise the possibility that inhibition of apoptotic pathways during inflammation or/and autoimmunity could influence subsequent disease events. The novel mechanism of cellular perturbation is indirect and dependent on apoptotic stimuli, and it may account for the presence of intranuclear antibodies in inflammatory and normal tissues of individuals with lupus.

3.617 A simplified method for the preparation of detergent-free lipid rafts

Macdonald, J.L. and Pike, L.J.
J. Lipid. Res., ***46****, 1061-1067 (2005)*

Lipid rafts are small plasma membrane domains that contain high levels of cholesterol and sphingolipids. Traditional methods for the biochemical isolation of lipid rafts involve the extraction of cells with nonionic detergents followed by the separation of a low-density, detergent-resistant membrane fraction on density gradients. Because of concerns regarding the possible introduction of artifacts through the use of detergents, it is important to develop procedures for the isolation of lipid rafts that do not involve detergent extraction. We report here a simplified method for the purification of detergent-free lipid rafts that requires only one short density gradient centrifugation, but yields a membrane fraction that is highly enriched in cholesterol and protein markers of lipid rafts, with no contamination from nonraft plasma membrane or intracellular membranes.

3.618 Studies on rabbit natural and recombinant tissue factors: intracellular retention and regulation of surface expression in cultured cells

Fortin, J-P., Rivard, G.E., Adam, A. and Marceau, F.
Am. J. Physiol., ***288****, H2192-H2202 (2005)*

Tissue factor (TF) is the most important trigger of blood coagulation in vascular pathology. Rabbit TF, with or without (ΔC) its COOH-terminal intracellular tail, has been conjugated to green fluorescent protein (GFP) to study subcellular localization and other functions of TF. TF-GFP and TFΔC-GFP are associated with Na_2CO_3-resistant buoyant fractions in HEK-293 cells (lipid rafts); there is no morphological difference in the surface distribution of these or other GFP-labeled membrane proteins present in or excluded from rafts (confocal microscopy, HEK-293 cells). Endogenous TF expressed by rabbit aortic smooth muscle cells (SMCs) is also raft associated. Membranes from HEK-293 cells expressing recombinant TF-GFP or wild-type TF were equipotent to clot human plasma; however, TFΔC-GFP was ~ 20-fold more active (per membrane weight). Immunoblot confirmed that the deletion mutant is more abundantly expressed, and confocal microscopy showed that it has preferential membrane localization, whereas TF-GFP is mainly intracellular (nuclear lining and multiple granules). With a similar half-life (<4 h), the two constructions differ by their intracellular retention, lower for TFΔC-GFP. In serum-starved SMCs, the expression of endogenous TF was upregulated by interleukin-1β and/or FBS treatment

(immunoblot, immunofluorescence, clotting assay). However, TF secretion or surface expression was not regulated by stimuli of physiological intensity (such as stimulation of the coexpressed kinin B_1 receptors), although a calcium ionophore was highly active in this respect. TF is a raft-associated molecule whose surface expression (secretion) is apparently retarded or impaired by structural determinant(s) located in its COOH-terminal tail.

3.619 Proteomic profiling of hepatic endoplasmic reticulum-associated proteins in an animal model of insulin resistance and metabolic dyslipidemia
Morand, J-P. F., Macri, J. and Adeli, K.
J. Biol. Chem., ***280(18)***, *17626-17633 (2005)*

Hepatic insulin resistance and lipoprotein overproduction are common features of the metabolic syndrome and insulin-resistant states. A fructose-fed, insulin-resistant hamster model was recently developed to investigate mechanisms linking the development of hepatic insulin resistance and overproduction of atherogenic lipoproteins. Here we report a systematic analysis of protein expression profiles in the endoplasmic reticulum (ER) fractions isolated from livers of fructose-fed hamsters with the intention of identifying new candidate proteins involved in hepatic complications of insulin resistance and lipoprotein dysregulation. We have profiled hepatic ER-associated proteins from chow-fed (control) and fructose-fed (insulin-resistant) hamsters using two-dimensional gel electrophoresis and mass spectrometry. A total of 26 large scale two-dimensional gels of hepatic ER were used to identify 34 differentially expressed hepatic ER protein spots observed to be at least 2-fold differentially expressed with fructose feeding and the onset of insulin resistance. Differentially expressed proteins were identified by matrix-assisted laser desorption ionization-quadrupole time of flight (MALDI-Q-TOF), MALDI-TOF-postsource decay, and database mining using ProteinProspector MS-fit and MS-tag or the PROWL ProFound search engine using a focused rodent or mammalian search. Hepatic ER proteins ER60, ERp46, ERp29, glutamate dehydrogenase, and TAP1 were shown to be more than 2-fold down-regulated, whereas α-glucosidase, P-glycoprotein, fibrinogen, protein disulfide isomerase, GRP94, and apolipoprotein E were all found to be up-regulated in the hepatic ER of the fructose-fed hamster. Seven isoforms of ER60 in the hepatic ER were all shown to be down-regulated at least 2-fold in hepatocytes from fructosefed/insulin-resistant hamsters. Implications of the differential expression of positively identified protein factors in the development of hepatic insulin resistance and lipoprotein abnormalities are discussed.

3.620 The low density lipoprotein receptor-related protein (LRP) is a novel β-secretase (BACE1) substrate
Von Armin, C.A.F. et al
J. Biol. Chem., ***280(18)***, *17777-17785 (2005)*

BACE is a transmembrane protease with β-secretase activity that cleaves the amyloid precursor protein (APP). After BACE cleavage, APP becomes a substrate for γ-secretase, leading to release of amyloid-β peptide (Aβ), which accumulates in senile plaques in Alzheimer disease. APP and BACE are co-internalized from the cell surface to early endosomes. APP is also known to interact at the cell surface and be internalized by the low density lipoprotein receptor-related protein (LRP), a multifunctional endocytic and signaling receptor. Using a new fluorescence resonance energy transfer (FRET)-based assay of protein proximity, fluorescence lifetime imaging (FLIM), and co-immunoprecipitation we demonstrate that the light chain of LRP interacts with BACE on the cell surface in association with lipid rafts. Surprisingly, the BACE-LRP interaction leads to an increase in LRP C-terminal fragment, release of secreted LRP in the media and subsequent release of the LRP intracellular domain from the membrane. Taken together, these data suggest that there is a close interaction between BACE and LRP on the cell surface, and that LRP is a novel BACE substrate.

3.621 Disturbance of sphingolipid biosynthesis abrogates the signaling of Mss4, phosphatidylinositol-4-phosphate 5-kinase, in yeast
Kobayashi, T., Takematsu, H., Yamaji, T., Hiramoto, S. and Kozutsumi, Y.
J. Biol. Chem., ***289(18)***, *18087-18094 (2005)*

The functional relationships between phosphoinositides and sphingolipids have not been well characterized to date. ISP-1/myriocin is a potent inhibitor of sphingolipid biosynthesis and induces severe growth defects in eukaryotic cells because of the sphingolipid deprivation. We characterized a novel multicopy suppressor gene of ISP-1-mediated cell death in yeast, *MSS4*. *MSS4* encodes a phosphatidylinositol-4-phosphate 5-kinase that synthesizes phosphatidylinositol (4,5)-bisphosphate ($PI4,5P_2$). We demonstrate here that ISP-1

treatment of yeast causes defects both in the activity and subcellular localization of Mss4. The effect of the Mss4 defect on the downstream signaling was examined, because interaction between the Mss4 product, $PI4,5P_2$, and the pleckstrin-homology domain of Rom2 mediates recruitment of Rom2 to the membrane, which is the crucial step for subsequent Rho1/2 activation. Indeed, failure of Rom2 recruitment was observed in ISP-1-treated cells as well as in *csg2*-deleted cells, which have reduced mannosylated inositolphosphorylceramide. These data suggested that proper sphingolipids are required for the signaling pathway involving Mss4.

3.622 Actin depolymerization transduces the strength of B-cell receptor stimulation
Hao, S. and August, A.
*Mol. Biol. Cell, **16**, 2275-2294 (2005)*

Polymerization of the actin cytoskeleton has been found to be essential for B-cell activation. We show here, however, that stimulation of BCR induces a rapid global actin depolymerization in a BCR signal strength-dependent manner, followed by polarized actin repolymerization. Depolymerization of actin enhances and blocking actin depolymerization inhibits BCR signaling, leading to altered BCR and lipid raft clustering, ERK activation, and transcription factor activation. Furthermore actin depolymerization by itself induces altered lipid raft clustering and ERK activation, suggesting that F-actin may play a role in separating lipid rafts and in setting the threshold for cellular activation.

3.623 Myosin-1a is critical for normal brush border structure and composition
Tyska, M. Et al
*Mol. Biol. Cell, **16**, 2443-2457 (2005)*

To develop our understanding of myosin-1a function in vivo, we have created a mouse line null for the *myosin-1a* gene. Myosin-1a knockout mice demonstrate no overt phenotypes at the whole animal level but exhibit significant perturbations and signs of stress at the cellular level. Among these are defects in microvillar membrane morphology, distinct changes in brush-border organization, loss of numerous cytoskeletal and membrane components from the brush border, and redistribution of intermediate filament proteins into the brush border. We also observed significant ectopic recruitment of another short-tailed class I motor, myosin-1c, into the brush border of knockout enterocytes. This latter finding, a clear demonstration of functional redundancy among vertebrate myosins-I, may account for the lack of a whole animal phenotype. Nevertheless, these results indicate that myosin-1a is a critical multifunctional component of the enterocyte, required for maintaining the normal composition and highly ordered structure of the brush border.

3.624 Cell cycle-regulated microtubeli-independent organelle division in *Cyanidioschyzon merolae*
Hishida, K., Yagisawa, F., Kuroiwa, H., Nagata, T. and Kuroiwa, T.
*Mol. Biol. Cell, **16**, 2493-2502 (2005)*

Mitochondrial and chloroplast division controls the number and morphology of organelles, but how cells regulate organelle division remains to be clarified. Here, we show that each step of mitochondrial and chloroplast division is closely associated with the cell cycle in *Cyanidioschyzon merolae*. Electron microscopy revealed direct associations between the spindle pole bodies and mitochondria, suggesting that mitochondrial distribution is physically coupled with mitosis. Interconnected organelles were fractionated under microtubule-stabilizing condition. Immunoblotting analysis revealed that the protein levels required for organelle division increased before microtubule changes upon cell division, indicating that regulation of protein expression for organelle division is distinct from that of cytokinesis. At the mitochondrial division site, dynamin stuck to one of the divided mitochondria and was spatially associated with the tip of a microtubule stretching from the other one. Inhibition of microtubule organization, proteasome activity or DNA synthesis, respectively, induced arrested cells with divided but shrunk mitochondria, with divided and segregated mitochondria, or with incomplete mitochondrial division restrained at the final severance, and repetitive chloroplast division. The results indicated that mitochondrial morphology and segregation but not division depend on microtubules and implied that the division processes of the two organelles are regulated at distinct checkpoints.

3.625 Presenilin function and γ-secretase activity
Brunkan, A.L. and Goate, A.M.
*J. Neurochem., **93**, 769-792 (2005)*

Alzheimer's disease (AD) is the most common form of dementia and is characterized pathologically by the accumulation of β-amyloid (Aβ) plaques and neurofibrillary tangles in the brain. Genetic studies of AD first highlighted the importance of the presenilins (PS). Subsequent functional studies have demonstrated that PS form the catalytic subunit of the γ-secretase complex that produces the Aβ peptide, confirming the central role of PS in AD biology. Here, we review the studies that have characterized PS function in the γ-secretase complex in *Caenorhabditis elegans*, mice and in *in vitro* cell culture systems, including studies of PS structure, PS interactions with substrates and other γ-secretase complex members, and the evidence supporting the hypothesis that PS are aspartyl proteases that are active in intramembranous proteolysis. A thorough knowledge of the mechanism of PS cleavage in the context of the γ-secretase complex will further our understanding of the molecular mechanisms that cause AD, and may allow the development of therapeutics that can alter Aβ production and modify the risk for AD.

3.626 Amphotropic murine leukaemia virus envelope protein is associated with cholesterol-rich microdomains

Beer, C., Pedersen, L. and Wirth, M.
Virology J., ***2(36)***, *1-9 (2005)*

Background
Cholesterol-rich microdomains like lipid rafts were recently identified as regions within the plasma membrane, which play an important role in the assembly and budding of different viruses, e.g., measles virus and human immunodeficiency virus. For these viruses association of newly synthesized viral proteins with lipid rafts has been shown.
Results
Here we provide evidence for the association of the envelope protein (Env) of the 4070A isolate of amphotropic murine leukaemia virus (A-MLV) with lipid rafts. Using density gradient centrifugation and immunocytochemical analyses, we show that Env co-localizes with cholesterol, ganglioside GM1 and caveolin-1 in these specific regions of the plasma membrane.
Conclusions
These results show that a large amount of A-MLV Env is associated with lipid rafts and suggest that cholesterol-rich microdomains are used as portals for the exit of A-MLV.

3.627 Role of photoreceptor-specific retinal dehydrogenase in the retinoid cycle in vivo

Maeda, A. et al
J. Biol. Chem., ***280(19)***, *18822-18832 (2005)*

The retinoid cycle is a recycling system that replenishes the 11-*cis*-retinal chromophore of rhodopsin and cone pigments. Photoreceptor-specific retinol dehydrogenase (prRDH) catalyzes reduction of all-*trans*-retinal to all-*trans*-retinol and is thought to be a key enzyme in the retinoid cycle. We disrupted mouse *prRDH* (human gene symbol *RDH8*) gene expression by targeted recombination and generated a homozygous *prRDH* knock-out (*prRDH–/–*) mouse. Histological analysis and electron microscopy of retinas from 6- to 8-week-old *prRDH–/–* mice revealed no structural differences of the photoreceptors or inner retina. For brief light exposure, absence of prRDH did not affect the rate of 11-*cis*-retinal regeneration or the decay of Meta II, the activated form of rhodopsin. Absence of prRDH, however, caused significant accumulation of all-*trans*-retinal following exposure to bright lights and delayed recovery of rod function as measured by electroretinograms and single cell recordings. Retention of all-*trans*-retinal resulted in slight overproduction of A2E, a condensation product of all-*trans*-retinal and phosphatidylethanolamine. We conclude that prRDH is an enzyme that catalyzes reduction of all-*trans*-retinal in the rod outer segment, most noticeably at higher light intensities and prolonged illumination, but is not an essential enzyme of the retinoid cycle.

3.628 Acidocacisomes – conserved from bacteria to man

Docampo, R., de Souza, W., Miranda, K., Rohloff, P. and Moreno, S.N.J.
Nature Rev. Microbiol., ***3***, *251-261 (2005)*

Recent work has shown that acidocalcisomes, which are electron-dense acidic organelles rich in calcium and polyphosphate, are the only organelles that have been conserved during evolution from prokaryotes to eukaryotes. Acidocalcisomes were first described in trypanosomatids and have been characterized in most detail in these species. Acidocalcisomes have been linked with several functions, including storage of cations and phosphorus, polyphosphate metabolism, calcium homeostasis, maintenance of intracellular pH

homeostasis and osmoregulation. Here, we review acidocalcisome ultrastructure, composition and function in different trypanosomatids and other organisms.

3.629 C18:3-GM1a induces apoptosis in Neuro2 cells: enzymatic remodeling of fatty acyl chains of glycosphingolipids
Nakagawa, T. Et al
J. Lipi. Res., ***46***, *1103-1112 (2005)*

GM1a [Galß1-3GalNAcß1-4(NeuAcα2-3)Galß1-4Glcß1-1Cer] is known to support and protect neuronal functions. However, we report that α-linolenic acid-containing GM1a (C18:3-GM1a), which was prepared using the reverse hydrolysis reaction of sphingolipid ceramide *N*-deacylase, induced apoptosis in neuronal cells. Intranucleosomal DNA fragmentation, chromatin condensation, and caspase activation, all typical features of apoptosis, were observed when mouse neuroblastoma Neuro2a cells were cultured with C18:3-GM1a but not GM1a containing stearic acid (C18:0) or oleic acid (C18:1). The phenotype of Neuro2a cells induced by C18:3-GM1a was similar to that evoked by lyso-GM1a. However, lyso-GM1a caused a complete disruption of lipid microdomains of Neuro2a cells and hemolysis of sheep erythrocytes, whereas C18:3-GM1a did neither. C18:3-GM1a, but not lyso-GM1a, was found to be abundant in lipid microdomains after the removal of loosely bound GM1a by BSA. The activation of stress-activated protein kinase/c-Jun N-terminal kinase in Neuro2a cells was observed with lyso-GM1a but not C18:3-GM1a. These results indicate that the mechanism of apoptosis induced by C18:3-GM1a is distinct from that caused by lyso-GM1a. This study also clearly shows that fatty acid composition of gangliosides significantly affected their pharmacological activities when added to the cell cultures and suggests why naturally occurring gangliosides do not possess polyunsaturated fatty acids as a major constituent.

3.630 Truncated prion protein and doppel are myelinotoxic in the absence of oligodendrocytic PrP^C
Radovanovic, I. Et al
J. Neurosci., ***25(19)***, *4879-4888 (2005)*

The cellular prion protein PrP^C confers susceptibility to transmissible spongiform encephalopathies, yet its normal function is unknown. Although PrP^C-deficient mice develop and live normally, expression of amino proximally truncated PrP^C (ΔPrP) or of its structural homolog Doppel (Dpl) causes cerebellar degeneration that is prevented by coexpression of full-length PrP^C. We now report that mice expressing ΔPrP or Dpl suffer from widespread leukoencephalopathy. Oligodendrocyte-specific expression of full-length PrP^C under control of the myelin basic protein (MBP) promoter repressed leukoencephalopathy and vastly extended survival but did not prevent cerebellar granule cell (CGC) degeneration. Conversely, neuron-specific PrP^C expression under control of the neuron-specific enolase (NSE) promoter antagonized CGC degeneration but not leukoencephalopathy. PrP^C was found in purified myelin and in cultured oligodendrocytes of both wild-type and MBP-PrP transgenic mice but not in NSE-PrP mice. These results identify white-matter damage as an extraneuronal PrP-associated pathology and suggest a previously unrecognized role of PrP^C in myelin maintenance.

3.631 Differential effect of phosphatidylethanolamine depletion on raft proteins. Further evidence for diversity of rafts in *Saccharomyces cerevisiae*
Opekarova, M., Malinska, K., Novakova, L. and Tanner, W.
Biochim. Biophys. Acta, ***1711(1)***, *87-95 (2005)*

A considerable amount of evidence supports the idea that lipid rafts are involved in many cellular processes, including protein sorting and trafficking. We show that, in this process, also a non-raft lipid, phosphatidylethanolamine (PE), has an indispensable function. The depletion of this phospholipid results in an accumulation of a typical raft-resident, the arginine transporter Can1p, in the membranes of Golgi, while the trafficking of another plasma membrane transporter, Pma1p, is interrupted at the level of the ER. Both these transporters associate with a Triton (TX-100) resistant membrane fraction before their intracellular transport is arrested in the respective organelles. The Can1p undelivered to the plasma membrane is fully active when reconstituted to a PE-containing vesicle system in vitro. We further demonstrate that, in addition to the TX-100 resistance at 4 °C, Can1p and Pma1pa exhibit different accessibility to nonyl glucoside (NG), which points to distinct intimate lipid surroundings of these two proteins. Also, at 20 °C, these two proteins are extracted by TX-100 differentially. The features above suggest that Pma1p and Can1p are associated with different compartments. This is independently supported by the observations made by confocal microscopy. In addition we show that PE is involved in the stability of Can1p–raft association.

3.632 Essential function of *Drosophila Sec6* in apical exocytosis of epithelial photoreceptor cells
Beronja, S. et al
*J. Cell Biol., **169(4)**, 635-646 (2005)*

Polarized exocytosis plays a major role in development and cell differentiation but the mechanisms that target exocytosis to specific membrane domains in animal cells are still poorly understood. We characterized *Drosophila* Sec6, a component of the exocyst complex that is believed to tether secretory vesicles to specific plasma membrane sites. *sec6* mutations cause cell lethality and disrupt plasma membrane growth. In developing photoreceptor cells (PRCs), Sec6 but not Sec5 or Sec8 shows accumulation at adherens junctions. In late PRCs, Sec6, Sec5, and Sec8 colocalize at the rhabdomere, the light sensing subdomain of the apical membrane. PRCs with reduced Sec6 function accumulate secretory vesicles and fail to transport proteins to the rhabdomere, but show normal localization of proteins to the apical stalk membrane and the basolateral membrane. Furthermore, we show that Rab11 forms a complex with Sec5 and that Sec5 interacts with Sec6 suggesting that the exocyst is a Rab11 effector that facilitates protein transport to the apical rhabdomere in *Drosophila* PRCs.

3.633 Myosin Va transports dense core secretory vesicles in pancreatic MIN6 β-cells
Varadi, A., Tsuboi, T. And Rutter, G.A.
*Mol. Biol. Cell, **16**, 2670-2680 (2005)*

The role of unconventional myosins in neuroendocrine cells is not fully understood, with involvement suggested in the movement of both secretory vesicles and mitochondria. Here, we demonstrate colocalization of myosin Va (MyoVa) with insulin in pancreatic β-cells and show that MyoVa copurifies with insulin in density gradients and with the vesicle marker phogrin-enhanced green fluorescent protein upon fluorescence-activated sorting of vesicles. By contrast, MyoVa immunoreactivity was poorly colocalized with mitochondrial or other markers. Demonstrating an important role for MyoVa in the recruitment of secretory vesicles to the cell surface, a reduction of MyoVa protein levels achieved by RNA interference caused a significant decrease in glucose- or depolarization-stimulated insulin secretion. Similarly, expression of the dominant-negative–acting globular tail domain of MyoVa decreased by ~50% the number of vesicles docked at the plasma membrane and by 87% the number of depolarization-stimulated exocytotic events detected by total internal reflection fluorescence microscopy. We conclude that MyoVa-driven movements of vesicles along the cortical actin network are essential for the terminal stages of regulated exocytosis in β-cells.

3.634 Acute and chronic changes in cholesterol modulate Na-P_i cotransport activity in OK cells
Breusegem, S.Y. et al
*Am. J. Physiol., **289**, FF154-F165 (2005)*

We previously showed an inverse correlation between membrane cholesterol content and Na-P_i cotransport activity during the aging process and adaptation to alterations in dietary P_i in the rat (Levi M, Jameson DM, and van der Meer BW. *Am J Physiol Renal Fluid Electrolyte Physiol* 256: F85–F94, 1989). The purpose of the present study was to determine whether alterations in cholesterol content per se modulate Na-P_i cotransport activity and apical membrane Na-P_i protein expression in opossum kidney (OK) cells. Acute cholesterol depletion achieved with β-methyl cyclodextrin (β-MCD) resulted in a significant increase in Na-P_i cotransport activity accompanied by a moderate increase in apical membrane Na-P_i protein abundance and no alteration of total cellular Na-P_i protein abundance. Conversely, acute cholesterol enrichment achieved with β-MCD/cholesterol resulted in a significant decrease in Na-P_i cotransport activity with a moderate decrease in apical membrane Na-Pi protein abundance and no change of the total cellular Na-P_i protein abundance. In contrast, chronic cholesterol depletion, achieved by growing cells in lipoprotein-deficient serum (LPDS), resulted in parallel and significant increases in Na-P_i cotransport activity and apical membrane and total cellular Na-P_i protein abundance. Cholesterol depletion also resulted in a significant increase in membrane lipid fluidity and alterations in lipid microdomains as determined by laurdan fluorescence spectroscopy and imaging. Chronic cholesterol enrichment, achieved by growing cells in LPDS followed by loading with low-density lipoprotein, resulted in parallel and significant decreases in Na-P_i cotransport activity and apical membrane and total cellular Na-P_i protein abundance. Our results indicate that in OK cells acute and chronic alterations in cholesterol content per se modulate Na-P_i cotransport activity by diverse mechanisms that also include significant interactions of Na-P_i protein with lipid microdomains.

3.635 Water and solute permeability of rat lung caveolae: high permeabilities explained by acyl chain unsaturation

Hill, W.G., Almasri, E., Ruiz, W.G., Apodaca, G. and Zeidel, M.L.
*Am. J. Physiol., **289**, C33-C41 (2005)*

Caveolae are invaginated membrane structures with high levels of cholesterol, sphingomyelin, and caveolin protein that are predicted to exist as liquid-ordered domains with low water permeability. We isolated a caveolae-enriched membrane fraction without detergents from rat lung and characterized its permeability properties to nonelectrolytes and protons. Membrane permeability to water was $2.85 \pm 0.41 \times 10^{-3}$ cm/s, a value 5–10 times higher than expected based on comparisons with other cholesterol and sphingolipid-enriched membranes. Permeabilities to urea, ammonia, and protons were measured and found to be moderately high for urea and ammonia at $8.85 \pm 2.40 \times 10^{-7}$ and $6.84 \pm 1.03 \times 10^{-2}$ respectively and high for protons at $8.84 \pm 3.06 \times 10^{-2}$ cm/s. To examine whether caveolin or other integral membrane proteins were responsible for high permeabilities, liposomes designed to mimic the lipids of the inner and outer leaflets of the caveolar membrane were made. Osmotic water permeability to both liposome compositions were determined and a combined inner/outer leaflet water permeability was calculated and found to be close to that of native caveolae at $1.58 \pm 1.1 \times 10^{-3}$ cm/s. In caveolae, activation energy for water flux was high (19.4 kcal/mol) and water permeability was not inhibited by $HgCl_2$; however, aquaporin 1 was detectable by immunoblotting. Immunostaining of rat lung with AQP1 and caveolin antisera revealed very low levels of colocalization. We conclude that aquaporin water channels do not contribute significantly to the observed water flux and that caveolae have relatively high water and solute permeabilities due to the high degree of unsaturation in their fatty acyl chains.

3.636 Use of phospho-specific antibodies to determine the phosphorylation of endogenous Na^+/H^+ exchanger NHE3 at PKA consensus sites

Kocinsky, H.S. et al
*Am. J. Physiol., **289**, F249-F258 (2005)*

Transfection studies using mutant constructs have implicated one or both protein kinase A (PKA) consensus phosphorylation sites [serines 552 and 605 in rat Na^+/H^+ exchanger type 3 (NHE3)] as critical for mediating inhibition of NHE3 in response to several stimuli including dopamine. However, whether one or both of these sites is actually phosphorylated in endogenous NHE3 in proximal tubule cells is unknown. The purpose of this study was to generate phosphospecific antibodies so that the state of phosphorylation of these serine residues in endogenous NHE3 could be assessed in vitro and in vivo. To this end, polyclonal and monoclonal phosphospecific peptide antibodies were generated against each PKA consensus site. Phosphospecificity was established by ELISA and Western blot assays. We then used these antibodies in vitro to evaluate the effect of dopamine on phosphorylation of the corresponding PKA sites (serines 560 and 613) in NHE3 endogenously expressed in opossum kidney cells. Baseline phosphorylation of both sites was detected that was significantly increased by dopamine. Next, we determined the baseline phosphorylation state of each serine in rat kidney NHE3 in vivo. We found that serine 552 of NHE3 is phosphorylated to a much greater extent than serine 605 at baseline in vivo. Moreover, we detected a distinct subcellular localization for NHE3 phosphorylated at serine 552 compared with total NHE3. Specifically, NHE3 phosphorylated at serine 552 localized to the coated pit region of the brush-border membrane, where NHE3 is inactive, while total NHE3 was found throughout the brush-border membrane. These findings strongly suggest that phosphorylation of NHE3 plays a role in its subcellular trafficking in vivo. In conclusion, we successfully generated phosphospecific antibodies that should be useful to assess the phosphorylation of endogenous NHE3 at its two PKA consensus sites under a variety of physiological conditions in vitro and in vivo.

3.637 Interaction of presenilins with FKBP38 promotes apoptosis by reducing mitochondrial Bcl-2

Wang, H-Q. et al
*Hum. Mol. Genet., **14(13)**, 1889-1902 (2005)*

Presenilins 1 and 2 (PS1/2), causative molecules for familial Alzheimer's disease (FAD), are multipass transmembrane proteins localized predominantly in the endoplasmic reticulum (ER) and Golgi apparatus. Heteromeric protein complexes containing PS1/2 are thought to participate in several functions, including intramembrane proteolysis mediated by their γ-secretase activities. Previous studies have shown that PS1/2 are also involved in the regulation of apoptotic cell death, although the underlying mechanism remains unknown. Here, we demonstrate that FKBP38, an immunophilin family member residing in the

mitochondrial membrane, is an authentic PS1/2-interacting protein. PS1/2 and FKBP38 form macromolecular complexes together with anti-apoptotic Bcl-2. PS1/2 promote the degradation of FKBP38 and Bcl-2 and sequester these proteins in the ER/Golgi compartments, thereby inhibiting FKBP38-mediated mitochondrial targeting of Bcl-2 via a γ-secretase-independent mechanism. Thus, PS1/2 increase the susceptibility to apoptosis by antagonizing the anti-apoptotic function of FKBP38. In contrast, C-terminal fragments of caspase-processed PS1/2 redistribute Bcl-2 to the mitochondria by abrogating the activity of full-length PS1/2, resulting in a dominant-negative anti-apoptotic effect. In cultured cells and mutant PS1-knockin mice brains, FAD-linked PS1/2 mutants enhance the pro-apoptotic activity by causing a more efficient reduction in mitochondrial Bcl-2 than wild-type PS1/2. These results suggest a novel molecular mechanism for the regulation of mitochondria-mediated apoptosis by competition between PS1/2 and FKBP38 for subcellular targeting of Bcl-2. Excessive pro-apoptotic activity of PS1/2 may play a role in the pathogenesis of FAD.

3.638 Analysis of proteome bound to D-loop region of mitochondrial DNA by DNA-linked affinity chromatography and reverse-phase liquid chromatography/tandem mass spectrometry
Choi, Y-S., Ryu, B-K., Min, H-K., Lee, S-W. and Pak, Y.K.
Ann. N.Y. Acad. Sci., ***1042***, *88-100 (2005)*

Mitochondrial dysfunction has been suggested as a causal factor for insulin resistance and diabetes. Previously we have shown a decrease of mitochondrial DNA (mtDNA) content in tissues of diabetic patients. The mitochondrial proteins, which regulate the mitochondrial biogensis, including transcription and replication of mtDNA, are encoded by nuclear DNA. Despite the potential function of the proteins bound to the D-loop region of mtDNA in regulating mtDNA transcription/replication, only a few proteins are known to bind the D-loop region of mtDNA. The functional association of these known proteins with insulin resistance is weak. In this study, we applied proteomic analysis to identify a group of proteins (proteome) that physically bind to D-loop DNA of mtDNA. We amplified D-loop DNA (1.1 kb) by PCR and conjugated the PCR fragments to CNBr-activated sepharose. Mitochondria fractions were isolated by both differential centrifugation and **Optiprep**-gradient ultracentrifugation. The D-loop DNA binding proteome fractions were enriched via this affinity chromatography and analyzed by SDS-PAGE. The proteins on the gel were transferred onto PVDF membrane and the peptide sequences of each band were subsequently analyzed by capillary reverse-phase liquid chromatography/tandem mass spectrometry (RPLC/MS/MS). We identified many D-loop DNA binding proteins, including mitochondrial transcription factor A (mtTFA, Tfam) and mitochondrial single-stranded DNA binding protein (mtSSBP) which were known to bind to mtDNA. We also report the possibility of novel D-loop binding proteins such as histone family proteins and high-mobility group proteins.

3.639 Intravesicular localization and exocytosis of α-synuclein and its aggregates
Lee, H.J., Patel, S. and Lee, S-J.
J. Neurosci., ***25(25)***, *6016-6024 (2005)*

α-Synuclein (α-syn), particularly in its aggregated forms, is implicated in the pathogenesis of Parkinson's disease and other related neurological disorders. However, the normal biology of α-syn and how it relates to the aggregation of the protein are not clearly understood. Because of the lack of the signal sequence and its predominant localization in the cytosol, α-syn is generally considered exclusively an intracellular protein. Contrary to this assumption, here, we show that a small percentage of newly synthesized α-syn is rapidly secreted from cells via unconventional, endoplasmic reticulum/Golgi-independent exocytosis. Consistent with this finding, we also demonstrate that a portion of cellular α-syn is present in the lumen of vesicles. Importantly, the intravesicular α-syn is more prone to aggregation than the cytosolic protein, and aggregated forms of α-syn are also secreted from cells. Furthermore, secretion of both monomeric and aggregated α-syn is elevated in response to proteasomal and mitochondrial dysfunction, cellular defects that are associated with Parkinson's pathogenesis. Thus, intravesicular localization and secretion are part of normal life cycle of α-syn and might also contribute to pathological function of this protein.

3.640 Analysis of human immunodeficiency virus type 1 Gag ubiquitination
Gottwein, E. And Kräusslich, H-G.
J. Virol., ***79(14)***, *9134-9144 (2005)*

Ubiquitin is important for the release of human immunodeficiency virus type 1 (HIV-1) and several other retroviruses, but the functional significance of Gag ubiquitination is unknown. To address this problem, we decided to analyze Gag ubiquitination in detail. A low percentage of the HIV-1 p6 protein has previously

been shown to be ubiquitinated, and published mutagenesis data suggested that Gag ubiquitination is largely lost upon mutation of the two lysine residues in p6. In this study, we show that Gag proteins lacking the p6 domain or the two lysine residues within p6 are ubiquitinated at levels comparable to those of the wild-type Gag protein. We detected monoubiquitinated forms of the matrix (MA), capsid (CA), and nucleocapsid (NC) proteins in mature virus preparations. Protease digestion of Gag polyproteins extracted from immature virions indicated that ubiquitinated MA, CA, and possibly NC are as abundant as ubiquitinated p6. The HIV-1 late-domain motifs PTAP and LRSLF were not required for Gag ubiquitination, and mutation of the PTAP motif even resulted in an increase in the amount of Gag-Ub conjugates detected. Finally, at steady state, ubiquitinated Gag proteins were not enriched in either membrane-associated or virus-derived Gag fractions. In summary, these results indicate that HIV-1 Gag can be monoubiquitinated in all domains and that ubiquitination of lysine residues outside p6 may thus contribute to viral release and/or infectivity.

3.641 Hyperhomocysteinemia, a cardiac metabolic disease role of nitric oxide and the $p22^{phox}$ subunit of NADPH oxidase
Becker, J.S. et al
*Circulation, **111**, 2112-2118 (2005)*

***Background*—** Hyperhomocysteinemia (HHcy) is a reliable indicator of cardiovascular disease, in part because of the production of superoxide and scavenging of nitric oxide (NO). The present study assessed the impact of HHcy on the NO-dependent control of cardiac O_2 consumption and examined enzymatic sources of superoxide.
***Methods and Results*—** Rats and mice were fed methionine in drinking water for 5 to 9 weeks to increase plasma homocysteine, a process that did not cause significant changes in hemodynamic function. The ability of the NO agonists bradykinin and carbachol to reduce myocardial O_2 consumption in vitro was impaired by ≈40% in methionine-fed rats, and this impairment was proportional to their individual plasma homocysteine concentration. However, responses were restored in the presence of ascorbic acid, tempol, and apocynin, which inhibits NADPH oxidase assembly. Western blots showed no difference in Cu/Zn or Mn superoxide dismutase, endothelial NO synthase, or inducible NO synthase protein, but HHcy caused a 100% increase in the $p22^{phox}$ subunit of NADPH oxidase. Western blots with plasma membrane–enriched fractions of cell lysate detected elevated levels of $p22^{phox}$, $p67^{phox}$, and rac-1, which indicates increased oxidase assembly. Finally, mice lacking a functional $gp91^{phox}$ subunit of NADPH oxidase demonstrated normal NO-dependent regulation of myocardial O_2 consumption after methionine feeding.
***Conclusions*—** In HHcy, superoxide produced by NADPH oxidase reduces the ability of NO to regulate mitochondrial function in the myocardium. The severity of this effect is proportional to the increase in homocysteine.

3.642 Ceramide 1-phosphate, a mediator of phagocytosis
Hinkovska-Galcheva, V. Et al
*J. Biol. Chem., **280(28)**, 26612-26621 (2005)*

The agonist-stimulated metabolism of membrane lipids produces potent second messengers that regulate phagocytosis. We studied whether human ceramide kinase (hCERK) activity and ceramide 1-phosphate formation could lead to enhanced phagocytosis through a mechanism involving modulation of the membrane-structural order parameter. hCERK was stably transfected into COS-1 cells that were stably transfected with the $Fc\gamma$RIIA receptor. hCERK-transfected cells displayed a significant increase in phagocytic index in association with increased ceramide kinase activation and translocation to lipid rafts after activation with opsonized erythrocytes. When challenged with opsonized erythrocytes, hCERK-transfected cells increased phagocytosis by 1.5-fold compared with vector control and simultaneously increased ceramide 1-phosphate levels 2-fold compared with vector and unstimulated control cells. Control and hCERK-transfected cells were subjected to cellular fractionation. Utilizing an antibody against hCERK, we observed that CERK translocates during activation from the cytosol to a lipid raft fraction. The plasma membrane-structural order parameter of the transfectants was measured by labeling cells with Laurdan. Cells transfected with hCERK showed a higher liquid crystalline order than control cells with stimulation, conditions that are favorable for the promotion of membrane fusion at the sites of phagocytosis. The change in the structural order parameter of the lipid rafts probably contributes to phagocytosis by promoting phagosome formation.

3.643 Murine coronavirus requires lipid rafts for virus entry and cell-cell fusion but not for virus release
Choi, K.S., Aizaki, H. and Lai, M.M.

*J. Virol., **79(15)**, 9862-9871 (2005)*

Thorp and Gallagher first reported that depletion of cholesterol inhibited virus entry and cell-cell fusion of mouse hepatitis virus (MHV), suggesting the importance of lipid rafts in MHV replication (E. B. Thorp and T. M. Gallagher, J. Virol. **78:**2682-2692, 2004). However, the MHV receptor is not present in lipid rafts, and anchoring of the MHV receptor to lipid rafts did not enhance MHV infection; thus, the mechanism of lipid rafts involvement is not clear. In this study, we defined the mechanism and extent of lipid raft involvement in MHV replication. We showed that cholesterol depletion by methyl ß-cyclodextrin or filipin did not affect virus binding but reduced virus entry. Furthermore, MHV spike protein bound to nonraftraft membrane at 4°C but shifted to lipid rafts at 37°C, indicating a redistribution of membrane following virus binding. Thus, the lipid raft involvement in MHV entry occurs at a step following virus binding. We also found that the viral spike protein in the plasma membrane of the infected cells was associated with lipid rafts, whereas that in the Golgi membrane, where MHV matures, was not. Moreover, the buoyant density of the virion was not changed when MHV was produced from the cholesterol-depleted cells, suggesting that MHV does not incorporate lipid rafts into the virion. These results indicate that MHV release does not involve lipid rafts. However, MHV spike protein has an inherent ability to associate with lipid rafts. Correspondingly, cell-cell fusion induced by MHV was retarded by cholesterol depletion, consistent with the association of the spike protein with lipid rafts in the plasma membrane. These findings suggest that MHV entry requires specific interactions between the spike protein and lipid rafts, probably during the virus internalization step.

3.644 Epidermal growth factor receptors are localized to lipid rafts that contain a balance of inner and outer leaflet lipids
Pike, L.J., Han, X. and Gross, R.W.
*J. Biol. Chem., **280(29)**, 26796-26804*

The epidermal growth factor (EGF) receptor partitions into lipid rafts made using a detergent-free method, but is extracted from low density fractions by Triton X-100. By screening several detergents, we identified Brij 98 as a detergent in which the EGF receptor is retained in detergent-resistant membrane fractions. To identify the difference in lipid composition between those rafts that harbored the EGF receptor (detergent-free and Brij 98-resistant) and those that did not (Triton X-100-resistant), we used multidimensional electrospray ionization mass spectrometry to perform a lipidomics study on these three raft preparations. Although all three raft preparations were similarly enriched in cholesterol, the EGF receptor-containing rafts contained more ethanolamine glycerophospholipids and less sphingomyelin than did the non-EGF receptor-containing Triton X-100 rafts. As a result, the detergent-free and Brij 98-resistant rafts exhibited a balance of inner and outer leaflet lipids, whereas the Triton X-100 rafts contained a preponderance of outer leaflet lipids. Furthermore, in all raft preparations, the outer leaflet phospholipid species were significantly different from those in the bulk membrane, whereas the inner leaflet lipids were quite similar to those found in the bulk membrane. These findings indicate that the EGF receptor is retained only in rafts that exhibit a lipid distribution compatible with a bilayer structure and that the selection of phospholipids for inclusion into rafts occurs mainly on the outer leaflet lipids.

3.645 Light-dependent redistribution of arrestin in vertebrate rods is an energy-independent process governed by protein-protein interactions
Nair, K.S. et al
*Neuron, **46**, 555-567 (2005)*

In rod photoreceptors, arrestin localizes to the outer segment (OS) in the light and to the inner segment (IS) in the dark. Here, we demonstrate that redistribution of arrestin between these compartments can proceed in ATP-depleted photoreceptors. Translocation of transducin from the IS to the OS also does not require energy, but depletion of ATP or GTP inhibits its reverse movement. A sustained presence of activated rhodopsin is required for sequestering arrestin in the OS, and the rate of arrestin relocalization to the OS is determined by the amount and the phosphorylation status of photolyzed rhodopsin. Interaction of arrestin with microtubules is increased in the dark. Mutations that enhance arrestin-microtubule binding attenuate arrestin translocation to the OS. These results indicate that the distribution of arrestin in rods is controlled by its dynamic interactions with rhodopsin in the OS and microtubules in the IS and that its movement occurs by simple diffusion.

3.646 Role of fission yeast myosin I in organization of sterol-rich membrane domains
Takeda, T. and Chang, F.

*Current Biol., **15**, 1331-1336 (2005)*

Specialized membrane domains containing lipid rafts are thought to be important for membrane processes such as signaling and trafficking **[1 and 2].** An unconventional type I myosin has been shown to reside in lipid rafts and function to target a disaccharidase to rafts in brush borders of intestinal mammalian cells **[3].** In the fission yeast *Schizosaccharomyces pombe*, distinct sterol-rich membrane domains are formed at the cell division site and sites of polarized cell growth at cell tips **[4].** Here, we show that the sole *S. pombe* myosin I, myo1p, is required for proper organization of these membrane domains. *myo1* mutants lacking the TH1 domain exhibit a uniform distribution of sterol-rich membranes all over the plasma membrane throughout the cell cycle. These effects are independent of endocytosis because *myo1* mutants exhibit no endocytic defects. Conversely, overexpression of myo1p induces ectopic sterol-rich membrane domains. Myo1p localizes to nonmotile foci that cluster in sterol-rich plasma membrane domains and fractionates with detergent-resistant membranes. Because the myo1p TH1 domain may bind directly to acidic phospholipids, these findings suggest a model for how type I myosin contributes to the organization of specialized membrane domains.

3.647 Relationship between Alzheimer's disease clinical stage and Gq/11 in subcellular fractions of frontal cortex
Kelly, J.F. et al
*J. Neural Transm., **112**, 1049-1056 (2005)*

Alzheimer's disease (AD) is associated with impaired coupling of cell surface muscarinic cholinergic receptors to G proteins of the Gq/11 class in brain. This alteration may contribute to progression of cognitive impairment during the course of the disease. We hypothesized that increasing severity of cognitive impairment would be related to decreased levels of Gq/11 detected in key subcellular fractions made from postmortem brain tissue. In this study, we used Western blotting to determine the quantity of Gq/11α in P2, synaptic plasma membrane, cytoplasm, microsomal membrane, and lipid raft fractions prepared from superior frontal cortex gray matter of 25 patients with clinical AD confirmed by post-mortem examination. Multiple linear regression analysis that adjusted for age, sex, and education showed a linear relationship between frontal cortex synaptic plasma membrane Gq/11α levels and severity of cognitive impairment determined by Mini Mental State score measured proximate to death.

3.648 Two domains within the first putative transmembrane domain of presenilin 1 differentially influence presenilinase and γ-secretase activity
Brunkan, A.L. et al
*J. Neurochem., **94**, 1315-1328 (2005)*

Presenilins (PS) are thought to contain the active site for presenilinase endoproteolysis of PS and γ-secretase cleavage of substrates. The structural requirements for PS incorporation into the γ-secretase enzyme complex, complex stability and maturation, and appropriate presenilinase and γ-secretase activity are poorly understood. We used rescue assays to identify sequences in transmembrane domain one (TM1) of PS1 required to support presenilinase and γ-secretase activities. Swap mutations identified an N-terminal TM1 domain that is important for γ-secretase activity only and a C-terminal TM1 domain that is essential for both presenilinase and γ-secretase activities. Exchange of residues 95–98 of PS1 (sw95–98) completely abolishes both activities while the familial Alzheimer's disease mutation V96F significantly inhibits both activities. Reversion of residue 96 back to valine in the sw95–98 mutant rescues PS function, identifying V96 as the critical residue in this region. The TM1 mutants do not bind to an aspartyl protease transition state analog γ-secretase inhibitor, indicating a conformational change induced by the mutations that abrogates catalytic activity. TM1 mutant PS1 molecules retain the ability to interact with γ-secretase substrates and γ-secretase complex members, although Nicastrin stability is decreased by the presence of these mutants. γ-Secretase complexes that contain V96F mutant PS1 molecules display a partial loss of function for γ-secretase that alters the ratio of amyloid-β peptide species produced, leading to the amyloid-β peptide aggregation that causes familial Alzheimer's disease.

3.649 Effects of a mosquitocidal toxin on a mammalian epithelial cell line expressing its target receptor
Pauchet, Y. Et al
*Cell. Microbiol., **7(9)**, 1335-1344 (2005)*

The spread of diseases transmitted by *Anopheles* and *Culex* mosquitoes, such as malaria and West Nile fever, is a growing concern for human health. *Bacillus sphaericus* binary toxin (Bin) is one of the few

available bioinsecticides able to control populations of these mosquitoes efficiently. We previously showed that Bin binds to Cpm1, an α-glucosidase located on the apical side of *Culex* larval midgut epithelium. We analysed the effects of Bin by expressing a construct encoding Cpm1 in the mammalian epithelial MDCK cell line. Cpm1 is targeted to the apical side of polarized MDCK, where it is anchored by glycosylphosphatidylinositol (GPI) and displays α-glucosidase activity. Bin bound to transfected cells and induced a non-specific current presumably related to the opening of pores. The formation of these pores may be related to the location of the toxin/receptor complex in lipid raft microdomains. Finally, Bin promoted the time-dependent appearance of intracytoplasmic vacuoles but did not drive cell lysis. Thus, the dual functionality (enzyme/toxin receptor) of Cpm1 is fully conserved in MDCK cells and Cpm1 is an essential target protein for Bin cytotoxicity in *Culex* mosquitoes.

3.650 The golgin lava lamp mediates dynein-based Golgi movements during *Drosophila* cellularization
Papoulas, O., Hays, T.S. and Sisson, J.C.
*Nature Cell Biol., **7(8)**, 612-618 (2005)*

Drosophila melanogaster cellularization is a dramatic form of cytokinesis in which a membrane furrow simultaneously encapsulates thousands of cortical nuclei of the syncytial embryo to generate a polarized cell layer. Formation of this cleavage furrow depends on Golgi-based secretion and microtubules[1, 2, 3]. During cellularization, specific Golgi move along microtubules, first to sites of furrow formation and later to accumulate within the apical cytoplasm of the newly forming cells[3]. Here we show that Golgi movements and furrow formation depend on cytoplasmic dynein. Furthermore, we demonstrate that Lava lamp (Lva), a golgin protein that is required for cellularization, specifically associates with dynein, dynactin, cytoplasmic linker protein-190 (CLIP-190) and Golgi spectrin, and is required for the dynein-dependent targeting of the secretory machinery. The Lva domains that bind these microtubule-dependent motility factors inhibit Golgi movement and cellularization in a live embryo injection assay. Our results provide new evidence that golgins promote dynein-based motility of Golgi membranes.

3.651 Functional role of the AAA peroxins in dislocation of the cycling PTS1 receptor back to the cytosol
Platta, H.W., Grunau, S., Rosenkrantz, K., Girzalsky, W. and Erdmann, R.
*Nature Cell Biol., **7(8)**, 817-822 (2005)*

Peroxisomal import receptors bind their cargo proteins in the cytosol and target them to docking and translocation machinery at the peroxisomal membrane (reviewed in ref. 1). The receptors release the cargo proteins into the peroxisomal lumen and, according to the model of cycling receptors, they are supposed to shuttle back to the cytosol. This shuttling of the receptors has been assigned to peroxins including the AAA peroxins Pex1p and Pex6p, as well as the ubiquitin-conjugating enzyme Pex4p (reviewed in ref. 2). One possible target for Pex4p is the PTS1 receptor Pex5p, which has recently been shown to be ubiquitinated[3, 4, 5]. Pex1p and Pex6p are both cytosolic and membrane-associated AAA ATPases of the peroxisomal protein import machinery, the exact function of which is still unknown. Here we demonstrate that the AAA peroxins mediate the ATP-dependent dislocation of the peroxisomal targeting signal-1 (PTS1) receptor from the peroxisomal membrane to the cytosol.

3.652 Exogenous nitric oxide reduces glucose transporters translocation and lactate production in ischemic myocardium in vivo
Lei, B. Et al
*PNAS, **102**, 6966-6971 (2005)*

Nitric oxide (NO) inhibits myocardial glucose transport and metabolism, although the underlying mechanism(s) and functional consequences of this effect are not clearly understood. We tested the hypothesis that NO inhibits the activation of AMP-activated protein kinase (AMPK) and translocation of cardiac glucose transporters (GLUTs; GLUT-4) and reduces lactate production. Ischemia was induced in open-chest dogs by a 66% flow reduction in the left anterior descending coronary artery (LAD). During ischemia, dogs were untreated (control) or treated by direct LAD infusion of (*i*) nitroglycerin (NTG) (0.5 $\mu g \cdot kg^{-1} \cdot min^{-1}$); (*ii*) 8-Br-cGMP (50 $\mu g \cdot kg^{-1} \cdot min^{-1}$); or (*iii*) NO synthase inhibitor L-nitro-argininemethylester (40 $\mu g \cdot kg^{-1} \cdot min^{-1}$; $n = 9$ per group). Cardiac substrate oxidation was measured with isotopic tracers. There were no differences in myocardial blood flow or oxygen delivery among groups; however, at 45 min of ischemia, the activation of AMPK was significantly less in NTG (77 ± 12% vs. nonischemic myocardium) and 8-Br-cGMP (104 ± 13%), compared with control (167 ± 17%). Similarly, GLUT-4 translocation was significantly reduced in NTG (74 ± 7%) and 8-Br-cGMP (120 ± 11%), compared with control (165 ± 17%). Glucose uptake and lactate output were 30% and 60% lower in NTG

compared with control. Inhibition of NO synthesis stimulated glucose oxidation (67% increase compared with control) but did not affect AMPK phosphorylation, GLUT-4 translocation and glucose uptake. Contractile function in the ischemic region was significantly improved by NTG and L-nitro-argininemethylester. In conclusion, in ischemic myocardium an NO donor inhibits glucose uptake and lactate production via a reduction in AMPK stimulation of GLUT-4 translocation, revealing a mechanism of metabolic modulation and myocardial protection activated by NO donors.

3.653 Role of membrane microdomains in PTH-mediated down-regulation of NaPi-Iia in opossum kidney cells

Nashiki, K. Et al

*Kidney Int., **68**, 1137-1147 (2005)*

Background. Parathyroid hormone (PTH) rapidly down-regulates type IIa sodium-dependent phosphate transporter (NaPi-IIa) via an endocytic pathway. Since the relationship between PTH signaling and NaPi-IIa endocytosis has not been explored, we investigated the role of membrane microdomains in this process.
Methods. We examined the submembrane localization of NaPi-IIa in opossum kidney (OK-N2) cells that stably expressed human NaPi-IIa, and searched for a PTH-induced specific phosphorylating substrate on their membrane microdomains by immunoblotting with specific antibody against phospho substrates of protein kinases.
Results. We found that NaPi-IIa was primarily localized in low-density membrane (LDM) domains of the plasma membrane; PTH reduced the levels of immunoreactive NaPi-IIa in these domains. Furthermore, PTH activated both protein kinase A (PKA) and protein kinase Cα (PKCa) and increased the phosphorylation of 250 kD and 80 kD substrates; this latter substrate was identified as ezrin, which a member of the ezrin-radixin-moesin (ERM) protein family. In response to PTH, ezrin was phosphorylated by both PKA and PKC. Dominant negative ezrin blocked the reduction in NaPi-IIa expression in the LDM domains that was induced by PTH.
Conclusion. These data suggest that NaPi-IIa and PTH-induced phosphorylated proteins that include ezrin are compartmentalized in LDM microdomains. This compartmentalization may play an important role in the down-regulation of NaPi-IIa via endocytosis.

3.654 B-cell receptor translocation to lipid rafts and associated signaling differ between prognostically important subgroups of chronic lymphocytic leukemia

Alsup, D.J. et al

*Cancer Res., **65(16)**, 7328-7337 (2005)*

Chronic lymphocytic leukemia (CLL) is a highly heterogeneous disease in which interaction of the malignant cells with antigen is thought to play a key role. Individual CLL-cell clones markedly differ in their ability to respond to B-cell receptor ligation, but the mechanism underlying the frequent hyporesponsiveness is incompletely understood. Our aim was to further clarify the extent and cause of the B-cell receptor signaling abnormality in CLL and to assign pathophysiologic relevance to the presence or absence of B-cell receptor responsiveness. We show that extracellular signal-regulated kinase-2 phosphorylation, intracellular Ca^{2+} increases, CD79a phosphorylation, and translocation of the B-cell receptor to lipid rafts in response to ligation with anti–immunoglobulin M (as a surrogate for antigen) are features of CLL cells with relatively unmutated *VH* genes (<5% deviation from germ line) and a poor prognosis. B-cell receptor stimulation in these cases also promoted cell survival. In clones with mutated *VH* genes (>5% deviation from germ line), surface immunoglobulin M ligation failed to induce receptor translocation to rafts or to prolong cell survival. This failure of receptor translocation observed in mutated CLL cells was associated with the constitutive exclusion of the B-cell receptor from rafts by a mechanism involving src-dependent interactions between the B-cell receptor and the actin cytoskeleton. We conclude that exposure to antigen promotes the survival of unmutated CLL clones, contributing to the poor prognosis of this group. In contrast, hyporesponsive mutated CLL clones may have developed into a stage where continuous exposure to antigen results in relative tolerance to antigenic stimulation mediated by the exclusion of the B-cell receptor from lipid rafts.

3.655 Overexpression of OSBP-related protein 2 (ORP2) induces changes in cellular cholesterol metabolism and enhances endocytosis

Hynynen, R. Et al

Biochem. J., 273-283 (2005)

ORP2 [OSBP (oxysterol-binding protein)-related protein 2] belongs to the 12-member mammalian ORP gene/protein family. We characterize in the present study the effects of inducible ORP2 overexpression on cellular cholesterol metabolism in HeLa cells and compare the results with those obtained for CHO cells (Chinese-hamster ovary cells) that express ORP2 constitutively. In both cell systems, the prominent phenotype is enhancement of [^{14}C]cholesterol efflux to all extracellular acceptors, which results in a reduction of cellular free cholesterol. No change was observed in the plasma membrane cholesterol content or distribution between raft and non-raft domains upon ORP2 expression. However, elevated HMG-CoA (3-hydroxy-3-methylglutaryl-CoA) reductase activity and LDL (low-density lipoprotein) receptor expression, as well as enhanced transport of newly synthesized cholesterol to a cyclodextrin-accessible pool, suggest that the ORP2 expression stimulates transport of cholesterol out of the endoplasmic reticulum. In contrast with ORP2/CHO cells, the inducible ORP2/HeLa cells do not show down-regulation of cholesterol esterification, suggesting that this effect represents an adaptive response to long-term cholesterol depletion in the CHO cell model. Finally, we provide evidence that ORP2 binds PtdIns(3,4,5)P_3 and enhances endocytosis, phenomena that are probably interconnected. Our results suggest a function of ORP2 in both cholesterol trafficking and control of endocytic membrane transport.

3.656 Phagocytic signaling molecules in lipid rafts of COS-1 cells transfected with FcγRIIA
Mansfield, P.J., Hinkovska-Galcheva, V., Borofsky, M.S., Shayman, J.A. and Boxer, L.A.
Biochem. Biophys. Res. Comm., ***331****, 132-138 (2005)*

COS-1 cells bearing FcγRIIA were used as a model to demonstrate co-localization of several enzymes previously shown to regulate neutrophil phagocytosis. In COS-1 cells, phospholipase D (PLD) in the membrane fraction was activated during phagocytosis. PLD was found almost exclusively in lipid rafts, along with RhoA and ARF1. Protein kinase C-δ (PKCδ) and Raf-1 translocated to lipid rafts. In neutrophils, ceramide levels increase during phagocytosis, indicating that FcγRIIA engagement initiates ceramide generation. Applying this model, we transfected COS-1 cells with FcγRIIA that had been mutated in the ITAM region, rendering them unable to ingest particles. When the mutant receptors were engaged, ceramide was generated and MAPK was activated normally, thus these processes did not require actual ingestion of particles. These results indicate that signaling proteins for phagocytosis are either constitutively present in, or are recruited to, lipid rafts where they are readily available to activate one another.

3.657 Caveolin-1 is essential for activation of Rac1 and NAD(P)H oxidase after angiotensin II type 1 receptor stimulation in vascular smooth muscle cells
Zuo, L. et al
Arterioscler. Thromb. Vasc. Biol., ***25****, 1824-1830 (2005)*

Objective— Angiotensin II (Ang II) is a potent mediator of vascular hypertrophy in vascular smooth muscle cells (VSMCs). These effects are mediated through the Ang II type 1 receptor (AT_1R) and require its trafficking through caveolin-1 (Cav1)–enriched lipid rafts and reactive oxygen species (ROS) derived from Rac1-dependent NAD(P)H oxidase. The specific role(s) of Cav1 in AT_1R signaling is incompletely understood.
Methods and Results— Knockdown of Cav1 protein by small interfering RNA (siRNA) inhibits Ang II–stimulated Rac1 activation and membrane translocation, H_2O_2 production, ROS-dependent epidermal growth factor receptor (EGF-R) transactivation, and subsequent phosphorylation of Akt without affecting ROS-independent extracellular signal-regulated kinase 1/2 phosphorylation. Ang II stimulates tyrosine phosphorylation of Sos-1, a Rac–guanine nucleotide exchange factor, which is inhibited by Cav1 siRNA, demonstrating involvement of Cav1 in Rac1 activation. Detergent-free fractionation showed that EGF-Rs are found basally in Cav1-enriched lipid raft membranes and associate with Cav1. Ang II stimulates AT_1R movement into these microdomains contemporaneously with the egress of EGF-R. Both aspects of this bidirectional receptor trafficking are inhibited by Cav1 siRNA. Moreover, Cav1 siRNA inhibits Ang II–induced vascular hypertrophy.
Conclusions— Cav1 plays an essential role in AT_1R targeting into Cav1-enriched lipid rafts and Rac1 activation, which are required for proper organization of ROS-dependent Ang II signaling linked to VSMC hypertrophy.
Angiotensin II (Ang II)–induced vascular hypertrophy is dependent on caveolae/lipid rafts and reactive oxygen species (ROS) derived from NAD(P)H oxidase. Using caveolin-1 siRNA, we demonstrate that caveolin-1 plays an essential role in AT_1 receptor targeting into caveolae/lipid rafts and Rac1 activation, which are required for ROS-dependent, growth-related Ang II signaling.

3.658 Maturation of Borma virus disease virus glycoprotein
Richt, J.A. and Garten, W.
*FEBS Lett., **579**, 4751-4756 (2005)*

The maturation of Borna disease virus (BDV) glycoprotein GP was studied in regard to intracellular compartmentalization, compartmentalization signal-domains, proteolytic processing, and packaging into virus particles. Our data show that BDV-GP is (i) predominantly located in the endoplasmic reticulum (ER), (ii) partially exists in the ER already as cleaved subunits GP-N and GP-C, (iii) is directed to the ER/cis-Golgi region by its transmembrane and/or cytoplasmic domains in CD8-BDV-GP hybrid constructs and (iv) is incorporated in the virus particles as authentic BDV glycoprotein exclusively in the cleaved form decorated with N-glycans of the complex type. Downregulation of BDV-glycoproteins on the cell surface, their limited proteolytic processing, and protection of antigenic epitopes on the viral glycoproteins by host-identical N-glycans are different strategies for persistent virus infections.

3.659 PAK5 kinase is an inhibitor of MARK/Par-1, which leads to stable microtubules and dynamic actin
Matenia, D. Et al
*Mol. Biol. Cell, **16**, 4410-4422 (2005)*

MARK/Par-1 is a kinase involved in development of embryonic polarity. In neurons, MARK phosphorylates tau protein and causes its detachment from microtubules, the tracks of axonal transport. Because the target sites of MARK on tau occur at an early stage of Alzheimer neurodegeneration, we searched for interaction partners of MARK. Here we report that MARK2 is negatively regulated by PAK5, a neuronal member of the p21-activated kinase family. PAK5 suppresses the activity of MARK2 toward its target, tau protein. The inhibition requires the binding between the PAK5 and MARK2 catalytic domains, but does not require phosphorylation. In transfected Chinese hamster ovary (CHO) cells both kinases show a vesicular distribution with partial colocalization on endosomes containing AP-1/2. Although MARK2 transfected alone destabilizes microtubules and stabilizes actin stress fibers, PAK5 keeps microtubules stable through the down-regulation of MARK2 but destabilizes the F-actin network so that stress fibers and focal adhesions disappear and cells develop filopodia. The results point to an inverse relationship between actin- and microtubule-related signaling by the PAK5 and MARK2 pathways that affect both cytoskeletal networks.

3.660 The novel fission yeast protein Pal1p interacts with Hip1-related Sla2p/End4p and is involved in cellular morphogenesis
Ge, W., Chew, T.G., Wachtler, V., Naqvi, S.N. and Balasubramanian, M.K.
*Mol. Biol. Cell, **16**, 4124-4138 (2005)*

The establishment and maintenance of characteristic cellular morphologies is a fundamental property of all cells. Here we describe *Schizosaccharomyces pombe* Pal1p, a protein important for maintenance of cylindrical cellular morphology. Pal1p is a novel membrane-associated protein that localizes to the growing tips of interphase cells and to the division site in cells undergoing cytokinesis in an F-actin- and microtubule-independent manner. Cells deleted for *pal1* display morphological defects, characterized by the occurrence of spherical and pear-shaped cells with an abnormal cell wall. Pal1p physically interacts and displays overlapping localization with the Huntingtin-interacting-protein (Hip1)-related protein Sla2p/End4p, which is also required for establishment of cylindrical cellular morphology. Sla2p is important for efficient localization of Pal1p to the sites of polarized growth and appears to function upstream of Pal1p. Interestingly, spherical *pal1*Δ mutants polarize to establish a pearlike morphology before mitosis in a manner dependent on the kelch-repeat protein Tea1p and the cell cycle inhibitory kinase Wee1p. Thus, overlapping mechanisms involving Pal1p, Tea1p, and Sla2p contribute to the establishment of cylindrical cellular morphology, which is important for proper spatial regulation of cytokinesis.

3.661 Membrane rafts segregate pro- from anti-apoptotic insulin-like growth factor-I receptor signaling in colon carcinoma cells stimulated by members of the tumor necrosis factor superfamily
Remacle-Bonnet, M. et al
*Am. J. Pathol., **167(3)**, 761-773 (2005)*

In the tumor microenvironment, autocrine/paracrine loops of insulin-like growth factors (IGFs) contribute to cancer cell survival. However, we report here that IGF-I can send contradictory signals that interfere with cell death induced by different ligands of the tumor necrosis factor (TNF) superfamily. IGF-I protected human colon carcinoma cells from TNF-α-induced apoptosis, but it enhanced the apoptotic

response to anti-Fas antibody and TNF-related apoptosis inducing ligand stimulation. This proapoptotic effect of IGF-I, observed in several but not all tested colon cancer cell lines, was mediated via the phosphatidylinositol 3'-kinase (PI3K)/Akt pathway. Furthermore, IGF-I receptors (IGF-IR) were located in and out of membrane lipid rafts and were tyrosine autophosphorylated in response to IGF-I. However, disruption of rafts by acute cholesterol depletion shifted IGF-IR to non-raft domains, abolished the IGF-I-mediated proapoptotic effect, and inhibited the IGF-I-dependent IRS-1 and Akt recruitment into and phosphorylation/activation within lipid rafts. Replenishing cell membranes with cholesterol reversed these effects. Activation of extracellular-regulated kinase-1/2 and p38 mitogen-activated protein kinase, which convey the IGF-I anti-apoptotic effect, occurred independently of lipid rafts. Thus, we propose that segregation of IGF-IR in and out of lipid rafts may dynamically regulate the pro- and anti-apoptotic effects of IGF-I on apoptosis induced by TNF superfamily members.

3.662 The actin cytoskeleton differentially regulates platelet α-granule and dense-granule secretion
Flaumenahft, R. Et al
*Blood, **105(10)**, 3879-3887 (2005)*

Stimulation of platelets with strong agonists results in centralization of cytoplasmic organelles and secretion of granules. These observations have led to the supposition that cytoskeletal contraction facilitates granule release by promoting the interaction of granules with one another and with membranes of the open canalicular system. Yet, the influence of the actin cytoskeleton in controlling the membrane fusion events that mediate granule secretion remains largely unknown. To evaluate the role of the actin cytoskeleton in platelet granule secretion, we have assessed the effects of latrunculin A and cytochalasin E on granule secretion. Exposure of platelets to low concentrations of these reagents resulted in acceleration and augmentation of agonist-induced α-granule secretion with comparatively modest effects on dense granule secretion. In contrast, exposure of platelets to high concentrations of latrunculin A inhibited agonist-induced α-granule secretion but stimulated dense granule secretion. Incubation of permeabilized platelets with low concentrations of latrunculin A primed platelets for Ca^{2+}- or guanosine triphosphate (GTP)-γ-S-induced α-granule secretion. Latrunculin A-dependent α-granule secretion was inhibited by antibodies directed at vesicle-associated membrane protein (VAMP), demonstrating that latrunculin A supports soluble *N*-ethylmaleimide-sensitive factor attachment protein receptor (SNARE) protein-dependent membrane fusion. These results indicate that the actin cytoskeleton interferes with platelet exocytosis and differentially regulates α-granule and dense granule secretion.

3.663 Plant and animal homeodomains use convergent mechanisms for intercellular transfer
Tasetto, M., Maizel, A., Osorio, J. and Joliot. A.
*EMBO Reports, **6(9)**, 885-890 (2005)*

Homeoproteins are defined by the structure of their DNA-binding domain, the homeodomain. Intercellular transfer of homeoprotein was observed *ex vivo* between animal cells and *in vivo* in higher plants. In the latter case, transfer is through intercytoplasmic channels that connect plant cells, but these do not exist in animals. Here, we show that the homeodomain of KNOTTED1, a maize homeoprotein, is transferred between animal cells and that a mutation in the homeodomain blocking the intercellular transfer of KNOTTED1 in plants also inhibits the transfer of the KNOTTED1 homeodomain in animal cells. This mutation decreases nuclear addressing, and its effect on nuclear import and intercellular transfer is reverted by the addition of an ectopic nuclear localization signal. We propose that, despite evolutionary distance and the differences in multicellular organization, similar mechanisms are at work for intercellular transfer of homeoprotein in plants and animals. Furthermore, our results suggest that, at least in animals, homeodomain secretion requires passage through the nucleus.

3.664 Purification of neuronal inclusions of patients with Huntington's disease reveals a broad range of N-terminal fragments of expanded huntingtin and insoluble polymers
Hoffner, G., Island, M-L. and Djian, P.
*J. Neurochem., **95**, 125-136 (2005)*

Huntington's disease resulting from huntingtin containing an expanded polyglutamine is associated with aggregates largely confined to neuronal inclusions, and with neuronal death. Inclusions are thought to originate from discrete N-terminal fragments of expanded huntingtin produced by specific endopeptidases. We have now purified the neuronal inclusions of Huntington's disease brain. When incubated in concentrated formic acid, purified inclusions release a polymer, an oligomer and a broad range of N-

terminal fragments of expanded huntingtin. The fragments and the polymeric forms are linked to each other by non-covalent bonds as they are both released by formic acid, whereas the polymeric forms themselves are presumably stabilized by covalent bonds, as they are resistant to formic acid. We also demonstrate the presence in affected areas of the brain but not in unaffected areas of a broad range of soluble N-terminal fragments of expanded huntingtin not yet associated with the inclusions and which are likely to be the precursors of the inclusions. Fragmentation of expanded huntingtin in Huntington's disease must result from the operation of multiple proteolytic activities with little specificity and not from that of a specific endopeptidase; subsequent aggregation of the fragments by covalent and non-covalent bonds leads to the formation of the inclusions.

3.665 Neuronal sorting protein-related receptor sorLA/LR11 regulates processing of the amyloid precursor protein
Andersen, O.M. et al
*PNAS, **102(38)**, 13461-13466 (2005)*

sorLA (sorting protein-related receptor) is a type-1 membrane protein of unknown function that is expressed in neurons. Its homology to sorting receptors that shuttle between the plasma membrane, endosomes, and the Golgi suggests a related function in neuronal trafficking processes. Because expression of sorLA is reduced in the brain of patients with Alzheimer's disease (AD), we tested involvement of this receptor in intracellular transport and processing of the amyloid precursor protein (APP) to the amyloid β-peptide (Aβ), the principal component of senile plaques. We demonstrate that sorLA interacts with APP *in vitro* and in living cells and that both proteins colocalize in endosomal and Golgi compartments. Overexpression of sorLA in neurons causes redistribution of APP to the Golgi and decreased processing to Aβ, whereas ablation of sorLA expression in knockout mice results in increased levels of Aβ in the brain similar to the situation in AD patients. Thus, sorLA acts as a sorting receptor that protects APP from processing into Aβ and thereby reduces the burden of amyloidogenic peptide formation. Consequently, reduced receptor expression in the human brain may increase Aβ production and plaque formation and promote spontaneous AD.

3.666 Subcellular localization of iron regulatory proteins to Golgi and ER membranes
Patton, S.M., Pinero, D.J., Surguladze, N., Beard, J. and Connor, J.R.
*J. Cell Sci., **118**, 4365-4373 (2005)*

Interaction between iron regulatory proteins and iron responsive elements on certain mRNAs is at the core of regulation of intracellular iron homeostasis. Previous results suggested that in cultured cells iron regulatory proteins (IRPs) exist in cytosolic and microsomal subcellular locations and that this distribution is affected by cellular iron status. In this study, we tested the hypothesis that the membrane-associated fractions of iron regulatory proteins are specifically in the endoplasmic reticulum and Golgi membranes. Confocal microscopy revealed that IRP1 could be co-localized to the endoplasmic reticulum and the Golgi apparatus. To examine the intracellular distribution of IRPs biochemically, we used rats fed normal or iron-deficient diets. As expected, the IRPs were found predominantly in the cytosolic fraction. However, subfractionation of crude microsomal preparations revealed IRP1 in the Golgi apparatus. In animals fed an iron-deficient diet, IRP1 was found in the Golgi apparatus and the endoplasmic reticulum. To identify the mechanisms and factors involved in the localization of iron regulatory proteins in the cytosol and membrane fractions, cells were treated with a phorbol ester, a protein kinase C inhibitor (chelerythrine), hydrogen peroxide, interleukin-1ß, and 1,2-bis-(o-aminophenoxy)-ethane-*N,N,-N'N'*-tetraacetic acid tetraacetoxy-methyl ester. The results indicate that iron-regulatory-protein-binding activity in the membrane fraction can be altered by cell stress or iron status and that phosphorylation plays a role in the translocation. As a result of this study we propose a novel model for intracellular distribution of IRPs and identify differences between the two iron regulatory proteins.

3.667 LRP1B functions as a receptor for pseudomonas exotoxin
Pastrana, D.V., Hanson, A.J., Knisely, J., Bu, G. and FitzGerald, D.J.
*Biochim. Biophys. Acta, **1741**, 234-239 (2005)*

Pseudomonas aeruginosa is an opportunistic pathogen that produces several virulence factors, among them Pseudomonas Exotoxin A (PE). Previously, low-density lipoprotein receptor-related protein 1 (LRP1) was shown to be the primary receptor for PE. In this report, we show that a close family member, LRP1B, can also function as a receptor.

3.668 ***Helicobacter pylori*** **VacA cytotoxin: a probe for a clathrin-independent and Cdc42-dependent pinocytic pathway routed to late endosomes**
Gauthier, N.C. et al
*Mol. Biol. Cell, **16**, 4852-4866 (2005)*

The vacuolating cytotoxin VacA is a major virulence factor of *Helicobacter pylori*, a bacterium responsible for gastroduodenal ulcers and cancer. VacA associates with lipid rafts, is endocytosed, and reaches the late endocytic compartment where it induces vacuolation. We have investigated the endocytic and intracellular trafficking pathways used by VacA, in HeLa and gastric AGS cells. We report here that VacA was first bound to plasma-membrane domains localized above F-actin structures that were controlled by the Rac1 GTPase. VacA was subsequently pinocytosed by a clathrin-independent mechanism into cell peripheral early endocytic compartments lacking caveolin 1, the Rab5 effector early endosomes antigen-1 (EEA1) and transferrin. These compartments took up fluid-phase (as evidenced by the accumulation of fluorescent dextran) and glycosylphosphatidylinositol-anchored proteins (GPI-APs). VacA pinocytosis was controlled by Cdc42 and did not require cellular tyrosine kinases, dynamin 2, ADP-ribosylating factor 6, or RhoA GTPase activities. VacA was subsequently routed to EEA1-sorting endosomes and then sorted to late endosomes. During all these different endocytic steps, VacA was continuously associated with detergent resistant membrane domains. From these results we propose that VacA might be a valuable probe to study raft-associated molecules, pinocytosed by a clathrin-independent mechanism, and routed to the degradative compartment.

3.669 **Regulation of sphingosine 1-phosphate-induced endothelial cytoskeletal rearrangement and barrier enhancement by SIP_1 receptor, PI3 kinase, Tiam1/Rac1, and α-actinin**
Singleton, P.A., Dudek, S.M., Chiang, E.T. and Garcia, J.G.N.
*FASEB J., **19**, 1646-1656 (2005)*

Endothelial cell (EC) barrier dysfunction results in increased vascular permeability observed in inflammation, tumor angiogenesis, and atherosclerosis. The platelet-derived phospholipid sphingosine-1-phosphate (S1P) decreases EC permeability in vitro and in vivo and thus has obvious therapeutic potential. We examined S1P-mediated human pulmonary artery EC signaling and barrier regulation in caveolin-enriched microdomains (CEM). Immunoblotting from S1P-treated EC revealed S1P-mediated rapid recruitment (1 μM, 5 min) to CEMs of the S1P receptors $S1P_1$ and $S1P_3$, p110 PI3 kinase α and ß catalytic subunits, the Rac1 GEF, Tiam1, and α-actinin isoforms 1 and 4. Immunoprecipitated p110 PI3 kinase catalytic subunits from S1P-treated EC exhibited PIP_3 production in CEMs. Immunoprecipitation of S1P receptors from CEM fractions revealed complexes containing Tiam1 and $S1P_1$. PI3 kinase inhibition (LY294002) attenuated S1P-induced Tiam1 association with $S1P_1$, Tiam1/Rac1 activation, α-actinin-1/4 recruitment, and EC barrier enhancement. Silencing of either $S1P_1$ or Tiam1 expression resulted in the loss of S1P-mediated Rac1 activation and α-actinin-1/4 recruitment to CEM. Finally, silencing $S1P_1$, Tiam1, or both α-actinin isoforms 1/4 inhibits S1P-induced cortical F-actin rearrangement and S1P-mediated barrier enhancement. Taken together, these results suggest that S1P-induced recruitment of $S1P_1$ to CEM fractions promotes PI3 kinase-mediated Tiam1/Rac1 activation required for α-actinin-1/4-regulated cortical actin rearrangement and EC barrier enhancement.—Singleton, P. A., Dudek, S. M., Chiang, E. T., Garcia, J. G. N. Regulation of sphingosine 1-phosphate-induced endothelial cytoskeletal rearrangement and barrier enhancement by $S1P_1$ receptor, PI3 kinase, Tiam1/Rac1 and α-actinin.

3.670 **Centriolin anchoring of exocyst and SNARE complexes at the midbody is required for secretory-vesicle-mediated abscission**
Gromley, A. et al
*Cell, **123**, 75-87 (2005)*

The terminal step in cytokinesis, called abscission, requires resolution of the membrane connection between two prospective daughter cells. Our previous studies demonstrated that the coiled-coil protein centriolin localized to the midbody during cytokinesis and was required for abscission. Here we show that centriolin interacts with proteins of vesicle-targeting exocyst complexes and vesicle-fusion SNARE complexes. These complexes require centriolin for localization to a unique midbody-ring structure, and disruption of either complex inhibits abscission. Exocyst disruption induces accumulation of v-SNARE-containing vesicles at the midbody ring. In control cells, these v-SNARE vesicles colocalize with a GFP-

tagged secreted polypeptide. The vesicles move to the midbody ring asymmetrically from one prospective daughter cell; the GFP signal is rapidly lost, suggesting membrane fusion; and subsequently the cell cleaves at the site of vesicle delivery/fusion. We propose that centriolin anchors protein complexes required for vesicle targeting and fusion and integrates membrane-vesicle fusion with abscission.

3.671 Identification of AQP5 in lipid rafts and its translocation to apical membranes by activation of M_3 mAChRs in interlobular ducts of rat parotid gland
Ishikawa, Y. Et al
*Am. J. Physiol Cell Physiol., **289**, C1303-C1311 (2005)*

Aquaporin-5 (AQP5), an apical plasma membrane (APM) water channel in salivary glands, lacrimal glands, and airway epithelium, has an important role in fluid secretion. M_3 muscarinic acetylcholine receptor (mAChR)-induced changes in AQP5 localization in rat parotid glands were investigated with immunofluorescence or immunoelectron microscopy, detergent solubility, and gradient density floatation assays. Confocal microscopy revealed AQP5 localization in intracellular vesicles of interlobular duct cells in rat parotid glands and AQP5 trafficking to the APM 10 min after injection of the mAChR agonist cevimeline. Conversely, 60 min after injection, there was a diffuse pattern of AQP5 staining in the cell cytoplasm. The calcium ionophore A-23187 mimicked the effects of cevimeline. Immunoelectron microscopic studies confirmed that cevimeline induced AQP5 trafficking from intracellular structures to APMs in the interlobular duct cells of rat parotid glands. Lipid raft markers flotillin-2 and GM1 colocalized with AQP5 and moved with AQP5 in response to cevimeline. Under control conditions, the majority of AQP5 localized in the Triton X-100-insoluble fraction and floated to the light-density fraction on discontinuous density gradients. After 10-min incubation of parotid tissue slices with cevimeline or A-23187, AQP5 levels decreased in the Triton X-100-insoluble fraction and increased in the Triton X-100-soluble fraction. Thus AQP5 localizes in the intracellular lipid rafts, and M_3 mAChR activation induces AQP5 trafficking to the APM with lipid rafts via intracellular Ca^{2+} signaling and induces AQP5 dissociation from lipid rafts to nonrafts on the APM in the interlobular duct cells of rat parotid glands.

3.672 Loss- and gain-of-function analysis of the lipid raft proteins *reggie/flotillin* in *Drosphilia*: they are posttranslationally regulated, and misexpression interferes with wing and eye development
Hoehne, M., de Couet, H.G., Stuermer, C.A.O. and Fischbach, K-F.
*Mol. Cell. Neurosci., **30**, 326-338 (2005)*

Reggie/Flotillin proteins are upregulated after optic nerve dissection and evolutionary highly conserved components of lipid rafts. Whereas many biochemical and cell culture studies suggest an involvement in the assembly of multiprotein complexes at cell contact sites, not much is known about their biological in vivo functions. We therefore set out to study the expression pattern and the effects of loss- and gain-of-function in the *Drosophila melanogaster* model system. We found that in flies these proteins are mainly expressed in axons at the root of fiber tracts, in places where strong fasciculation is required, e.g. at the neck of the peduncle of the mushroom bodies and in the optic chiasms. Despite their evolutionary conservation which implies fundamental and important functions, a P-element-induced null mutant (KG00210) of *reggie1/flotillin2* (*reggie1/flo2)* in *D. melanogaster* shows no apparent phenotypic defects. This was even more surprising as we show that in this *reggie1/flo2* null mutant the paralogous Reggie2/Flo1 protein is unstable and degraded, while the transcript is still present. The requirement of Reggie1/Flo2 for Reggie2/Flo1 stabilization is confirmed by misexpression experiments. Reggie2/Flo1 can only be misexpressed when Reggie1/Flo2 is provided as well. Conversely, Reggie1/Flo2 immunoreactivity can be detected, when its transgene is misexpressed alone. Using appropriate Gal4 driver lines, misexpression of Reggie1/Flo2 alone or together with Reggie2/Flo1 in the eye imaginal disc results in a specific and severe mislocalization of cell adhesion molecules of the immunoglobulin superfamily (IgCAMs) (while DE-Cadherin is unaffected) and in differentiation defects pointing to impaired signaling. In the wing imaginal disc, global overexpression of Reggie/Flotillin proteins leads to a significant extension of the Wingless signal and severely disrupts normal wing development. Our data support the notion that Reggie/Flotillin proteins are implicated in signaling processes at cellular contact sites.

3.673 Comparative genomic analysis reveals a novel mitochondrial isoform of human rTS protein and unusual phylogenetic distribution of the rTS gene
Liang, P., Nair, J.R., Song, L., McGuire, J.J. and Dolnick, B.J.
*BMC Genomics, **6**, 125 (2005)*

Background

The rTS gene (*ENOSF1*), first identified in *Homo sapiens* as a gene complementary to the thymidylate synthase (*TYMS*) mRNA, is known to encode two protein isoforms, rTSα and rTSβ. The rTSβ isoform appears to be an enzyme responsible for the synthesis of signaling molecules involved in the down-regulation of thymidylate synthase, but the exact cellular functions of rTS genes are largely unknown.
Results
Through comparative genomic sequence analysis, we predicted the existence of a novel protein isoform, rTS, which has a 27 residue longer N-terminus by virtue of utilizing an alternative start codon located upstream of the start codon in rTSβ. We observed that a similar extended N-terminus could be predicted in all rTS genes for which genomic sequences are available and the extended regions are conserved from bacteria to human. Therefore, we reasoned that the protein with the extended N-terminus might represent an ancestral form of the rTS protein. Sequence analysis strongly predicts a mitochondrial signal sequence in the extended N-terminal of human rTSγ, which is absent in rTSβ. We confirmed the existence of rTS in human mitochondria experimentally by demonstrating the presence of both rTSγ and rTSβ proteins in mitochondria isolated by subcellular fractionation. In addition, our comprehensive analysis of rTS orthologous sequences reveals an unusual phylogenetic distribution of this gene, which suggests the occurrence of one or more horizontal gene transfer events.
Conclusion
The presence of two rTS isoforms in mitochondria suggests that the rTS signaling pathway may be active within mitochondria. Our report also presents an example of identifying novel protein isoforms and for improving gene annotation through comparative genomic analysis.

3.674 Brome mosaic virus 1a nucleoside triphosphatase/helicase domain plays crucial roles in recruiting RNA replication templates
Wang, X. et al
J. Virol., ***79(21)****, 13747-13758 (2005)*

Positive-strand RNA virus RNA replication is invariably membrane associated and frequently involves viral proteins with nucleoside triphosphatase (NTPase)/helicase motifs or activities. Brome mosaic virus (BMV) encodes two RNA replication factors: 1a has a C-terminal NTPase/helicase-like domain, and $2a^{pol}$ has a central polymerase domain. 1a accumulates on endoplasmic reticulum membranes, recruits $2a^{pol}$, and induces 50- to 70-nm membrane invaginations (spherules) serving as RNA replication compartments. 1a also recruits BMV replication templates such as genomic RNA3. In the absence of $2a^{pol}$, 1a dramatically stabilizes RNA3 by transferring RNA3 to a membrane-associated, nuclease-resistant state that appears to correspond to the interior of the 1a-induced spherules. Prior results show that the 1a NTPase/helicase-like domain contributes to RNA recruitment. Here, we tested mutations in the conserved helicase motifs of 1a to further define the roles of this domain in RNA template recruitment. All 1a helicase mutations tested showed normal 1a accumulation, localization to perinuclear endoplasmic reticulum membranes, and recruitment of $2a^{pol}$. Most 1a helicase mutants also supported normal spherule formation. Nevertheless, these mutations severely inhibited RNA replication and 1a-induced stabilization of RNA3 in vivo. For such 1a mutants, the membrane-associated RNA3 pool was both reduced and highly susceptible to added nuclease. Thus, 1a recruitment of viral RNA templates to a membrane-associated, nuclease-resistant state requires additional functions beyond forming spherules and recruiting RNA to membranes, and these functions depend on the 1a helicase motifs. The possibility that, similar to some double-stranded RNA viruses, the 1a NTPase/helicase-like domain may be involved in importing viral RNAs into a preformed replication compartment is discussed.

3.675 Nef is physically recruited into the immunological synapse and potentiates T cell activation early after TCR engagemant
Fenard, D. et al
J. Immunol., ***175****, 6050-6057 (2005)*

The HIV-1 protein Nef enhances viral pathogenicity and accelerates disease progression in vivo. Nef potentiates T cell activation by an unknown mechanism, probably by optimizing the intracellular environment for HIV replication. Using a new T cell reporter system, we have found that Nef more than doubles the number of cells expressing the transcription factors NF-κB and NFAT after TCR stimulation. This Nef-induced priming of TCR signaling pathways occurred independently of calcium signaling and involved a very proximal step before protein kinase C activation. Engagement of the TCR by MHC-bound Ag triggers the formation of the immunological synapse by recruiting detergent-resistant membrane microdomains, termed lipid rafts. Approximately 5–10% of the total cellular pool of Nef is localized within lipid rafts. Using confocal and real-time microscopy, we found that Nef in lipid rafts was recruited into the

immunological synapse within minutes after Ab engagement of the TCR/CD3 and CD28 receptors. This recruitment was dependent on the N-terminal domain of Nef encompassing its myristoylation. Nef did not increase the number of cell surface lipid rafts or immunological synapses. Recently, studies have shown a specific interaction of Nef with an active subpopulation of p21-activated kinase-2 found only in the lipid rafts. Thus, the corecruitment of Nef and key cellular partners (e.g., activated p21-activated kinase-2) into the immunological synapse may underlie the increased frequency of cells expressing transcriptionally active forms of NF-κB and NFAT and the resultant changes in T cell activation.

3.676 γ-Secretase is a functional component of phagosomes
Jutras, I. et al
J. Biol. Chem., ***280(43)***, *36310-36317 (2005)*

γ-Secretase is a high molecular mass protein complex that catalyzes the intramembrane cleavage of its protein substrates. Two proteins involved in phagocytosis, CD44 and the low density lipoprotein receptor-related protein, are γ-secretase substrates, suggesting that this complex might regulate some aspects of phagocytosis. Our results indicate that the four components of γ-secretase, *viz.* presenilin, nicastrin, APH-1, and PEN-2, are present and enriched on phagosome membranes from both murine macrophages and *Drosophila* S2 phagocytes. The γ-secretase components form high molecular mass complexes in lipid microdomains of the phagosome membrane with the topology expected for the functional enzyme. In contrast to the majority of the phagosome proteins studied so far, which appear to associate transiently with this organelle, γ-secretase resides on newly formed phagosomes and remains associated throughout their maturation into phagolysosomes. Finally, our results indicate that interferon-γ stimulates γ-secretase-dependent cleavages on phagosomes and that γ-secretase activity may be involved in the phagocytic response of macrophages to inflammatory cytokines.

3.677 The blood-brain barrier transmigrating single domain antibody: mechanism of transport and antigenic epitopes in human brain endothelial cells
Abulrop, A., Sprong, H., Van Bergen en Henegouwen P. and Stanimirovic, D.
J. Neurochem., ***95***, *1201-1214 (2005)*

Antibodies against receptors that undergo transcytosis across the blood–brain barrier (BBB) have been used as vectors to target drugs or therapeutic peptides into the brain. We have recently discovered a novel single domain antibody, FC5, which transmigrates across human cerebral endothelial cells *in vitro* and the BBB *in vivo*. The purpose of this study was to characterize mechanisms of FC5 endocytosis and transcytosis across the BBB and its putative receptor on human brain endothelial cells. The transport of FC5 across human brain endothelial cells was polarized, charge independent and temperature dependent, suggesting a receptor-mediated process. FC5 taken up by human brain endothelial cells co-localized with clathrin but not with caveolin-1 by immunochemistry and was detected in clathrin-enriched subcellular fractions by western blot. The transendothelial migration of FC5 was reduced by inhibitors of clathrin-mediated endocytosis, K^+ depletion and chlorpromazine, but was insensitive to caveolae inhibitors, filipin, nystatin or methyl-β-cyclodextrin. Following internalization, FC5 was targeted to early endosomes, bypassed late endosomes/lysosomes and remained intact after transcytosis. The transcytosis process was inhibited by agents that affect actin cytoskeleton or intracellular signaling through PI3-kinase. Pretreatment of human brain endothelial cells with wheatgerm agglutinin, sialic acid, α(2,3)-neuraminidase or *Maackia amurensis* agglutinin that recognizes α(2,3)-, but not with *Sambucus nigra* agglutinin that recognizes α(2,6) sialylgalactosyl residues, significantly reduced FC5 transcytosis. FC5 failed to recognize brain endothelial cells-derived lipids, suggesting that it binds luminal α(2,3)-sialoglycoprotein receptor which triggers clathrin-mediated endocytosis. This putative receptor may be a new target for developing brain-targeting drug delivery vectors.

3.678 Lipids as modulators of proteolytic activity of BACE. Involvement of cholesterol, glycosphingolipids, and anionic phospholipids in vitro
Kalvodova, L. et al
J. Biol. Chem., ***280(44)***, *36815-36823 (2005)*

The β-secretase, BACE, is a membrane spanning aspartic protease, which cleaves the amyloid precursor protein (APP) in the first step of proteolytic processing leading to the formation of the neurotoxic β-amyloid peptide (Aβ). Previous results have suggested that the regulation of β-secretase and BACE access to APP is lipid dependent, and involves lipid rafts. Using the baculovirus expression system, we have

expressed recombinant human full-length BACE in insect cells and purified milligram amounts to homogeneity. We have studied partitioning of fluorophor-conjugated BACE between the liquid ordered and disordered phases in giant (10–150 μm) unilamellar vesicles, and found ~20% to associate with the raft-like, liquid-ordered phase; the fraction associated with liquid-ordered phase increased upon cross-linking of raft lipids. To examine involvement of individual lipid species in modulating BACE activity, we have reconstituted the purified BACE in large (~100 nm) unilamellar vesicles, and determined its specific activity in vesicles of various lipid compositions. We have identified 3 groups of lipids that stimulate proteolytic activity of BACE: 1) neutral glycosphingolipids (cerebrosides), 2) anionic glycerophospholipids, and 3) sterols (cholesterol).

3.679 Cholesterol-dependent syntaxin-4 and SNAP-23 clustering regulates caveolar fusion with the endothelial plasma
Predescu, S.A., Predescu,, D.N., Shimizu, K., Klein, I.K. and Malik, A.B.
J. Biol. Chem., ***280(44)***, *37130-37138 (2005)*

We determined the organization of target (t) SNARE proteins on the basolateral endothelial plasma membrane (PM) and their role in the mechanism of caveolar fusion. Studies were performed in a cell-free system involving endothelial PM sheets and isolated biotin-labeled caveolae. We monitored the fusion of caveolae with the PM by the detection of biotin-streptavidin complexes using correlative high resolution fluorescence microscopy and gold labeling electron microscopy on ultrathin sections of PM sheets. Imaging of PM sheets demonstrated and biochemical findings showed that the t-SNARE proteins present in endothelial cells (SNAP-23 and syntaxin-4) formed cholesterol-dependent clusters in discrete areas of the PM. Upon fusion of caveolae with the target PM, 50% of the caveolae co-localized with the t-SNARE clusters, indicating that these caveolae were at the peak of the fusion reaction. Fluorescent streptavidin staining of PM sheets correlated with the ultrastructure in the same area. These findings demonstrate that t-SNARE clusters in the endothelial target PM serve as the fusion sites for caveolae during exocytosis.

3.680 Association of human immunodeficiency virus type 1 Gag with membrane does not require highly basic sequences in the nucleocapsid: use of a novel Gag multimerization assay
Ono, A., Waheed, A.A., Joshi, A.a and Freed, E.O.
J. Virol., ***79(22)***, *14131-14140 (2005)*

Human immunodeficiency virus type 1 (HIV-1) particle production, a process driven by the Gag polyprotein precursor, occurs on the plasma membrane in most cell types. The plasma membrane contains cholesterol-enriched microdomains termed lipid rafts, which can be isolated as detergent-resistant membrane (DRM). Previously, we and others demonstrated that HIV-1 Gag is associated with DRM and that disruption of Gag-raft interactions impairs HIV-1 particle production. However, the determinants of Gag-raft association remain undefined. In this study, we developed a novel epitope-based Gag multimerization assay to examine whether Gag assembly is essential for its association with lipid rafts. We observed that membrane-associated, full-length Gag is poorly detected by immunoprecipitation relative to non-membrane-bound Gag. This poor detection is due to assembly-driven masking of Gag epitopes, as denaturation greatly improves immunoprecipitation. Gag mutants lacking the Gag-Gag interaction domain located in the N terminus of the nucleocapsid (NC) were efficiently immunoprecipitated without denaturation, indicating that the epitope masking is caused by higher-order Gag multimerization. We used this assay to examine the relationship between Gag assembly and Gag binding to total cellular membrane and DRM. Importantly, a multimerization-defective NC mutant displayed wild-type levels of membrane binding and DRM association, indicating that NC-mediated Gag multimerization is dispensable for association of Gag with membrane or DRM. We also demonstrate that different properties of sucrose and **iodixanol** membrane flotation gradients may explain some discrepancies regarding Gag-raft interactions. This report offers new insights into the association of HIV-1 Gag with membrane and with lipid rafts.

3.681 A role for Fis1 in both mitochondrial and peroxisomal fission in mammalian cells
Koch, A., Yoon, Y., Bonekamp, N.A., McNiven, M.A. and Schrader, M.
Mol. Biol. Cell, ***16***, *5077-5086 (2005)*

The mammalian dynamin-like protein DLP1/Drp1 has been shown to mediate both mitochondrial and peroxisomal fission. In this study, we have examined whether hFis1, a mammalian homologue of yeast Fis1, which has been shown to participate in mitochondrial fission by an interaction with DLP1/Drp1, is also involved in peroxisomal growth and division. We show that hFis1 localizes to peroxisomes in addition to mitochondria. Through differential tagging and deletion experiments, we demonstrate that the

transmembrane domain and the short C-terminal tail of hFis1 is both necessary and sufficient for its targeting to peroxisomes and mitochondria, whereas the N-terminal region is required for organelle fission. hFis1 promotes peroxisome division upon ectopic expression, whereas silencing of Fis1 by small interfering RNA inhibited fission and caused tubulation of peroxisomes. These findings provide the first evidence for a role of Fis1 in peroxisomal fission and suggest that the fission machinery of mitochondria and peroxisomes shares common components.

3.682 GLUT8 contains a [DE]XXXL[LI] sorting motif and localizes to a late endosomal/lysosomal compartment
Augustin, R., Riley, J. and Moley, K.H.
*Traffic, **6**, 1196-1212 (2005)*

Glucose transporter 8 (GLUT8) contains a cytoplasmic N-terminal dileucine motif and localizes to a thus far unidentified intracellular compartment. Translocation of GLUT8 to the plasma membrane (PM) was found in insulin-treated mouse blastocysts. Using overexpression of GLUT8 in adipocytes and neuronal cells however, insulin treatment or depolarization of the cells did not lead to GLUT8 PM translocation in other studies. In addition, other experiments showing dynamin-dependent endocytosis of GLUT8 suggested that GLUT8 recycles between an endosomal compartment and the PM. To reveal the functional/physiological role of GLUT8, we studied its subcellular localization in 3T3L1, HEK293 and CHO cells. We show that GLUT8 does not co-localize with GLUT4 and does not redistribute to the PM after treatment with insulin, ionophores or okadaic acid in these cell lines. Once endocytosed, GLUT8 does not recycle to the PM. GLUT8 localizes to late endosomes and lysosomes. An interspecies GLUT8 - sequence alignment revealed the presence of a highly conserved late endosomal/lysosomal-targeting motif ([DE]XXXL[LI]). Changing the glutamate to arginine as found in GLUT4 (RRXXXLL) alters GLUT8 endocytosis and retains the transporter at the PM. Furthermore, sorting GLUT8 to late endosomes/lysosomes does not require prior presence of GLUT8 at the PM followed by its endocytosis. In summary, GLUT8 does not reside in a recycling vesicle pool and is distinct from GLUT4. From our data, we postulate a role for GLUT8 in transport of hexoses across intracellular membranes, for example in specific compartments of GLUT8 expression such as the acrosome of mature spermatozoa or secretory granules in neurons. Furthermore, a role for GLUT8 in hexose transport across the lysosomal membrane, a transport mechanism that has long been suggested but unexplained, is discussed.

3.683 The VirE1VirE2 complex of *Agrobacterium tumefaciens* interacts with single-stranded DNA and forms channels
Duckely, M. et al
*Mol. Microbiol., **58(4)**, 1130-1142 (2005)*

The VirE2 protein is crucial for the transfer of single-stranded DNA (ssDNA) from *Agrobacterium tumefaciens* to the nucleus of the plant host cell because of its ssDNA binding activity, assistance in nuclear import and putative ssDNA channel activity. The native form of VirE2 in *Agrobacterium*'s cytoplasm is in complex with its specific chaperone, VirE1. Here, we describe the ability of the VirE1VirE2 complex to both bind ssDNA and form channels. The affinity of the VirE1VirE2 complex for ssDNA is slightly reduced compared with VirE2, but the kinetics of binding to ssDNA are unaffected by the presence of VirE1. Upon binding of VirE1VirE2 to ssDNA, similar helical structures to those reported for the VirE2─ssDNA complex were observed by electron microscopy. The VirE1VirE2 complex can release VirE1 once the VirE2─ssDNA complexes assembled. VirE2 exhibits a low affinity for small unilamellar vesicles composed of bacterial lipids and a high affinity for lipid vesicles containing sterols and sphingolipids, typical components of animal and plant membranes. In contrast, the VirE1VirE2 complex associated similarly with all kind of lipids. Finally, black lipid membrane experiments revealed the ability of the VirE1VirE2 complex to form channels. However, the majority of the channels displayed a conductance that was a third of the conductance of VirE2 channels. Our results demonstrate that the binding of VirE1 to VirE2 does not inhibit VirE2 functions and that the effector─chaperone complex is multifunctional.

3.684 Biochemical characterization of intracellular membranes bearing Trk neurotrophin receptors
Yano, H. and Chao, M.V.
*Neurochem. Res., **30(6/7)**, 767-777 (2005)*

Neurotrophin receptor trafficking plays an important role in directing cellular communication in developing as well as mature neurons. However, little is known about the requirements for intracellular

localization of the neurotrophin receptors in neurons. To isolate the subcellular membrane compartments containing the Trk neurotrophin receptor, we performed biochemical subcellular fractionation experiments using primary cortical neurons and rat PC12 pheochromocytoma cells. By differential centrifugation and density gradient centrifugation, we have isolated Trk-bearing compartments, suggesting distinct membranous localization of Trk receptors. A number of Trk-interacting proteins, such as GIPC and dynein light chain Tctex-1 were found in these fractions. Additionally, membranes enriched in phosphorylated activated forms of Trk receptors were found upon ligand treatment in primary neurons and PC12 cells. Interestingly, density gradient centrifugation experiments showed that Trk receptors from PC12 cells are present in heavy membrane fractions, while Trk from primary neurons are fractionated in lighter membrane fractions. These results suggest that the intracellular membrane localization of Trk can differ according to cell type. Taken together, these biochemical approaches allowed separation of distinct Trk-bearing membrane pools, which may be involved in different functions of neurotrophin receptor signaling and trafficking.

3.685 Cytotoxicity of an anti-cancer lysophospholipid through selective modification of lipid raft composition

Zaremberg, V., Gajate, C., Cacharro, L.M., Mollinedo, F. and McMaster, C.R.
J. Biol. Chem., ***280(45)***, *38047-38058 (2005)*

Edelfosine is a prototypical member of the alkylphosphocholine class of antitumor drugs. *Saccharomyces cerevisiae* was used to screen for genes that modulate edelfosine cytotoxicity and identified sterol and sphingolipid pathways as relevant regulators. Edelfosine addition to yeast resulted in the selective partitioning of the essential plasma membrane protein Pma1p out of lipid rafts. Microscopic analysis revealed that Pma1p moved from the plasma membrane to intracellular punctate regions and finally localized to the vacuole. Consistent with altered sterol and sphingolipid synthesis resulting in increased edelfosine sensitivity, mislocalization of Pma1p was preceded by the movement of sterols out of the plasma membrane. Cells with enfeebled endocytosis and vacuolar protease activities prevented edelfosine-mediated (i) mobilization of sterols, (ii) loss of Pma1p from lipid rafts, and (iii) cell death. The activities of proteins and signaling processes are meaningfully altered by changes in lipid raft biophysical properties. This study points to a novel mode of action for an anti-cancer drug through modification of plasma membrane lipid composition resulting in the displacement of an essential protein from lipid rafts.

3.686 Thermally induced changes in lipid composition of raft and non-raft regions of hepatocyte plasma membranes of rainbow trout

Zehmer, J.K. and Hazel, J.R.
J. Exp. Biol., ***208***, *4283-4290 (2005)*

In poikilotherms, increases in plasma membrane (PM) cholesterol and an increase in the degree of lipid acyl chain saturation commonly accompany an increase in growth temperature. This has typically been interpreted in terms of membrane fluidity/order homeostasis, but these changes would also be expected to stabilize the structure of PM rafts against thermal perturbation. Rafts are microdomains that organize the molecules of many signaling cascades and are formed as a result of interactions between lipids with saturated acyl chains and cholesterol. No study to date has examined the thermally induced compositional changes of raft and non-raft regions of the PM separately. In this study we have measured the phospholipid class composition and fatty acid composition of raft-enriched (raft) and raft-depleted PM (RDPM) of hepatocytes from trout *Oncorhynchus mykiss* acclimated to 5°C and 20°C. In the raft, warm acclimation was associated with a reduction in the proportion of phosphatidylcholine from 56% to 30% while phosphatidylserine and phosphatidylinositol each increased from 8% to approximately 20% of the total phospholipid. Additionally, there were significantly fewer unsaturated fatty acids in the raft lipids from warm-acclimated (61%) than from the cold-acclimated trout (68%). In contrast, there were no significant changes in phospholipid class or acyl chain unsaturation in the RDPM. These data suggest that changes in raft lipid composition, rather than the PM as a whole, are particularly important during thermal acclimation.

3.687 A primate virus generates transformed human cells by fusion

Duelli, D.M., Hearn, S., Myers, M.P. and Lazebnik, Y.
J. Cell Biol., ***171(3)***, *493-503 (2005)*

Amodel that explains both the origin and sporadic nature of cancer argues that cancer cells are a chance result of events that cause genomic and epigenetic variability. The prevailing view is that these events are

mutations that affect chromosome segregation or stability. However, genomic and epigenetic variability is also triggered by cell fusion, which is often caused by viruses. Yet, cells fused by viruses are considered harmless because they die. We provide evidence that a primate virus uses both viral and exosomal proteins involved in cell fusion to produce transformed proliferating human cells. Although normal cells indeed fail to proliferate after fusion, expression of an oncogene or a mutated tumor suppressor p53 in just one of the fusion partners is sufficient to produce heterogeneous progeny. We also show that this virus can produce viable oncogenically transformed cells by fusing cells that are otherwise destined to die. Therefore, we argue that viruses can contribute to carcinogenesis by fusing cells.

3.688 Plasma membrane and lysosomal localization of CB1 cannabinoid receptor are dependent on lipid rafts and regulated by anandamide in human breast cancer cells
Sarnataro, D. et al
FEBS Lett., ***579***, *6343-6349 (2005)*

In this report we show, by confocal analysis of indirect immunofluorescence, that the type-1 cannabinoid receptor (CB1R), which belongs to the family of G-protein-coupled receptors, is expressed on the plasma membrane in human breast cancer MDA-MB-231 cells. However, a substantial proportion of the receptor is present in lysosomes. We found that CB1R is associated with cholesterol- and sphyngolipid-enriched membrane domains (rafts). Cholesterol depletion by methyl-β-cyclodextrin (MCD) treatment strongly reduces the flotation of the protein on the raft-fractions (DRM) of sucrose density gradients suggesting that CB1 raft-association is cholesterol dependent. Interestingly binding of the agonist, anandamide (AEA) also impairs DRM-association of the receptor suggesting that the membrane distribution of the receptor is dependent on rafts and is possibly regulated by the agonist binding. Indeed MCD completely blocked the clustering of CB1R at the plasma membrane. On the contrary the lysosomal localization of CB1R was impaired by this treatment only after AEA binding.

3.689 Effect of cholesterol depletion on mitogenesis and survival: the role of caveolar and noncaveolar domains in insulin-like growth factor-mediated cellular function
Matthews, L.C., Taggart, M.J. and Westwood, M.
Endocrinol., ***146(12)***, *5463-5473 (2005)*

The type 1 IGF receptor (IGF-IR) is thought to localize to a subset of lipid rafts, known as caveolae, but the impact on IGF signaling remains controversial. We investigated this potential regulatory mechanism by assessing IGF function in caveolae-positive (3T3L1 and NWTb3) and -negative (HepG2) cells. Coimmunoprecipitation studies demonstrated that IGF-IR and insulin receptor substrate 1 associated with caveolin, a caveolar marker, in 3T3L1 and NWTb3 cells. Subcellular fractionation showed that methyl-cyclodextrin, which disrupts lipid rafts by sequestration of cholesterol, disrupted the colocalization of caveolin and the IGF-IR at the plasma membrane. Methyl-cyclodextrin did not alter IGF-I-induced 3T3L1 or NWTb3 proliferation but significantly impaired the ability of IGF-I to protect these cells from apoptosis. Immunoblotting revealed that methyl-cyclodextrin had no effect on IGF-I-induced activation of the IGF-IR or insulin receptor substrate 1 but increased and decreased the phosphorylation of MAPK and protein kinase B, respectively. In caveolae-negative HepG2 cells, the effect of methyl-cyclodextrin on IGF signaling and cellular function was similar to that observed in caveolae-positive 3T3L1 and NWTb3 cells. Furthermore, transfecting caveolin into HepG2 cells to give morphologically identifiable caveolae made no difference to IGF action, despite a demonstrable interaction between caveolin and the IGF-IR. This suggests that although IGF-IR localizes to caveolin-rich subcellular fractions and coimmunoprecipitates with caveolin, caveolae may not be obligatory for IGF signaling.

3.690 The ubiquitously expressed Csk adaptor protein Cbp is dispensable for embryogenesis and T-cell development and function
Dobenecker, M-W., Schmedt, C., Okada, M. And Tarakhovsky, A.
Mol. Cell. Biol., ***25(23)***, *10533-10542 (2005)*

Regulation of Src family kinase (SFK) activity is indispensable for a functional immune system and embryogenesis. The activity of SFKs is inhibited by the presence of the carboxy-terminal Src kinase (Csk) at the cell membrane. Thus, recruitment of cytosolic Csk to the membrane-associated SFKs is crucial for its regulatory function. Previous studies utilizing in vitro and transgenic models suggested that the Csk-binding protein (Cbp), also known as phosphoprotein associated with glycosphingolipid microdomains (PAG), is the membrane adaptor for Csk. However, loss-of-function genetic evidence to support this notion was lacking. Herein, we demonstrate that the targeted disruption of the *cbp* gene in mice has no effect on

embryogenesis, thymic development, or T-cell functions in vivo. Moreover, recruitment of Csk to the specialized membrane compartment of "lipid rafts" is not impaired by Cbp deficiency. Our results indicate that Cbp is dispensable for the recruitment of Csk to the membrane and that another Csk adaptor, yet to be discovered, compensates for the loss of Cbp.

3.691 Different effects of intracochlear sensory and neuronal injury stimulation on expression of synaptic N-methyl-D-aspartate receptors in the auditory cortex of rats in vivo
Wang, Z., Ruan, Q. and Wang, D.
*Acta Oto-Laryngologica, **125**, 1145-1151 (2005)*

Conclusions. The expression of synaptic N-methyl-D-aspartate (NMDA) receptors in the auditory cortex is dynamic and is bidirectionally regulated by auditory activity. Furthermore, the time course of changes in the level of NR2A protein differs after sensory and neuronal injury stimulation, which modulate different changes in synaptic plasticity. Objective. To examine the effects of different types of auditory activity on the expression of synaptic NMDA receptors (NMDARs) in the auditory cortex of rats. Material and methods. We prepared synaptosomes from the auditory cortices of postnatal Day 28 ototoxic-deafened Sprague–Dawley rats and postnatal Day 28 Sprague–Dawley rats subjected to noise trauma that were given various treatments and compared them to the synaptosomes of 1–6-week-old normal Sprague–Dawley rats. The expression of different NMDAR subunits in the synaptosomes was investigated by means of Western blotting. Results. Changes in NR1 and NR2B proteins were not significant during different types of auditory activity. The level of NR2A protein increased remarkably during postnatal development and as a result of electrical intracochlear stimulation, auditory deprivation and noise trauma. Seventy-two h after a 2-h period of sensory electrical intracochlear stimulation, the expression of NR2A protein returned to the level caused by auditory deprivation. Seventy-two h after a 3-h period of noise trauma, elevation of the level of NR2A protein was unchanged. We also confirmed that elevation of the level of synaptic NR2A protein was sensitive to protein synthesis inhibitor and NMDAR antagonist. However, transcription inhibitor had no effect on NR2A protein expression.

3.692 Defective insulin receptor activation and altered lipid rafts in Niemann-Pick type C diseases hepatocytes
Vainio, S. et al
*Biochem. J., **391**, 465-472 (2005)*

Niemann–Pick type C (NPC) disease is a neuro-visceral cholesterol storage disorder caused by mutations in the *NPC-1* or *NPC-2* gene. In the present paper, we studied IR (insulin receptor) activation and the plasma-membrane lipid assembly in primary hepatocytes from control and NPC1–/– mice. We have previously reported that, in hepatocytes, IR activation is dependent on cholesterol–sphingolipid rafts [Vainio, Heino, Mansson, Fredman, Kuismanen, Vaarala and Ikonen (2002) EMBO Rep. **3**, 95–100]. We found that, in NPC hepatocytes, IR levels were up-regulated and the receptor activation was compromised. Defective IR activation was reproduced in isolated NPC plasma-membrane preparations, which displayed an increased cholesterol content and saturation of major phospholipids. The NPC plasma membranes were less fluid than control membranes as indicated by increased DPH (1,6-diphenyl-1,3,5-hexatriene) fluorescence anisotropy values. Both in NPC hepatocytes and plasma-membrane fractions, the association of IR with low-density DRMs (detergent-resistant membranes) was increased. Moreover, the detergent resistance of both cholesterol and phosphatidylcholine were increased in NPC membranes. Finally, cholesterol removal inhibited IR activation in control membranes but restored IR activation in NPC membranes. Taken together, the results reveal a lipid imbalance in the NPC hepatocyte, which increases lipid ordering in the plasma membrane, alters the properties of lipid rafts and interferes with the function of a raft-associated plasma-membrane receptor. Such a mechanism may participate in the pathogenesis of NPC disease and contribute to insulin resistance in other disorders of lipid metabolism.

3.693 Malonyl-CoA decarboxylase is present in the cytosolic, mitochondrial and peroxisomal compartments of rat hepatocytes
Joly, E. et al

FEBS Lett., ***579(29)***, *6581-6586 (2005)*

A role for cytosolic malonyl-CoA decarboxylase (MCD) as a regulator of fatty acid oxidation has been postulated. However, there is no direct evidence that MCD is present in the cytosol. To address this issue, we performed cell fractionation and electron microscopic colloidal gold studies of rat liver to determine the location and activity of MCD. By both methods, substantial amounts of MCD protein and activity were found in the cytosol, mitochondria and peroxisomes, the latter with the highest specific activity. MCD species with different electrophoretic mobility were observed in the three fractions. The data demonstrate that active MCD is present in the cytosol, mitochondria and peroxisomes of rat liver, consistent with the view that MCD participates in the regulation of cytosolic malonyl-CoA levels and of hepatic fatty acid oxidation.

3.694 **Defects in structural integrity of ergosterol and the Cdc50p-Drs2p putative phospholipid translocase cause accumulation of endocytic membranes, onto which actin parches are assembled in yeast**
Kishimoto, T., Yamamoto, T. and Tanaka, K.
Mol. Biol. Cell, ***16***, *5592-5609 (2005)*

Specific changes in membrane lipid composition are implicated in actin cytoskeletal organization, vesicle formation, and control of cell polarity. Cdc50p, a membrane protein in the endosomal/*trans*-Golgi network compartments, is a noncatalytic subunit of Drs2p, which is implicated in translocation of phospholipids across lipid bilayers. We found that the *cdc50*Δ mutation is synthetically lethal with mutations affecting the late steps of ergosterol synthesis (*erg2* to *erg6*). Defects in cell polarity and actin organization were observed in the *cdc50*Δ *erg3*Δ mutant. In particular, actin patches, which are normally found at cortical sites, were assembled intracellularly along with their assembly factors, including Las17p, Abp1p, and Sla2p. The exocytic SNARE Snc1p, which is recycled by an endocytic route, was also intracellularly accumulated, and inhibition of endocytic internalization suppressed the cytoplasmic accumulation of both Las17p and Snc1p. Simultaneous loss of both phospholipid asymmetry and sterol structural integrity could lead to accumulation of endocytic intermediates capable of initiating assembly of actin patches in the cytoplasm.

3.695 **A genome-wide visual screen reveals a role for sphingolipids and ergosterol in cell surface delivery in yeast**
Proszynski, T.J. et al
PNAS, ***102(50)***, *17981-17986 (2005)*

Recently synthesized proteins are sorted at the trans-Golgi network into specialized routes for exocytosis. Surprisingly little is known about the underlying molecular machinery. Here, we present a visual screen to search for proteins involved in cargo sorting and vesicle formation. We expressed a GFP-tagged plasma membrane protein in the yeast deletion library and identified mutants with altered marker localization. This screen revealed a requirement of several enzymes regulating the synthesis of sphingolipids and ergosterol in the correct and efficient delivery of the marker protein to the cell surface. Additionally, we identified mutants regulating the actin cytoskeleton (Rvs161p and Vrp1p), known membrane traffic regulators (Kes1p and Chs5p), and several unknown genes. This visual screening method can now be used for different cargo proteins to search in a genome-wide fashion for machinery involved in post-Golgi sorting.

3.696 **Expression and activity of NOX5 in the circulating malignant B cells of hairy cell leukemia**
Kamiguti, A.S. et al
J. Immunol., ***175***, *8424-8430 (2005)*

Hairy cells (HCs) are mature malignant B cells that contain a number of constitutively active signaling molecules including GTP-bound Rac1, protein kinase C, and Src family kinases. Because Rac1 is a component of the reactive oxidant species (ROS)-generating NADPH oxidase system, we investigated the role of this GTPase in ROS production in HCs. In this study, we show that ROS production in HCs involves a flavin-containing oxidase dependent on Ca^{2+}, but not on GTP-Rac1 or protein kinase C. This suggests the involvement of the nonphagocytic NADPH oxidase NOX5, an enzyme found in lymphoid tissues, but not in circulating lymphocytes. By using RT-PCR and Southern and Western blotting and by measuring superoxide anion production in membrane fractions in the absence of cytosolic components, we

demonstrate for the first time that HCs (but not circulating normal B cells or some other lymphoid cell types) express NOX5. We also demonstrate that inhibition of NADPH oxidase in HCs results in a selective increase in the activity of Src homology region 2 domain-containing phosphatase 1 (SHP-1). Furthermore, SHP-1 in HCs coimmunoprecipitates with tyrosine phosphorylated CD22 and localizes in the same cellular compartment as NOX5. This allows the inactivation of SHP-1 by NOX5-generated ROS and contributes to the maintenance of the constitutive activation of HCs.

3.697 Solute traffic across mammalian peroxisomal membrane – single-channel conductance monitoring reveals pore-forming activities in peroxisomes
Antonenkov, V.D., Rokka, A., Sormunen, R.T., Benz, R. And Hiltunen, J.K.
Cell. Mol. Life Sci., ***62***, *2886-2895 (2005)*

Mouse liver peroxisomes were isolated by centrifugation in a self-generated Percoll gradient followed by an Optiprep density gradient centrifugation. Peroxisomes contributed 90–96% of the total protein content in the fraction, as confirmed by marker enzyme assays, protein pattern in SDS-PAGE, immunoblotting, and electron microscopy. Solubilized peroxisomal membrane proteins were reconstituted into a planar lipid bilayer. A single-channel conductance monitoring of the reconstituted lipid bilayer revealed the presence of two pore-forming components with a conductance in 1 M KCl of 1.3 nS and 2.5 nS. Control experiments with fractions enriched in mitochondria, lysosomes, and fragments of endoplasmic reticulum showed that the peroxisomal channel-forming activities were not due to admixture of isolated peroxisomes with other cellular organelles. The peroxisomal channels were well preserved in membrane preparations but became unstable after solubilization from the membranes by detergent.

3.698 The compartmentalization of prolactin signaling in the mouse mammary gland
Bolander Jr., F.F.
Mol. Cell. Endocrinol., ***245(1-2)***, *105-110 (2005)*

In mammary epithelial cells, prolactin (PRL) activates at least two signaling pathways: Jak/Stat and nitric oxide (NO). The former induces differentiation as measured by α-lactalbumin accumulation, while experiments with sodium nitroprusside (SNP) show that NO inhibits differentiation. In order to resolve this apparent contradiction, the kinetics, inducibility, and cellular localization of NO production and sensitivity in mammary cells were examined. First, mammary cells remained responsive to PRL throughout the incubation with respect to NO production. Second, although desensitization occurred with continuous PRL exposure, recovery began as quickly as 30 min after PRL withdrawal. Since PRL is secreted in pulses in vivo, complete desensitization was not a likely explanation for the cells' escape from NO inhibition. Finally, the cellular site of transduction was examined using the caveolar disrupting agent, methyl-β-cyclodextrin (MBCD). MBCD inhibited the accumulation of PRL-induced NO but not α-lactalbumin. This finding was confirmed by membrane fractionation studies where the PRL-induced NO production occurred primarily in caveolae and PRL-stimulated tyrosine phosphorylation of Stat5, which transcribes the α-lactalbumin gene, occurred predominantly in noncaveolar membranes. Finally, endogenous elevations of NO by arginine did not inhibit differentiation. As such, the inhibition seen with SNP appeared to be an artifact of the ubiquitous generation of NO from SNP. Physiologically, PRL induces NO only in caveolae and this restricted distribution does not interfere with differentiation.

3.699 Oestrogen-mediated tyrosine phosphorylation of caveolin-1 and its effect on the oestrogen receptor localization: an in vivo study
Kiss, A.L. et al
Mol. Cell. Endocrinol., ***245(1-2)***, *128-137 (2005)*

Recently, it has been shown that 17β estradiol (E2) induces a rapid and transient activation of the Src ERK phosphorylation cascade: a clear indication that the α oestrogen receptor (ERα) is able to associate with the plasma membrane. Increasing evidence suggests that caveolae, which are caveolin-1 containing, highly hydrophobic membrane domains, play an important role in E2 induced signal transduction. Caveolae can accumulate signalling molecules preferentially; thus, they may have a regulatory role in signalling processes. Results from previous experiments have shown that E2 treatment decreased the number of surface connected caveolae significantly in uterine smooth muscle cells and also downregulated the expression of caveolin-1. In addition to providing further evidence that ERα interacts with caveolin/caveolae in uterine smooth muscle cells, this study also shows that the interaction between caveolin-1 and ERα is actually facilitated by E2. One of the signal transduction components found to accumulate in caveolae is Src kinase in an amount that increases simultaneously with increases in the

amount of ERα. Upon E2 treatment, Src kinase is tyrosine phosphorylated, which, in turn, stimulates Src kinase to phosphorylate caveolin-1. Phosphorylation of caveolin-1 can drive caveolae to pinch off from the plasma membrane, thereby decreasing the amount of plasma membrane-associated caveolin-1. This loss of caveolin/caveolae activates the signal cascade that triggers cell proliferation.

3.700 Sorghum Genome Sequencing by Methylation Filtration
Bedell, J.A. et al
*PloS Biol., **3(1)**, 103-115 (2005)*

Sorghum bicolor is a close relative of maize and is a staple crop in Africa and much of the developing world because of its superior tolerance of arid growth conditions. We have generated sequence from the hypomethylated portion of the sorghum genome by applying methylation filtration (MF) technology. The evidence suggests that 96% of the genes have been sequence tagged, with an average coverage of 65% across their length. Remarkably, this level of gene discovery was accomplished after generating a raw coverage of less than 300 megabases of the 735-megabase genome. MF preferentially captures exons and introns, promoters, microRNAs, and simple sequence repeats, and minimizes interspersed repeats, thus providing a robust view of the functional parts of the genome. The sorghum MF sequence set is beneficial to research on sorghum and is also a powerful resource for comparative genomics among the grasses and across the entire plant kingdom. Thousands of hypothetical gene predictions in rice and *Arabidopsis* are supported by the sorghum dataset, and genomic similarities highlight evolutionarily conserved regions that will lead to a better understanding of rice and *Arabidopsis*.

3.701 T cell receptor-induced lipid raft recruitment of the IκB kinase complex is necessary and sufficient for NF-κB activation occurring in the cytosol
Sebald, A., Mattioli, I. and Schmitz, M.L.
*Eur. J. Immunol., **35(1)**, 318-325 (2005)*

TCR-induced NF-κB activation is necessary for the innate immune response and involves induced lipid raft recruitment of the IκB kinase (IKK) complex. In this study, we systematically investigated lipid raft recruitment of members of the NF-κB activation pathway in human T cells. All upstream components leading to IKK activation were found constitutively or inducibly in lipid rafts, while the NF-κB/IκB complex and phosphorylated forms of IKKα/β, IκBα and p65 are exclusively found in the cytosolic fraction. Disruption of raft organization precluded NF-κB activation induced by T cell costimulation, but IL-1-triggered NF-κB activation remained unaffected. Targeting of the IKK complex to lipid rafts caused constitutive IKK activation and NF-κB DNA binding, which was further triggered upon T cell costimulation. Various experimental approaches revealed that costimulation-induced IKKα/β activation loop phosphorylation is independent from IKKβ-mediated transautophosphorylation, but rather involves phosphorylation by the IKK-interacting protein NIK and its upstream activator COT.

3.702 *Leishmania donovani* lipophosphoglycan disrupts phagosome microdomains in J774 macrophages
Dermine. J-F., Goyette, G., Houde, M., Turco, S.J. and Desjardins, M.
*Cell. Microbiol., **7(9)**, 1263-1270 (2005)*

Clearance of pathogens by phagocytosis and their killing in phagolysosomes is a key aspect of our innate ability to fight infectious agents. Leishmania parasites have evolved ways to survive and replicate in macrophages by inhibiting phagosome maturation and avoiding the harsh environment of phagolysosomes. We describe here that during this process Leishmania donovani uses a novel strategy involving its surface lipophosphoglycan (LPG), a virulence factor impeding many host functions, to prevent the formation or disrupt lipid microdomains on the phagosome membrane. LPG acts locally on the membrane and requires its repetitive carbohydrate moieties to alter the organization of microdomains. Targeting and disruption of functional foci, where proteins involved in key aspects of phagolysosome biogenesis assemble, is likely to confer a survival advantage to the parasite.

3.703 Intragranular Vesiculotubular Compartments are Involved in Piecemeal Degranulation by Activated Human Eosinophils
Melo, R.C.N., Perez, S.A.C., Spencer, L.A., Dvorak, A.M. and Weller, P.F.
*Traffic, **6(10)**, 866-879 (2005)*

Eosinophils, leukocytes involved in allergic, inflammatory and immunoregulatory responses, have a distinct capacity to rapidly secrete preformed granule-stored proteins through piecemeal degranulation (PMD), a secretion process based on vesicular transport of proteins from within granules for extracellular release. Eosinophil-specific granules contain cytokines and cationic proteins, such as major basic protein (MBP). We evaluated structural mechanisms responsible for mobilizing proteins from within eosinophil granules. Human eosinophils stimulated for 30–60 min with eotaxin, regulated on activation, normal, T-cell expressed and secreted (RANTES) or platelet activating factor exhibited ultrastructural features of PMD (e.g. losses of granule contents) and extensive vesiculotubular networks within emptying granules. Brefeldin A inhibited granule emptying and collapsed intragranular vesiculotubular networks. By immunonanogold ultrastructural labelings, CD63, a tetraspanin membrane protein, was localized within granules and on vesicles outside of granules, and mobilization of MBP into vesicles within and extending from granules was demonstrated. Electron tomography with three dimension reconstructions revealed granule internal membranes to constitute an elaborate tubular network able to sequester and relocate granule products upon stimulation. We provide new insights into PMD and identify eosinophil specific granules as organelles whose internal tubulovesicular networks are important for the capacity of eosinophils to secrete, by vesicular transport, their content of preformed and granule-stored cytokines and cationic proteins.

3.704 Peroxisomal proteomics, a new tool for risk assessment of peroxisome proliferating pollutants in the marine environment

Mi, J., Orbea, A., Syme, N., Ahmed, M., Cajaraville, M.P. and Cristobal, S.
*Proteomics, **5(15)**, 3954-2965 (2005)*

In an attempt to improve the detection of peroxisome proliferation as a biomarker in environmental pollution assessment, we have applied a novel approach based on peroxisomal proteomics. Peroxisomal proteins from digestive glands of mussels *Mytilus galloprovincialis* were analyzed using 2-DE and MS. We have generated a reference 2-DE map from samples obtained in a well-studied reference area and compared this with peroxisomal proteomes from other sequenced genomes. In addition, by comparing 2-DE maps from control samples with samples obtained in a polluted area, we have characterized the peroxisome proliferation expression pattern associated with exposure to a polluted environment. Over 100 spots were reproducibly resolved per 2-DE map; 55 differentially expressed spots were quantitatively detected and analyzed, and 14 of these showed an increase in protein expression of more than fourfold. Epoxide hydrolase, peroxisomal antioxidant enzyme, and sarcosine oxidase (SOX) have been identified by ESI MS/MS, and acyl-CoA oxidase, multifunctional protein, and Cu,Zn-superoxide dismutase were immunolocalized by Western blotting. Our results indicate that a peroxisomal protein pattern associated to marine pollutant exposure can be generated, and this approach may have a greater potential as biomarker than traditional, single-protein markers.

3.705 Altered regulation of EGF receptor signaling following a partial hepatectomy

Skarpen, E., Oksvold, M.P., Grøsvik, H., Widnes, C. and Huitfeldt, H.S.
*J. Cell. Physiol., **202(3)**, 707-716 (2005)*

We have studied epidermal growth factor receptor (EGFR) phosphorylation and localization in the pre-replicative phase of liver regeneration induced by a 70% partial hepatectomy (PH), and how a PH affects EGFR activation and trafficking. When Western blotting was performed on livers after PH with antibodies raised against activated forms of EGFR autophosphorylation sites, no marked increase in EGFR tyrosine phosphorylation was observed. However, events associated with attenuation of EGFR signals were observed. Two hours after PH, we found increased EGFR ubiquitination and internalization, followed by receptor downregulation. Furthermore, EGFR phosphorylation following an injection of EGF was reduced after PH. This reduction correlated with an increased activation of PKC and a distinct augmentation in the phosphorylation of the PKC-regulated T654-site of EGFR. When primary cultured hepatocytes were treated with tetradecanoylphorbol acetate (TPA) to induce T654-phosphorylation of EGFR, we found colocalization of a fraction of EGFR with EEA1, downregulation of EGF-mediated EGFR autophosphorylation, altered ligand-induced intracellular sorting of EGFR, and increased mitogenic signaling through the EGFR-Ras-Raf-ERK pathway. Further, we found that both TPA and a PH enhanced EGF-induced proliferation of hepatocytes. In conclusion, our results suggest that hepatocyte priming involves modulation of EGFR that enhances its ability to mediate growth factor responses without an increase in its receptor tyrosine kinase-activity. This may be a pre-replicative competence event that increases growth factor effects during G1 progression.

3.706 Characterization of myosin-II binding to Golgi stacks in vitro
Fath, K.R.
Cell Motil. Cytoskeleton, ***60(4)****, 222-235 (2005)*

In addition to important roles near the actin-rich cell cortex, ample evidence indicates that multiple myosins are also involved in membrane movements in the endomembrane system. Nonmuscle myosin-II has been shown to have roles in anterograde and retrograde trafficking at the Golgi. Myosin-II is present on Golgi stacks isolated from intestinal epithelial cells and has been localized to the Golgi in several polarized and unpolarized cell lines. An understanding of roles of myosin-II in Golgi physiology will be facilitated by understanding the molecular arrangement of myosin-II at the Golgi. Salt-washing removes endogenous myosin-II from isolated Golgi and purified brush border myosin-II can bind in vitro. Brush border myosin-II binds to a tightly bound Golgi peripheral membrane protein with a $K_{1/2}$ of 75 nM and binding is saturated at 0.7 pmol myosin/μg Golgi. Binding studies using papain cleavage fragments of brush border myosin-II show that the 120-kDa rod domain, but not the head domain, of myosin heavy chain can bind directly to Golgi stacks. The 120-kDa domain does not bind to Golgi membranes when phosphorylated in vitro with casein kinase-II. These results suggest that phosphorylation in the rod domain may regulate the binding and/or release of myosin-II from the Golgi. These data support a model in which myosin-II is tethered to the Golgi membrane by its tail and actin filaments by its head. Thus, translocation along actin filaments may extend Golgi membrane tubules and/or vesicles away from the Golgi complex.

3.707 The unconventional myosin-VIIa associates with lysosomes
Soni, L.E., Warren, C.M., Bucci, C., Orten, D.J. and Hasson, T.
Cell Motil. Cytoskeleton, ***62(1)****, 13-26 (2005)*

Mutations in the myosin-VIIa (*MYO7a*) gene cause human Usher disease, characterized by hearing impairment and progressive retinal degeneration. In the retina, myosin-VIIa is highly expressed in the retinal pigment epithelium, where it plays a role in the positioning of melanosomes and other digestion organelles. Using a human cultured retinal pigmented epithelia cell line, ARPE-19, as a model system, we have found that a population of myosin-VIIa is associated with cathepsin D- and Rab7-positive lysosomes. Association of myosin-VIIa with lysosomes was Rab7 independent, as dominant negative and dominant active versions of Rab7 did not disrupt myosin-VIIa recruitment to lysosomes. Association of myosin-VIIa with lysosomes was also independent of the actin and microtubule cytoskeleton. Myosin-VIIa copurified with lysosomes on density gradients, and fractionation and extraction experiments suggested that it was tightly associated with the lysosome surface. These studies suggest that myosin-VIIa is a lysosome motor.

3.708 Release of the type I secreted α-haemolysin via outer membrane vesicles from *Escherichia coli*
Balsalobre, C. et al
Mol. Microbiol., ***59(1)****, 99-112 (2006)*

The α-haemolysin is an important virulence factor commonly expressed by extraintestinal pathogenic *Escherichia coli*. The secretion of the α-haemolysin is mediated by the type I secretion system and the toxin reaches the extracellular space without the formation of periplasmic intermediates presumably in a soluble form. Surprisingly, we found that a fraction of this type I secreted protein is located within outer membrane vesicles (OMVs) that are released by the bacteria. The α-haemolysin appeared very tightly associated with the OMVs as judged by dissociation assays and proteinase susceptibility tests. The α-haemolysin in OMVs was cytotoxically active and caused lysis of red blood cells. The OMVs containing the α-haemolysin were distinct from the OMVs not containing α-haemolysin, showing a lower density. Furthermore, they differed in protein composition and one component of the type I secretion system, the TolC protein, was found in the lower density vesicles. Studies of natural isolates of *E. coli* demonstrated that the localization of α-haemolysin in OMVs is a common feature among haemolytic strains. We propose an alternative pathway for the transport of the type I secreted α-haemolysin from the bacteria to the host cells during bacterial infections.

3.709 Nox2 and Rac1 regulate H_2O_2-dependent recruitment of TRAFg to endosomal interleukin-1 receptor complexes
Li, Q. et al
Mol. Cell. Biol., ***26(1)****, 140-154 (2006)*

Reactive oxygen species (ROS) generated by NADPH oxidases (Nox) have been implicated in the regulation of signal transduction. However, the cellular mechanisms that link Nox activation with plasma membrane receptor signaling remain poorly defined. We have found that Nox2-derived ROS influence the formation of an active interleukin-1 (IL-1) receptor complex in the endosomal compartment by directing the H_2O_2-dependent binding of TRAF6 to the IL-1R1/MyD88 complex. Clearance of both superoxide and H_2O_2 from within the endosomal compartment significantly abrogated IL-1ß-dependent IKK and NF-κB activation. MyD88-dependent endocytosis of IL-1R1 following IL-1ß binding was required for the redox-dependent formation of an active endosomal receptor complex competent for IKK and NF-κB activation. Small interfering RNAs to either MyD88 or Rac1 inhibited IL-1ß induction of endosomal superoxide and NF-κB activation. However, MyD88 and Rac1 appear to be recruited independently to IL-1R1 following ligand stimulation. In this context, MyD88 binding was required for inducing endocytosis of IL-1R1 following ligand binding, while Rac1 facilitated the recruitment of Nox2 into the endosomal compartment and subsequent redox-dependent recruitment of TRAF6 to the MyD88/IL-1R1 complex. The identification of Nox-active endosomes helps explain how subcellular compartmentalization of redox signals can be used to direct receptor activation from the plasma membrane.

3.710 Lipid raft clustering and redox signaling platform formation in coronary arterial endothelial cells
Zhung, A.Y., Yi, F., Zhang, G., Gulbins, E. and Li, P-L.
*Hypertension, **47**, 74-80 (2006)*

Recent studies have indicated that lipid rafts (LRs) in the cell membrane are clustered in response to different stimuli to form signaling platforms for transmembrane transduction. It remains unknown whether this LR clustering participates in redox signaling in endothelial cells. The present study tested a hypothesis that clustering of LRs on the membrane of coronary endothelial cells produces aggregation and activation of reduced nicotinamide-adenine dinucleotide phosphate (NADPH) oxidase, thereby forming a redox signaling platform. By confocal microscopic analysis of agonist-stimulated rafts patch formation, we found that several death receptor ligands or apoptotic factors, including tumor necrosis factor [alpha], Fas ligand, or endostatin, stimulated the clustering and trafficking of individual LRs on the plasma membrane of coronary endothelial cells. Interestingly, double labeling of a membrane-bound NADPH oxidase subunit, gp91phox, and LRs showed that gp91phox colocalized within the LR patches when endothelial cells were stimulated by Fas ligand. In isolated LR fractions from Fas-stimulated endothelial cells, gp91phox, p47phox (a crucial cytosolic regulatory subunit of NADPH oxidase), and Rac GTPase were markedly increased and blocked by nystatin, a compound that disrupts LRs. These clustered LRs contained high NADPH oxidase activity, which increased in response to Fas stimulation. Functionally, Fas ligand-induced inhibition of endothelium-dependent vasorelaxation was reduced if LRs were disrupted or NADPH oxidase was inhibited. These results suggest that LR clustering occurs in coronary endothelial cells. The formation of redox signaling platforms on the cell membrane mediates transmembrane signaling of death receptors, resulting in endothelial dysfunction.

3.711 Significance of sterol structural specificity
Vainio, S. et al
*J. Biol. Chem., **281(1)**, 348-355 (2006)*

Desmosterol is an immediate precursor of cholesterol in the Bloch pathway of sterol synthesis and an abundant membrane lipid in specific cell types. The significance of the difference between the two sterols, an additional double bond at position C24 in the tail of desmosterol, is not known. Here, we provide evidence that the biophysical and functional characteristics of the two sterols differ and that this is because the double bond at C24 significantly weakens the sterol ordering potential. In model membranes, desmosterol was significantly weaker than cholesterol in promoting the formation or stability of ordered domains, and in mammalian cell membranes, desmosterol associated less avidly than cholesterol with detergent-resistant membranes. Atomic scale molecular dynamics simulations showed that the double bond gives rise to additional stress in the tail, creating a rigid structure between C24 and C27 and favoring tilting of desmosterol distinct from cholesterol. Functional effects of desmosterol in cell membranes were assessed upon acutely exchanging ~70% of cholesterol to desmosterol. This led to impaired raft-dependent signaling via the insulin receptor, whereas non-raft-dependent protein secretion was not affected. We suggest that the choice of cholesterol synthesis route may provide a physiological mechanism to modulate raft-dependent functions in cells.

3.712 Detection of a raft-located estrogen receptor-like protein distinct from ERα
Heberden, C. et al

*Int. J. Biochem. Cell Biol., **38**, 376-391 (2006)*

17β-Estradiol (17β-E2) elicits at the cell membrane rapid actions that remain insensitive to the inhibitory effect of ICI 182,780, a pure estrogen antagonist, and therefore cannot be attributed to the classic nuclear receptors. We addressed the question of the identity of the protein involved in these rapid actions. We first examined the responses of several cell lines for intracellular calcium mobilization, an effect not inhibited by ICI 182,780, tamoxifen and raloxifen. We then demonstrated the presence of binding sites in the membranes, by incubating them with antibodies directed against different domains of ERα, and by flow cytometry analysis. The membrane proteins were eluted by affinity chromatography using E2 conjugated to bovine serum albumin as a ligand. Western blots of the elution fractions using an antibody directed against the ligand binding site of ERα showed the existence of a protein of ~50 kDa. The protein was concentrated in the lipid rafts, together with another heavier form of ~66 kDa. The 50 kDa protein was immunoprecipitable, and co-immunoprecipitation experiments showed that it was associated with the $G\beta_{1-4}$ protein, but not with caveolin-1. The protein was expressed in ERα-null cells, like HO-23 and Cos-7 cells. Therefore, in the lipid rafts, there exists a protein, similar to, but molecularly distinct from ERα..

3.713 Identification of a switch in neurotrophin signaling by selective tyrosine phosphorylation
Arevalo, J., Pereira, D.B., Yano, H., Teng, K.K. and Chao, M.V.
*J. Biol. Chem., **281(2)**, 1001-1007 (2006)*

Neurotrophins, such as nerve growth factor and brain-derived neurotrophic factor, activate Trk receptor tyrosine kinases through receptor dimerization at the cell surface followed by autophosphorylation and recruitment of intracellular signaling molecules. The intracellular pathways used by neurotrophins share many common protein substrates that are used by other receptor tyrosine kinases (RTK), such as Shc, Grb2, FRS2, and phospholipase C-γ. Here we describe a novel RTK mechanism that involves a 220-kilodalton membrane tetraspanning protein, ARMS/Kidins220, which is rapidly tyrosine phosphorylated in primary neurons after neurotrophin treatment. ARMS/Kidins220 undergoes multiple tyrosine phosphorylation events and also serine phosphorylation by protein kinase D. We have identified a single tyrosine (Tyr^{1096}) phosphorylation event in ARMS/Kidins220 that plays a critical role in neurotrophin signaling. A reassembled complex of ARMS/Kidins220 and CrkL, an upstream component of the C3G-Rap1-MAP kinase cascade, is SH3-dependent. However, Tyr^{1096} phosphorylation enables ARMS/Kidins220 to recruit CrkL through its SH2 domain, thereby freeing the CrkL SH3 domain to engage C3G for MAP kinase activation in a neurotrophin dependent manner. Accordingly, mutation of Tyr^{1096} abolished CrkL interaction and sustained MAPK kinase activity, a response that is not normally observed in other RTKs. Therefore, Trk receptor signaling involves an inducible switch mechanism through an unconventional substrate that distinguishes neurotrophin action from other growth factor receptors.

3.714 From assembly to virus particle budding: pertince of the detergent resisitant membranes
Gosselin-Grenet, A-S., Mottet-Osman, G. and Roux, L.
*Virology, **344(2)**, 296-303 (2006)*

Detergent resistant membranes (DRMs) are the site of assembly for a variety of viruses. Here, we make use of Sendai virus mutant proteins that are not packaged into virus particles to determine the involvement of this assembly for the virus particle production. We found that, in the context of an infection, (1) all the Sendai virus proteins associated in part with DRMs, (2) mutant HN and M proteins not packaged into virus particles were similarly part of this association, (3) after M protein suppression resulting in a significant reduction of virus production, the floatation profile of the other viral proteins was not altered and finally (4) cellular cholesterol depletion did not decrease the virus particle production, although it somehow reduced their virus infectivity. These results led us to conclude that the assembly complex found in DRM fractions does not constitute a direct precursor of virus particle budding.

3.715 Roles of ZO-1, accludin, and actin in axidant-induced barrier disruption
Musch, M.W., Walsh-Reitz, M.W. and Chang, E.B.
*Am. J. Physiol., **290**, G222-G231 (2006)*

Oxidants such as monochloramine (NH_2Cl) decrease epithelial barrier function by disrupting perijunctional actin and possibly affecting the distribution of tight junctional proteins. These effects can, in theory, disturb cell polarization and affect critical membrane proteins by compromising molecular fence function of the tight junctions. To examine these possibilities, we investigated the actions of NH_2Cl on the distribution, function, and integrity of barrier-associated membrane, cytoskeletal, and adaptor proteins in human colonic

Caco-2 epithelial monolayers. NH_2Cl causes a time-dependent decrease in both detergent-insoluble and -soluble zonula occludens (ZO)-1 abundance, more rapidly in the former. Decreases in occludin levels in the detergent-insoluble fraction were observed soon after the fall of ZO-1 levels. The actin depolymerizer cytochalasin D resulted in a decreased transepithelial resistance (TER) more quickly than NH_2Cl but caused a more modest and slower reduction in ZO-1 levels and in occludin redistribution. No changes in the cellular distribution of claudin-1, claudin-5, or ZO-2 were observed after NH_2Cl. However, in subsequent studies, the immunofluorescent cellular staining pattern of all these proteins was altered by NH_2Cl. The actin-stabilizing agent phalloidin did not prevent NH_2Cl-induced decreases in TER or increases of apical to basolateral flux of the paracellular permeability marker mannitol. However, it partially blocked changes in ZO-1 and occludin distribution. Tight junctional fence function was also compromised by NH_2Cl, observed as a redistribution of the α-subunit of basolateral Na^+-K^+-ATPase to the apical membrane, an effect not found with the apical membrane protein Na^+/H^+ exchanger isoform 3. In conclusion, oxidants not only disrupt perijunctional actin but also cause redistribution of tight junctional proteins, resulting in compromised intestinal epithelial barrier and fence function. These effects are likely to contribute to the development of malabsorption and dysfunction associated with mucosal inflammation of the digestive tract.

3.716 Focal adhesion kinase is critical for entry of Kaposi's sarcoma-associated herpesvirus into target cells

Krisham, H.H., Sharma-Walia, N., Streblow, D.N., Naranatt, P.P. and Chandran, B.
J. Virol., ***80(3)***, *1167-1180 (2006)*

Kaposi's sarcoma-associated herpesvirus/human herpesvirus 8 (KSHV/HHV-8) interacts with cell surface α3ß1 integrin early during in vitro infection of human endothelial cells and fibroblasts and activates the focal adhesion kinase (FAK) that is immediately downstream in the outside-in signaling pathway by integrins, leading to the activation of several downstream signaling molecules. In this study, using real-time DNA and reverse transcription-PCR assays to measure total internalized viral DNA, viral DNA associated with infected nuclei, and viral gene expression, we examined the stage of infection at which FAK plays the most significant role. Early during KSHV infection, FAK was phosphorylated in FAK-positive Du17 mouse embryonic fibroblasts. The absence of FAK in Du3 ($FAK^{-/-}$) cells resulted in about 70% reduction in the internalization of viral DNA, suggesting that FAK plays a role in KSHV entry. Expression of FAK in Du3 ($FAK^{-/-}$) cells via an adenovirus vector augmented the internalization of viral DNA. Expression of the FAK dominant-negative mutant FAK-related nonkinase (FRNK) in Du17 cells significantly reduced the entry of virus. Virus entry in Du3 cells, albeit in reduced quantity, delivery of viral DNA to the infected cell nuclei, and expression of KSHV genes suggested that in the absence of FAK, another molecule(s) may be partially compensating for FAK function. Infection of Du3 cells induced the phosphorylation of the FAK-related proline-rich tyrosine kinase (Pyk2) molecule, which has been shown to complement some of the functions of FAK. Expression of an autophosphorylation site mutant of Pyk2 in which Y402 is mutated to F (F402 Pyk2) reduced viral entry in Du3 cells, suggesting that Pyk2 facilitates viral entry moderately in the absence of FAK. These results suggest a critical role for KSHV infection-induced FAK in the internalization of viral DNA into target cells.

3.717 Quality control of a mutant plasma membrane ATPase: ubiquitylation prevents cell-surface stability

Liu, Y. and Chang, A.
J. Cell Sci., ***119***, *360-369 (2006)*

The plasma membrane ATPase, Pma1, has remarkable longevity at the cell surface. In contrast to the wild-type protein, the temperature-sensitive mutant Pma1-10 is misfolded and undergoes rapid removal from the cell surface for vacuolar degradation. At the restrictive temperature, Pma1-10 becomes ubiquitylated before or upon arrival at the plasma membrane. Internalization from the plasma membrane and vacuolar degradation of Pma1-10 is dependent on the ubiquitin-interacting motif (UIM) of the epsin Ent1, suggesting recognition of ubiquitylated substrate by the endocytic machinery. Surprisingly, ubiquitylation of Pma1-10 is reversed when its internalization is blocked in an *end3* mutant. Under these conditions, Pma1-10 acquires association with detergent-insoluble, glycolipid-enriched complexes (DIGs) which has been suggested to promote stability of wild-type Pma1. Ubiquitylation does not cause DIG exclusion because a Pma1-Ub fusion protein is not significantly excluded from DIGs. We suggest that ubiquitylation of Pma1-10 represents a component of a quality control mechanism that targets the misfolded protein for removal from the plasma membrane. Rapid internalization of Pma1-10 caused by its ubiquitylation may preempt establishment of stabilizing interactions.

3.718 Protein kinase Cε interacts with cytochrome c oxidase subunit IV and enhances cytochrome c oxidase activity in neonatal cardiac myocyte preconditioning
Ogbi, M. and Johnson, J.A.
Biochem. J., ***393(1)***, *191-199 (2006)*

We have previously identified a phorbol ester-induced PKCε (protein kinase Cε) interaction with the (~18 kDa) COIV [CO (cytochrome *c* oxidase) subunit IV] in NCMs (neonatal cardiac myocytes). Since PKCε has been implicated as a key mediator of cardiac PC (preconditioning), we examined whether hypoxic PC could induce PKCε–COIV interactions. Similar to our recent study with phorbol esters [Ogbi, Chew, Pohl, Stuchlik, Ogbi and Johnson (2004) Biochem. J. **382**, 923–932], we observed a time-dependent increase in the *in vitro* phosphorylation of an approx. 18 kDa protein in particulate cell fractions isolated from NCMs subjected to 1–60 min of hypoxia. Introduction of a PKCε-selective translocation inhibitor into cells attenuated this *in vitro* phosphorylation. Furthermore, when mitochondria isolated from NCMs exposed to 30 min of hypoxia were subjected to immunoprecipitation analyses using PKCε-selective antisera, we observed an 11.1-fold increase in PKCε–COIV co-precipitation. In addition, we observed up to 4-fold increases in CO activity after brief NCM hypoxia exposures that were also attenuated by introducing a PKCε-selective translocation inhibitor into the cells. Finally, in Western-blot analyses, we observed a >2-fold PC-induced protection of COIV levels after 9 h index hypoxia. Our studies suggest that a PKCε–COIV interaction and an enhancement of CO activity occur in NCM hypoxic PC. We therefore propose novel mechanisms of PKCε-mediated PC involving enhanced energetics, decreased mitochondrial reactive oxygen species production and the preservation of COIV levels.

3.719 CD16b associates with high-density, detergent-resistant membranes in human neutrophils
Fernandes, M.J.G. et al
Biochem. J., ***393(2)***, *351-359 (2006)*

CD16b is unique in that it is the only Fc receptor linked to the plasma membrane by a GPI (glycosylphosphatidylinositol) anchor. GPI-anchored proteins often preferentially localize to DRMs (detergent-resistant membranes) that are rich in sphingolipids and cholesterol and play an important role in signal transduction. Even though the responses to CD16b engagement have been intensively investigated, the importance of DRM integrity for CD16b signalling has not been characterized in human neutrophils. We provide direct evidence that CD16b constitutively partitions with both low- and high-density DRMs. Moreover, upon CD16b engagement, a significant increase in the amount of the receptor is observed in high-density DRMs. Similarly to CD16b, CD11b also resides in low- and high-density DRMs. In contrast with CD16b, the partitioning of CD11b in DRMs does not change in response to CD16b engagement. We also provide evidence for the implication of Syk in CD16b signalling and its partitioning to DRMs in resting and activated PMNs (polymorphonuclear neutrophils). Additionally, DRM-disrupting agents, such as nystatin and methyl-β-cyclodextrin, alter cellular responses to CD16b receptor ligation. Notably, a significant increase in the mobilization of intracellular Ca^{2+} and in tyrosine phosphorylation of intracellular substrates after CD16b engagement is observed. Altogether, the results of this study provide evidence that high-density DRMs play a role in CD16b signalling in human neutrophils.

3.720 Receptor palmitoylation and ubiquitination regulate anthrax toxin endocytosis
Abrami, L., Leppla, S.H., Gisou van der Gaat, F.
J. Cell Biol., ***171(2)***, *309-320 (2006)*

The anthrax toxin is composed of three independent polypeptide chains. Successful intoxication only occurs when heptamerization of the receptor-binding polypeptide, the protective antigen (PA), allows binding of the two enzymatic subunits before endocytosis. We show that this tailored behavior is caused by two counteracting posttranslational modifications in the cytoplasmic tail of PA receptors. The receptor is palmitoylated, and this unexpectedly prevents its association with lipid rafts and, thus, its premature ubiquitination. This second modification, which is mediated by the E3 ubiquitin ligase Cbl, only occurs in rafts and is required for rapid endocytosis of the receptor. As a consequence, cells expressing palmitoylation-defective mutant receptors are less sensitive to anthrax toxin because of a lower number of surface receptors as well as premature internalization of PA without a requirement for heptamerization.

3.721 Deactivation of phosporylated and nonphosphorylated rhodopsin by arrestin splice variants
Burns, M.E. et al
J. Neurosci., ***26(3)***, *1036-1044 (2006)*

Arrestins constitute a family of small cytoplasmic proteins that mediate deactivation of G-protein-coupled receptors (GPCRs) and are known to be essential for cascade inactivation and receptor desensitization. Alternative splicing produces an array of arrestin gene products that have widely different specificities for their cognate receptors *in vitro*, but the differential functions of these splice variants *in vivo* are essentially unknown. Bovine rod photoreceptors express two splice variants of visual arrestin (p44 and p48) that display different affinities for the GPCR rhodopsin. To determine the functions of these splice variants in intact cells, we expressed a transgene encoding either a truncated form of murine arrestin ($mArr^{1–369}$, or m44) or the long (p48) isoform in mouse rods lacking endogenous arrestin (Arr–/–). Morphological analysis showed that expression of either variant attenuated the light-induced degeneration that is thought to result from excessive cascade activity in Arr–/–rods. Suction electrode recordings from individual rods indicated that the expression of either m44 or p48 splice variants could restore normal kinetics to Arr–/– dim flash responses, indicating that both isoforms can bind to and quench phosphorylated rhodopsin rapidly. To our surprise, only the full-length variant was able to alter the kinetics of responses in rods lacking both arrestin and rhodopsin kinase, indicating that p48 can also quench the activity of nonphosphorylated rhodopsin.

3.722 LMP1 signaling and activation of NF-κB LMP1 transgenic mice
Thornburg, N.J. et al
*Oncogene, **25**, 288-297 (2006)*

Transgenic mice expressing Epstein–Barr virus (EBV) latent membrane protein 1 (LMP1) under the control of an immunoglobulin heavy-chain promoter and enhancer develop lymphoma at a threefold higher incidence than LMP1-negative mice. *In vitro*, LMP1 activates numerous signaling pathways including p38, c-Jun N terminal kinase (JNK), phosphatidylinositol 3 kinase (PI3K)/Akt, and NF-κB through interactions with tumor necrosis receptor-associated factors (TRAFs). These pathways are frequently activated in EBV-associated malignancies, although their activation cannot be definitively linked to LMP1 expression *in vivo*.

In this study, interactions between LMP1 and TRAFs and the activation of PI3K/Akt, JNK, p38, and NF-κB were examined in LMP1 transgenic mice. LMP1 co-immunoprecipitated with TRAFs 1, 2, and 3. Akt, JNK, and p38 were activated in LMP1-positive and -negative splenocytes as well as LMP1-positive and -negative lymphomas. Multiple forms of NF-κB were activated in healthy splenocytes from LMP1 transgenic mice, in contrast to healthy splenocytes from LMP1-negative mice. However, in both LMP1-positive and -negative lymphomas, only the oncogenic NF-κB c-Rel, was specifically activated. Similarly to EBV-associated malignancies, p53 protein was detected at high levels in the transgenic lymphomas, although mutations were not detected in the p53 gene. These data indicate that NF-κB is activated in LMP1-positive healthy splenocytes; however, NF-κB c-Rel is specifically activated in both the transgenic lymphomas and in the rare lymphomas that develop in negative mice. The LMP1-mediated activation of NF-κB may contribute to the specific activation of c-Rel and lead to the increased development of lymphoma in the LMP1 transgenic mice.

3.723 Intracytoplasmic maturation of the human immunodeficiency virus type I reverse transcription complexes determines their capacity to integrate into chromatin
Iodanskiy, S., Berro, R., Altieri, M., Kashanchi, F. And Bukrinsky, M.
*Retrovirology, **3(4)**, 1-12 (2006)*

Background
The early events of the HIV-1 life cycle include entry of the viral core into target cell, assembly of the reverse transcription complex (RTCs) performing reverse transcription, its transformation into integration-competent complexes called pre-integration complexes (PICs), trafficking of complexes into the nucleus, and finally integration of the viral DNA into chromatin. Molecular details and temporal organization of these processes remain among the least investigated and most controversial problems in the biology of HIV.
Results
To quantitatively evaluate maturation and nuclear translocation of the HIV-1 RTCs, nucleoprotein complexes isolated from the nucleus (nRTC) and cytoplasm (cRTC) of HeLa cells infected with MLV Env-pseudotyped HIV-1 were analyzed by real-time PCR. While most complexes completed reverse transcription in the cytoplasm, some got into the nucleus before completing DNA synthesis. The HIV-specific RNA complexes could get into the nucleus when reverse transcription was blocked by reverse

transcriptase inhibitor, although nuclear import of RNA complexes was less efficient than of DNA-containing RTCs. Analysis of the RTC nuclear import in synchronized cells infected in the G2/M phase of the cell cycle showed enrichment in the nuclei of RTCs containing incomplete HIV-1 DNA compared to non-synchronized cells, where RTCs with complete reverse transcripts prevailed. Immunoprecipitation assays identified viral proteins IN, Vpr, MA, and cellular Ini1 and PML associated with both cRTCs and nRTCs, whereas CA was detected only in cRTCs and RT was diminished in nRTCs. Cytoplasmic maturation of the complexes was associated with increased immunoreactivity with anti-Vpr and anti-IN antibodies, and decreased reactivity with antibodies to RT. Both cRTCs and nRTCs carried out endogenous reverse transcription reaction *in vitro*. In contrast to cRTCs, *in vitro* completion of reverse transcription in nRTCs did not increase their integration into chromatin.
Conclusion
These results suggest that RTC maturation occurs predominantly in the cytoplasm. Immature RTCs containing RT and incomplete DNA can translocate into the nucleus during mitosis and complete reverse transcription, but are defective for integration.

3.724 Glycosylphosphatidylinositol-anchored proteins are required for the transport pg detergent-resistant microdomain-associated membrane proteins Tat2p and Fur4p
Okamoto, M., Yoko-o, T., Umemura, M., Nakayama, K-i. and Jigami, Y.
J. Biol. Chem., ***281(7)***, *4013-4023 (2006)*

In eukaryotic cells many cell surface proteins are attached to the membrane via the glycosylphosphatidylinositol (GPI) moiety. In yeast, GPI also plays important roles in the production of mannoprotein in the cell wall. We previously isolated *gwt1* mutants and found that *GWT1* is required for inositol acylation in the GPI biosynthetic pathway. In this study we isolated a new *gwt1* mutant allele, *gwt1-10*, that shows not only high temperature sensitivity but also low temperature sensitivity. The *gwt1-10* cells show impaired acyltransferase activity and attachment of GPI to proteins even at the permissive temperature. We identified *TAT2*, which encodes a high affinity tryptophan permease, as a multicopy suppressor of cold sensitivity in *gwt1-10* cells. The *gwt1-10* cells were also defective in the import of tryptophan, and a lack of tryptophan caused low temperature sensitivity. Microscopic observation revealed that Tat2p is not transported to the plasma membrane but is retained in the endoplasmic reticulum in *gwt1-10* cells grown under tryptophan-poor conditions. We found that Tat2p was not associated with detergent-resistant membranes (DRMs), which are required for the recruitment of Tat2p to the plasma membrane. A similar result was obtained for Fur4p, a uracil permease localized in the DRMs of the plasma membrane. These results indicate that GPI-anchored proteins are required for the recruitment of membrane proteins Tat2p and Fur4p to the plasma membrane via DRMs, suggesting that some membrane proteins are redistributed in the cell in response to environmental and nutritional conditions due to an association with DRMs that is dependent on GPI-anchored proteins.

3.725 Involvement of lipid rafts and caveolae in cardiac ion channel function
Maguy, A., Hebert, T.E. and Nattel, S.
Cardiovasc. Res., ***69(4)***, *798-807 (2006)*

A variety of lipid microdomains, including caveolae, have been shown to play an important role in both protein targetting and in controlling protein–protein interactions. There is increasing evidence for significant ion channel localization in lipid rafts. Cardiac channel subunits known to localize in lipid rafts include Kv1.4, Kv1.5, Kv2.1, Kv4, Kir2, Kir3, K_{ATP}, Nav and Cav subunits. This article reviews what is known about the occurrence and functional significance of cardiac ion channel/lipid raft interactions. Much remains to be learned about this area of potentially enormous importance to cardiac function in health and disease.

3.726 Notch, epidermal growth factor receptor, and β1-integrin pathways are coordinated in neural stem cells
Campos, L., Decker, L., Taylor, V. and Skarnes, W.
J. Biol. Chem., ***281(8)***, *5300-5309 (2006)*

Notch1 and β1-integrins are cell surface receptors involved in the recognition of the niche that surrounds stem cells through cell-cell and cell-extracellular matrix interactions, respectively. Notch1 is also involved in the control of cell fate choices in the developing central nervous system (Lewis, J. (1998) *Semin. Cell Dev. Biol.* 9, 583-589). Here we report that Notch and β1-integrins are co-expressed and that these proteins cooperate with the epidermal growth factor receptor in neural progenitors. We describe data that suggests

that β1-integrins may affect Notch signaling through 1) physical interaction (sequestration) of the Notch intracellular domain fragment by the cytoplasmic tail of the β1-integrin and 2) affecting trafficking of the Notch intracellular domain via caveolin-mediated mechanisms. Our findings suggest that caveolin 1-containing lipid rafts play a role in the coordination and coupling of β1-integrin, Notch1, and tyrosine kinase receptor signaling pathways. We speculate that this will require the presence of the adequate β1-activating extracellular matrix or growth factors in restricted regions of the central nervous system and namely in neurogenic niches.

3.727 **Association of brefeldin A-inhibited guanine nucleotide-exchange protein 2 (BIG2) with recycling endosomes during transferring uptake**
Shen, X. et al
*PNAS, **103(8)**, 2635-2640 (2006)*

ADP-ribosylation factors (ARFs) are critical in vesicular trafficking. Brefeldin A-inhibited guanine nucleotide-exchange protein (BIG)1 and BIG2 activate ARFs by accelerating replacement of bound GDP with GTP. Additional and differing functions of these ≈200-kDa proteins are now being recognized, as are their independent intracellular movements. Here, we describe the localization in COS7 cells by immunofluorescence microscopy of BIG2, but not BIG1, with structures that have characteristics of recycling endosomes during transferrin (Tfn) uptake and Tfn receptor (TfnR) recycling. Cell content of BIG2 and Rab11, but not TfnR, BIG1, Rab4, or Exo70, was increased after 60 min of Tfn uptake. BIG2, but not BIG1, appeared in density-gradient fractions containing TfnR, Rab11, and Exo70 after 60 min of Tfn uptake. Treatment of cells with BIG2 small interfering RNA (siRNA), but not BIG1 or control siRNAs, decreased BIG2 protein >90% without affecting BIG1, ARF, or actin content, whereas TfnR was significantly increased as was its accumulation in perinuclear recycling endosomes. Tfn release appeared unaffected by BIG1 siRNA but was significantly slowed from cells treated with BIG2 siRNA alone or plus BIG1 siRNA. We suggest that BIG2 has an important role in Tfn uptake and TfnR recycling, perhaps through its demonstrated interaction with Exo70 and the exocyst complex.

3.728 **The HIV lipodome: a raft with an unusual composition**
Brügger, B. et al
*PNAS, **103(8)**, 2641-2646 (2006)*

The lipids of enveloped viruses play critical roles in viral morphogenesis and infectivity. They are derived from the host membranes from which virus budding occurs, but the precise lipid composition has not been determined for any virus. Employing mass spectrometry, this study provides a quantitative analysis of the lipid constituents of HIV and a comprehensive comparison with its host membranes. Both a substantial enrichment of the unusual sphingolipid dihydrosphingomyelin and a loss of viral infectivity upon inhibition of sphingolipid biosynthesis in host cells are reported, establishing a critical role for this lipid class in the HIV replication cycle. Intriguingly, the overall lipid composition of native HIV membranes resembles detergent-resistant membrane microdomains and is strikingly different from that of host cell membranes. With this composition, the HIV lipidome provides strong evidence for the existence of lipid rafts in living cells.

3.729 **Vesicle-associated membrane protein 7 is expressed in intestinal ER**
Siddiqi, S., Mathan, J., Siddiqi, S., Gorelick, F.S. and Mansbach, C.M.
*J. Cell Sci., **119**, 943-950 (2006)*

Intestinal dietary triacylglycerol absorption is a multi-step process. Triacylglycerol exit from the endoplasmic reticulum (ER) is the rate-limiting step in the progress of the lipid from its apical absorption to its basolateral membrane export. Triacylglycerol is transported from the ER to the cis Golgi in a specialized vesicle, the pre-chylomicron transport vesicle (PCTV). The vesicle-associated membrane protein 7 (VAMP7) was found to be more concentrated on PCTVs compared with ER membranes. VAMP7 has been previously identified associated with post-Golgi sites in eukaryotes. To examine the potential role of VAMP7 in PCTV trafficking, antibodies were generated that identified a 25 kDa band consistent with VAMP7 but did not crossreact with VAMP1,2. VAMP7 was concentrated on intestinal ER by immunofluorescence microscopy. Immunoelectron microscopy showed that the ER proteins Sar1 and rBet1 were present on PCTVs and colocalized with VAMP7. **Iodixanol** gradient centrifugation showed VAMP7 to be isodense with ER and endosomes. Although VAMP7 localized to intestinal ER, it was not present in

the ER of liver and kidney. Anti-VAMP7 antibodies reduced the transfer of triacylglycerol, but not newly synthesized proteins, from the ER to the Golgi by 85%. We conclude that VAMP7 is enriched in intestinal ER and that it plays a functional role in the delivery of triacylglycerol from the ER to the Golgi.

3.730 Conditioned medium from enterohemorrhagic *Escherichia coli*-infected T84 cells inhibits signal transducer and activator of transcription 1 activation by gamma interferon
Jandu, N. Et al
*Infect. Immun., **74(3)**, 1809-1818 (2006)*

Gamma interferon (IFN-γ) is a cytokine important to host defense which can signal through signal transducer and activator of transcription 1 (Stat1). Enterohemorrhagic *Escherichia coli* (EHEC) modulates host cell signal transduction to establish infection, and EHEC serotypes O113:H21 and O157:H7 both inhibit IFN-γ-induced Stat1 tyrosine phosphorylation in vitro. The aim of this study was to delineate both bacterial and host cell factors involved in the inhibition of Stat1 tyrosine phosphorylation. Human T84 colonic epithelial cells were challenged with direct infection, viable EHEC separated from T84 cells by a filter, sodium orthovanadate, isolated flagellin, bacterial culture supernatants, and conditioned medium treated with proteinase K, trypsin, or heat inactivation. Epithelial cells were then stimulated with IFN-γ and protein extracts were analyzed by immunoblotting. The data showed that IFN-γ-inducible Stat1 tyrosine phosphorylation was inhibited when EHEC adhered to T84 cells, but not by bacterial culture supernatants or bacteria separated from the epithelial monolayer. Conditioned medium from T84 cells infected with EHEC O157:H7 suppressed Stat1 activation, and this was not reversed by treatment with proteinases or heat inactivation. Use of pharmacological inhibitors showed that time-dependent bacterial, but not epithelial, protein synthesis was involved. Stat1 inhibition was also independent of bacterial flagellin, host proteasome activity, and protein tyrosine phosphatases. Infection led to altered IFN-γ receptor domain 1 subcellular distribution and decreased expression in cholesterol-enriched membrane microdomains. Thus, suppression of host cell IFN-γ signaling by production of a contact-dependent, soluble EHEC factor may represent a novel mechanism for this pathogen to evade the host immune system.

3.731 The association of Shiga-like toxin with detergent-resistant membranes is modulated by glucosylceramide and is an essential requirement in the endoplasmic reticulum for a cytotoxic effect
Smith, D.C. et al
*Mol. Biol. Cell, **17**, 1375-1387 (2006)*

Receptor-mediated internalization to the endoplasmic reticulum (ER) and subsequent retro-translocation to the cytosol are essential sequential processes required for the productive intoxication of susceptible mammalian cells by Shiga-like toxin-1 (SLTx). Recently, it has been proposed that the observed association of certain ER-directed toxins and viruses with detergent-resistant membranes (DRM) may provide a general mechanism for their retrograde transport to endoplasmic reticulum (ER). Here, we show that DRM recruitment of SLTx bound to its globotriosylceramide (Gb_3) receptor is mediated by the availability of other glycosphingolipids. Reduction in glucosylceramide (GlcCer) levels led to complete protection against SLTx and a reduced cell surface association of bound toxin with DRM. This reduction still allowed efficient binding and transport of the toxin to the ER. However, toxin sequestration within DRM of the ER was abolished under reduced GlcCer conditions, suggesting that an association of toxin with lipid microdomains or rafts in the ER (where these are defined by detergent insolubility) is essential for a later step leading to or involving retro-translocation of SLTx across the ER membrane. In support of this, we show that a number of ER residents, proteins intimately involved in the process of ER dislocation of misfolded proteins, are present in DRM.

3.732 Cytokine receptor-mediated trafficking of preformed IL-4 in eosinophils identifies an innate immune mechanism of cytokine secretion
Spencer, L.A. et al
*PNAS, **103(9)**, 3333-3338 (2006)*

Although leukocytes of the innate immune system, including eosinophils, contain within their granules preformed stores of cytokines available for selective and rapid release, little is known about the mechanisms governing the mobilization and secretion of these cytokines. Here we show that a cytokine receptor, the IL-4 receptor α chain, mediates eotaxin-stimulated mobilization of preformed IL-4 from eosinophil granules into secretory vesicles. Eosinophils contain substantial intracellular quantities of several granule- and vesicle-associated cytokine receptors, including IL-4, IL-6, and IL-13 receptors as

well as CCR3. Both IL-4 and IL-4 receptor α chain colocalized in eosinophil granules; and after eotaxin-stimulation, IL-4 receptor α chain, bearing bound IL-4, was mobilized into secretory vesicles. These findings indicate that intracellular cytokine receptors within secretory vesicles transport their cognate cytokines requisite for the secretion of cytokines preformed in innate immune leukocytes.

3.733 Glial cell line-derived neurotrophic factor-dependent recruitment of ret into lipid rafts enhances signaling by partitioning ret from proteasome-dependent degradation
Pierchala, B.A., Milbrandt, J. and Johnson Jr., E.M.
J. Neurosci., ***26(10)****, 2777-2787 (2006)*

The receptor tyrosine kinase (RTK) Ret is activated by the formation of a complex consisting of ligands such as glial cell line-derived neurotrophic factor (GDNF) and glycerophosphatidylinositol-anchored coreceptors termed GFRαs. During activation, Ret translocates into lipid rafts, which is critical for functional responses to GDNF. We found that Ret was rapidly ubiquitinated and degraded in sympathetic neurons when activated with GDNF, but, unlike other RTKs that are trafficked to lysosomes for degradation, Ret was degraded predominantly by the proteasome. After GDNF stimulation, the majority of ubiquitinated Ret was located outside of lipid rafts and Ret was lost predominantly from nonraft membrane domains. Consistent with the predominance of Ret degradation outside of rafts, disruption of lipid rafts in neurons did not alter either the GDNF-dependent ubiquitination or degradation of Ret. GDNF-mediated survival of sympathetic neurons was inhibited by lipid raft depletion, and this inhibitory effect of raft disruption on GDNF-mediated survival was reversed if Ret degradation was blocked via proteasome inhibition. Therefore, lipid rafts sequester Ret away from the degradation machinery located in nonraft membrane domains, such as Cbl family E3 ligases, thereby sustaining Ret signaling.

3.734 Sorting of Pmel17 to melanosomes through the plasma membrane by AP1 and AP2: evidence for the polarized nature of melanocytes
Valencia, J.C. et al
J. Cell Sci., ***119****, 1080-1091 (2006)*

Adaptor proteins (AP) play important roles in the sorting of proteins from the trans-Golgi network, but how they function in the sorting of various melanosome-specific proteins such as Pmel17, an essential structural component of melanosomes, in melanocytes is unknown. We characterized the processing and trafficking of Pmel17 via adaptor protein complexes within melanocytic cells. Proteomics analysis detected Pmel17, AP1 and AP2, but not AP3 or AP4 in early melanosomes. Real-time PCR, immunolabeling and tissue in-situ hybridization confirmed the coexpression of AP1 isoforms μ1A and μ1B (expressed only in polarized cells) in melanocytes and keratinocytes, but expression of μ1B is missing in some melanoma cell lines. Transfection with AP1 isoforms (μ1A or μ1B) showed two distinct distribution patterns that involved Pmel17, and only μ1B was able to restore the sorting of Pmel17 to the plasma membrane in cells lacking μ1B expression. Finally, we established that expression of μ1B is regulated physiologically in melanocytes by UV radiation or DKK1. These results show that Pmel17 is sorted to melanosomes by various intracellular routes, directly or indirectly through the plasma membrane, and the presence of basolateral elements in melanocytes suggests their polarized nature.

3.735 Multifunctional analysis of *Chlamydia*-specific genes in a yeast expression system
Sisko, J.L., Spaeth, K., Kumar, Y. And Valdivia, R.H.
Mol. Microbiol., ***60(1)****, 51-66 (2006)*

Our understanding of how obligate intracellular pathogens co-opt eukaryotic cellular functions has been limited by their intractability to genetic manipulation and by the abundance of pathogen-specific genes with no known functional homologues. In this report we describe a gene expression system to characterize proteins of unknown function from the obligate intracellular bacterial pathogen *Chlamydia trachomatis*. We have devised a homologous recombination-based cloning strategy to construct an ordered array of *Saccharomyces cerevisiae* strains expressing all *Chlamydia*-specific genes. These strains were screened to identify chlamydial proteins that impaired various yeast cellular functions or that displayed tropism towards eukaryotic organelles. In addition, to identify bacterial factors that are secreted into the host cell, recombinant chlamydial proteins were screened for reactivity towards antisera raised against vacuolar membranes purified from infected mammalian cells. We report the identification of 34 *C. trachomatis* proteins that impact yeast cellular functions or are tropic for a range of eukaryotic organelles including mitochondria, nucleus and cytoplasmic lipid droplets, and a new family of *Chlamydia*-specific proteins that are exported from the parasitopherous vacuole. The versatility of molecular manipulations and protein

expression in yeast allows for the rapid construction of comprehensive protein expression arrays to explore the function of pathogen-specific gene products from microorganisms that are difficult to genetically manipulate, grow in culture or too dangerous for routine analysis in the laboratory.

3.736 Rescue of cell growth by sphingosine with disruption of lipid microdomain formation in *Saccharomyces cerevisiae* deficient in sphingolipid biosynthesis
Tani, M., Khara, A. and Igarashi, Y.
Biochem. J., ***394***, *237-242 (2006)*

In the yeast *Saccharomyces cerevisiae*, sphingolipids are essential for cell growth. Inactivation of sphingolipid biosynthesis, such as by disrupting the serine palmitoyltransferase gene (*LCB2*), is lethal, but cells can be rescued by supplying an exogenous LCB (long-chain base) like PHS (phytosphingosine) or DHS (dihydrosphingosine). In the present study, supplying SPH (sphingosine), an unnatural LCB for yeast, similarly rescued the Δ*lcb2* cells, but only when SPH 1-phosphate production was inhibited by deleting the LCB kinase gene *LCB4*. Exogenously added SPH was adequately converted into phosphoinositol-containing complex sphingolipids. Interestingly, cells carrying SPH-based sphingolipids exhibited a defect in the association of Pma1p with Triton X-100-insoluble membrane fractions, and displayed sensitivities to both Ca^{2+} and hygromycin B. These results suggest that the SPH-based sphingolipids in these cells have properties that differ from those of the PHS- or DHS-based sphingolipids in regard to lipid microdomain formation, leading to abnormal sensitivities towards certain environmental stresses. The present paper is the first report showing that in sphingolipid-deficient *S. cerevisiae*, the requirement for LCB can be fulfilled by exogenous SPH, although this supplement results in failure of lipid microdomain formation.

3.737 Localization of a portion of the liver isoform of fatty-acid-binding protein (L-FABP) to peroxisomes
Antonenkov, V.D. et al
Biochem. J., ***394***, *475-484 (2006)*

The liver isoform of fatty-acid-binding protein (L-FABP) facilitates the cellular uptake, transport and metabolism of fatty acids and is also involved in the regulation of gene expressions and cell differentiation. Consistent with these functions, L-FABP is predominantly present in the cytoplasm and to a lesser extent in the nucleus; however, a significant portion of this protein has also been detected in fractions containing different organelles. More recent observations, notably on L-FABP-deficient mice, indicated a possible direct involvement of L-FABP in the peroxisomal oxidation of long-chain fatty acids. In order to clarify the links between L-FABP and peroxisomal lipid metabolism, we reinvestigated the subcellular distribution of the protein. Analytical subcellular fractionation by a method preserving the intactness of isolated peroxisomes, two-dimensional gel electrophoresis of peroxisomal matrix proteins combined with MS analysis, and immunoelectron microscopy of liver sections demonstrate the presence of L-FABP in the matrix of peroxisomes as a soluble protein. Peroxisomal L-FABP was highly inducible by clofibrate. The induction of L-FABP was accompanied by a marked increase in the binding capacity of peroxisomal matrix proteins for oleic acid and *cis*-parinaric acid. The peroxisomal β-oxidation of palmitoyl-CoA and acyl-CoA thioesterase activity were stimulated by L-FABP, indicating that the protein modulates the function of peroxisomal lipid-metabolizing enzymes. The possible role of intraperoxisomal L-FABP in lipid metabolism is discussed.

3.738 Internalized Pseudomonas exotoxin A can exploit multiple pathways to reach the endoplasmic reticulum
Smith, D.C. et al
Traffic, ***7(4)***, *379-393 (2006)*

Receptor-mediated internalization to the endoplasmic reticulum (ER) and subsequent retro-translocation to the cytosol are essential sequential processes required for the intoxication of mammalian cells by Pseudomonas exotoxin A (PEx). The toxin binds the α2-macroglobulin receptor/low-density lipoprotein receptor-related protein. Here, we show that in HeLa cells, PEx recruits a proportion of this receptor to detergent-resistant microdomains (DRMs). Uptake of receptor-bound PEx involves transport steps both directly from early endosomes to the *trans*-Golgi network (TGN) independently of Rab9 function and from late endosomes to the TGN in a Rab9-dependent manner. Furthermore, treatments that simultaneously perturb both Arf1-dependent and Rab6-dependent retrograde pathways show that PEx can use multiple routes to reach the ER. The Rab6-dependent route has only been described previously for cargo with lipid-sorting signals. These findings suggest that partial localization of PEx within DRM permits a choice of

trafficking routes consistent with a model that DRM-associated toxins reach the ER on a lipid-dependent sorting pathway whilst non-DRM-associated PEx exploits the previously characterized KDEL receptor-mediated uptake pathway. Thus, unexpectedly, an ER-directed toxin with a proteinaceous receptor shows promiscuity in its intracellular trafficking pathways, exploiting routes controlled by both lipid- and protein-sorting signals.

3.739 Dissecting Rotavirus Particle-Raft Interaction with Small Interfering RNAs: Insights into Rotavirus Transit through the Secretory Pathway
Cuadras, M.A., Bordier, B.B., Zambrano, J.L., Ludert, J.E. and Greenberg, H.B.
J. Virol., ***80(8)***, *3935-3946 (2006)*

Studies of rotavirus morphogenesis, transport, and release have shown that although these viruses are released from the apical surface of polarized intestinal cells before cellular lysis, they do not follow the classic exocytic pathway. Furthermore, increasing evidence suggests that lipid rafts actively participate in the exit of rotavirus from the infected cell. In this study, we silenced the expression of VP4, VP7, and NSP4 by using small interfering RNAs (siRNAs) and evaluated the effect of shutting down the expression of these proteins on rotavirus-raft interactions. Silencing of VP4 and NSP4 reduced the association of rotavirus particles with rafts; in contrast, inhibition of VP7 synthesis slightly affected the migration of virions into rafts. We found that inhibition of rotavirus migration into lipid rafts, by either siRNAs or tunicamycin, also specifically blocked the targeting of VP4 to rafts, suggesting that the association of VP4 with rafts is mostly mediated by the formation of viral particles in the endoplasmic reticulum (ER). We showed that two populations of VP4 exist, one small population that is independently targeted to rafts and a second large pool of VP4 whose association with rafts is mediated by particle formation in the ER. We also present evidence to support the hypothesis that assembly of VP4 into mature virions takes place in the late stages of transit through the ER. Finally, we analyzed the progression of rotavirus proteins in the exocytic pathway and found that VP4 and virion-assembled VP7 colocalized with ERGIC-53, suggesting that rotavirus particles transit through the intermediate compartment between the ER and the Golgi complex.

3.740 Rab1 Defines a Novel Pathway Connecting the Pre-Golgi Intermediate Compartment with the Cell Periphery
Sannerud, R. et al
Mol. Biol. Cell, ***17***, *1514-1526 (2006)*

The function of the pre-Golgi intermediate compartment (IC) and its relationship with the endoplasmic reticulum (ER) and Golgi remain only partially understood. Here, we report striking segregation of IC domains in polarized PC12 cells that develop neurite-like processes. Differentiation involves expansion of the IC and movement of Rab1-containing tubules to the growth cones of the neurites, whereas p58- and COPI-positive IC elements, like rough ER and Golgi, remain in the cell body. Exclusion of Rab1 effectors p115 and GM130 from the neurites further indicated that the centrifugal, Rab1-mediated pathway has functions that are not directly related to ER-to-Golgi trafficking. Disassembly of COPI coats did not affect this pathway but resulted in missorting of p58 to the neurites. Live cell imaging showed that green fluorescent protein (GFP)–Rab1A-containing IC elements move bidirectionally both within the neurites and cell bodies, interconnecting different ER exit sites and the *cis*-Golgi region. Moreover, in nonpolarized cells GFP-Rab1A-positive tubules moved centrifugally towards the cell cortex. Hydroxymethylglutaryl-CoA reductase, the key enzyme of cholesterol biosynthesis, colocalized with slowly sedimenting, Rab1-enriched membranes when the IC subdomains were separated by velocity sedimentation. These results reveal a novel pathway directly connecting the IC with the cell periphery and suggest that this Rab1-mediated pathway is linked to the dynamics of smooth ER.

3.741 Lysosomal trafficking and cysteine protease metabolism confer target-specific cytotoxicity by peptide-linked anti-CD30-auristatin conjugates
Kung, M.S. et al
J. Biol. Chem., ***281(15)***, *10540-10547 (2006)*

The chimeric anti-CD30 monoclonal antibody cAC10, linked to the antimitotic agents monomethyl auristatin E (MMAE) or F (MMAF), produces potent and highly CD30-selective anti-tumor activity *in vitro* and *in vivo*. These drugs are appended via a valine-citrulline (vc) dipeptide linkage designed for high stability in serum and conditional cleavage and putative release of fully active drugs by lysosomal cathepsins. To characterize the biochemical processes leading to effective drug delivery, we examined the intracellular trafficking, internalization, and metabolism of the parent antibody and two antibody-drug

conjugates, cAC10vc-MMAE and cAC10vc-MMAF, following CD30 surface antigen interaction with target cells. Both cAC10 and its conjugates bound to target cells and internalized in a similar manner. Subcellular fractionation and immunofluorescence studies demonstrated that the antibody and antibody-drug conjugates entering target cells migrated to the lysosomes. Trafficking of both species was blocked by inhibitors of clathrin-mediated endocytosis, suggesting that drug conjugation does not alter the fate of antibody-antigen complexes. Incubation of cAC10vc-MMAE or cAC10vc-MMAF with purified cathepsin B or with enriched lysosomal fractions prepared by subcellular fractionation resulted in the release of active, free drug. Cysteine protease inhibitors, but not aspartic or serine protease inhibitors, blocked antibody-drug conjugate metabolism and the ensuing cytotoxicity of target cells and yielded enhanced intracellular levels of the intact conjugates. These findings suggest that in addition to trafficking to the lysosomes, cathepsin B and perhaps other lysosomal cysteine proteases are requisite for drug release and provide a mechanistic basis for developing antibody-drug conjugates cleavable by intracellular proteases for the targeted delivery of anti-cancer therapeutics.

3.742 Reproducibility of LC-MS-based protein identification
Berg, M., Parbel, A., Pettersen, H., Fenyo, D. and Björkesten, L.
J. Exp. Botany, ***57(7)***, *1509-1514 (2006)*

Traditional analysis of liquid chromatography-mass spectrometry (LC-MS) data, typically performed by reviewing chromatograms and the corresponding mass spectra, is both time-consuming and difficult. Detailed data analysis is therefore often omitted in proteomics applications. When analysing multiple proteomics samples, it is usually only the final list of identified proteins that is reviewed. This may lead to unnecessarily complex or even contradictory results because the content of the list of identified proteins depends heavily on the conditions for triggering the collection of tandem mass spectra. Small changes in the signal intensity of a peptide in different LC-MS experiments can lead to the collection of a tandem mass spectrum in one experiment but not in another. Also, the quality of the tandem mass spectrometry experiments can vary, leading to successful identification in some cases but not in others. Using a novel image analysis approach, it is possible to achieve repeat analysis with a very high reproducibility by matching peptides across different LC-MS experiments using the retention time and parent mass over charge (*m/z*). It is also easy to confirm the final result visually. This approach has been investigated by using tryptic digests of integral membrane proteins from organelle-enriched fractions from *Arabidopsis thaliana* and it has been demonstrated that very highly reproducible, consistent, and reliable LC-MS data interpretation can be made.

3.743 The nuclear microspherule protein 58 is a novel RNA-binding protein that interacts with fragile X mental retardation in polyribosomal mRNPs from neurons
Davidovic, L. et al
Hum. Mol. Genet., ***15(9)***, *1525-1538 (2006)*

The fragile X syndrome, the leading cause of inherited mental retardation, is due to the inactivation of the fragile mental retardation 1 gene (*FMR1*) and the subsequent absence of its gene product FMRP. This RNA-binding protein is thought to control mRNA translation and its absence in fragile X cells leads to alteration in protein synthesis. In neurons, FMRP is thought to repress specific mRNAs during their transport as silent ribonucleoparticles (mRNPs) from the cell body to the distant synapses which are the sites of local synthesis of neuro-specific proteins. The mechanism by which FMRP sorts out its different mRNAs targets might be tuned by the intervention of different proteins. Using a yeast two-hybrid system, we identified MicroSpherule Protein 58 (MSP58) as a novel FMRP-cellular partner. In cell cultures, we found that MSP58 is predominantly present in the nucleus where it interacts with the nuclear isoform of FMRP. However, in neurons but not in glial cells, MSP58 is also present in the cytoplasmic compartment, as well as in neurites, where it co-localizes with FMRP. Biochemical evidence is given that MSP58 is associated with polyribosomal poly(A)+ mRNPs. We also show that MSP58, similar to FMRP, is present on polyribosomes prepared from synaptoneurosomes and that it behaves as an RNA-binding protein with a high affinity to the G-quartet structure. We propose that this novel cellular partner for FMRP escorts FMRP-containing mRNP from the nucleus and nucleolus to the somato-dendritic compartment where it might participate in neuronal translation regulation.

3.744 Overloading of stable and exclusion of unstable human superoxide dismutase-1 variants in mitochondria of murine amyotrophic lateral sclerosis models
Bergemalm, D. et al
J. Neurosci., ***26(16)***, *4147-4154 (2006)*

Mutants of human superoxide dismutase-1 (hSOD1) cause amyotrophic lateral sclerosis (ALS), and mitochondria are thought to be primary targets of the cytotoxic action. The high expression rates of hSOD1s in transgenic ALS models give high levels of the stable mutants G93A and D90A as well as the wild-type human enzyme, significant proportions of which lack Cu and the intrasubunit disulfide bond. The endogenous murine SOD1 (mSOD1) also lacks Cu and is disulfide reduced but is active and oxidized in mice expressing the low-level unstable mutants G85R and G127insTGGG. The possibility that the molecular alterations may cause artificial loading of the stable hSOD1s into mitochondria was explored. Approximately 10% of these hSOD1s were localized to mitochondria, reaching levels 100-fold higher than those of mSOD1 in control mice. There was no difference between brain and spinal cord and between stable mutants and the wild-type hSOD1. mSOD1 was increased fourfold in mitochondria from high-level hSOD1 mice but was normal in those with low levels, suggesting that the Cu deficiency and disulfide reduction cause mitochondrial overloading. The levels of G85R and G127insTGGG mutant hSOD1s in mitochondria were 100- and 1000-fold lower than those of stable mutants. Spinal cords from symptomatic mice contained hSOD1 aggregates covering the entire density gradient, which could contaminate isolated organelle fractions. Thus, high hSOD1 expression rates can cause artificial loading of mitochondria. Unstable low-level hSOD1s are excluded from mitochondria, indicating other primary locations of injury. Such models may be preferable for studies of ALS pathogenesis.

3.745 Cytoplasmic tails of SialT2 and GalNacT impose their respective proximal and distal Golgi localization

Uliana, A.S., Giraudo, C.G. and Maccioni, H.J.F.
Traffic, ***7***, *604-612 (2006)*

Complex glycolipid synthesis is catalyzed by different glycosyltransferases resident of the Golgi complex. Most of them are type II membrane proteins comprising a lumenal, C-terminal domain linked to an N-terminal domain (Ntd) constituted by a short cytoplasmic tail (ct), a transmembrane, and a lumenal stem regions. They concentrate selectively in different sub-Golgi compartments, in an overlapped manner, acting in succession in the addition of sugars to acceptor glycolipids. The Ntds are sufficient to localize glycosyltransferases in the Golgi complex, but it is not clear whether they also confer selective concentration in sub-Golgi compartments. Here, we studied whether the Ntd of SialT2, localized in the proximal Golgi, and the one of GalNAcT, a *trans*/TGN Golgi-concentrated enzyme, concentrate reporter proteins in the corresponding sub-Golgi compartment. The sub-Golgi concentration of the Ntds fused to spectral variants of the GFP was determined in CHO-K1 cells from their behavior upon addition of brefeldin A. Fluorescence microscopy and subcellular fractionation showed that the SialT2 Ntd concentrates in a proximal sub-Golgi compartment – and that of GalNAcT in TGN elements. Exchanging the transmembrane region and the cts of SialT2 and GalNAcT indicates that information for proximal or distal Golgi concentration is associated with the cts.

3.746 rAAV2 traffics through both the late and the recycling endosomes in a dose-dependent fashion

Ding, W., Zhang, L.N., Yeaman, C. and Engelhardt, J.F.
Mol. Ther., ***13(4)***, *671-682 (2006)*

Inefficient trafficking of recombinant adeno-associated virus type-2 (rAAV2) to the nucleus is a major barrier for transduction. Using imaging and subcellular fractionation techniques, we evaluated the extent of rAAV2 movement through the late (Rab7) and recycling (Rab11) endosomes. Following rAAV2 infection of HeLa cells, immunoisolation of HA–Rab7- or HA–Rab11-tagged endosomes and intracellular colocalization of Cy3-labeled rAAV2 with EGFP–Rab7 or EGFP–Rab11 markers demonstrated dose-dependent trafficking of rAAV2 through the recycling and late endosomal compartments. At low multiplicities of infection (m.o.i. 100 genomes/cell), rAAV2 predominantly trafficked to the Rab7 compartment. In contrast, rAAV2 predominantly trafficked to the recycling endosome at 100-fold higher m.o.i. siRNA studies inhibiting either Rab7 or Rab11 demonstrated that reducing Rab11 protein levels more significantly inhibited rAAV2 transduction on a per genome basis compared to inhibition of Rab7. Dose–response curves, comparing the m.o.i. of AV2Luc infection to relative transduction, also supported the hypothesis that viral movement through the Rab11 compartment at high m.o.i. is more competent for transgene expression ($\sim$100-fold) than virus that moves through the Rab7 compartment at low m.o.i. These findings suggest that strategies to shunt viral movement from the late to the recycling endosome may be effective at increasing viral transduction for gene therapy.

3.747 Mapping the *Arabidopsis* organelle proteome
Dunkley, T.P.J. et al
*PNAS, **103(17)**, 6518-6523 (2006)*

A challenging task in the study of the secretory pathway is the identification and localization of new proteins to increase our understanding of the functions of different organelles. Previous proteomic studies of the endomembrane system have been hindered by contaminating proteins, making it impossible to assign proteins to organelles. Here we have used the localization of organelle proteins by the isotope tagging technique in conjunction with isotope tags for relative and absolute quantitation and 2D liquid chromatography for the simultaneous assignment of proteins to multiple subcellular compartments. With this approach, the density gradient distributions of 689 proteins from *Arabidopsis thaliana* were determined, enabling confident and simultaneous localization of 527 proteins to the endoplasmic reticulum, Golgi apparatus, vacuolar membrane, plasma membrane, or mitochondria and plastids. This parallel analysis of endomembrane components has enabled protein steady-state distributions to be determined. Consequently, genuine organelle residents have been distinguished from contaminating proteins and proteins in transit through the secretory pathway.

3.748 Opposite effect of caveolin-1 in the metabolism of high-density and low-density lipoproteins
Truong, T.Q., Aubin, D., Bourgeois, P., Falstrault, L. and Brisette, L.
*Biochim. Biophys. Acta, **1761**, 24-36 (2006)*

Receptors of the scavenger class B family were reported to be localized in caveolae, the cell surface microdomains rich in free cholesterol and glycosphyngolipids, which are characterized by the presence of caveolin-1. Parenchymal hepatic and hepatoma HepG2 cells express very low levels of caveolin-1. In the present study, stable transformants of HepG2 cells expressing caveolin-1 were generated to address the effect of caveolin-1 on receptor activity. Compared to normal cells, these cells show higher ^{125}I-bovine serum albumin (BSA) uptake and cholesterol efflux, two indicators of functional caveolae. By immunoprecipitation, cell fractionation and confocal analyses, we found that caveolin-1 is well colocalized with the cluster of differentiation-36 (CD36) and the low-density lipoprotein (LDL) receptor (LDLr) but to a lesser extent with the scavenger receptor class B type I (SR-BI) in HepG2 cells expressing caveolin-1. However, caveolin-1 expression favors the dimerization of SR-BI. Two clones of cells expressing caveolin-1 were investigated for their lipoprotein metabolism activity. Compared to normal cells, these cells show a 71–144% increase in ^{125}I-LDL degradation. The analysis of the cholesteryl esters (CE)-selective uptake (CE association minus protein association) revealed that the expression of caveolin-1 in HepG2 cells decreases by 59%–73% LDL-CE selective uptake and increases high-density lipoprotein (HDL)-CE selective uptake by 44%–66%. We conclude that the expression of caveolin-1 in HepG2 cells moves the balance of LDL degradation/CE selective uptake towards degradation and favors HDL-CE selective uptake. Thus, in the normal hepatic parenchymal situation where caveolin-1 is poorly expressed, LDL-CE selective uptake is the preferred pathway.

3.749 Nephrin ectodomain engagement results in Src kinase activation, nephrin phosphorylation, Nck recruitment, and actin polymerization
Verma, R. et al
*J. Clin. Invest., **116(5)**, 1346-1359 (2006)*

A properly established and maintained podocyte intercellular junction, or slit diaphragm, is a necessary component of the selective permeability barrier of the kidney glomerulus. The observation that mutation or deletion of the slit diaphragm transmembrane protein nephrin results in failure of podocyte foot process morphogenesis and concomitant proteinuria first suggested the hypothesis that nephrin serves as a component of a signaling complex that directly integrates podocyte junctional integrity with cytoskeletal dynamics. The observations made herein provide the first direct evidence to our knowledge for a phosphorylation-mediated signaling mechanism by which this integrative function is derived. Our data support the model that during podocyte intercellular junction formation, engagement of the nephrin ectodomain induces transient Fyn catalytic activity that results in nephrin phosphorylation on specific nephrin cytoplasmic domain tyrosine residues. We found that this nephrin phosphorylation event resulted in recruitment of the SH2–SH3 domain–containing adapter protein Nck and assembly of actin filaments in an Nck-dependent fashion. Considered in the context of the role of nephrin family proteins in other organisms and the integral relationship of actin dynamics and junction formation, these observations establish a function for nephrin in regulating actin cytoskeletal dynamics.

3.750 The Interaction between Cytoplasmic Prion Protein and the Hydrophobic Lipid Core of Membrane Correlates with Neurotoxicity

Wang, X., Wang, F., Arterburn, L., Wollmann, R. and Ma, J.
J. Biol. Chem., ***281(19)***, *13559-13565 (2006)*

Prion protein (PrP), normally a cell surface protein, has been detected in the cytosol of a subset of neurons. The appearance of PrP in the cytosol could result from either retro-translocation of misfolded PrP from the endoplasmic reticulum (ER) or impaired import of PrP into the ER. Transgenic mice expressing cytoplasmic PrP (cyPrP) developed neurodegeneration in cerebellar granular neurons, although no detectable pathology was observed in other brain regions. In order to understand why granular neurons in the cerebellum were most susceptible to cyPrP-induced degeneration, we investigated the subcellular localization of cyPrP. Interestingly, we found that cyPrP is membrane-bound. In transfected cells, it binds to the ER and plasma/endocytic vesicular membranes. In transgenic mice, it is associated with synaptic and microsomal membranes. Furthermore, the cerebellar neurodegeneration in transgenic mice correlates with the interaction between cyPrP and the hydrophobic lipid core of the membrane but not with either the aggregation status or the dosage of cyPrP. These results suggest that lipid membrane perturbation could be a cellular mechanism for cyPrP-induced neurotoxicity and explain the seemingly conflicting results concerning cyPrP.

3.751 Differential expression of nuclear AT1 receptors and angiotensin II within the kidney of the male congenic mRen2.Lewis rat

Pendergrass, K.D., Averill, D.B., Ferrario, C.M., Diz, D.I. and Chappell, M.C.
Am. J. Physiol. Renal Physiol., ***290***, *F1497-F1506 (2006)*

We established a new congenic model of hypertension, the mRen(2).Lewis rat and assessed the intracellular expression of angiotensin peptides and receptors in the kidney. The congenic strain was established from the backcross of the (mRen2)27 transgenic rat that expresses the mouse renin 2 gene onto the Lewis strain. The 20-wk-old male congenic rats were markedly hypertensive compared with the Lewis controls (systolic blood pressure: 195 ± 2 vs. 107 ± 2 mmHg, $P < 0.01$). Although plasma ANG II levels were not different between strains, circulating levels of ANG-(1–7) were 270% higher and ANG I concentrations were 40% lower in the mRen2.Lewis rats. In contrast, both cortical (CORT) and medullary (MED) ANG II concentrations were 60% higher in the mRen2.Lewis rats, whereas tissue ANG I was 66 and 84% lower in CORT and MED. For both strains, MED ANG II, ANG I, and ANG-(1–7) were significantly higher than CORT levels. Intracellular ANG II binding distinguished nuclear (NUC) and plasma membrane (PM) receptor using the ANG II radioligand ^{125}I-sarthran. Isolated CORT nuclei exhibited a high density (B_{max} >200 fmol/mg protein) and affinity for the sarthran ligand (K_D<0.5 nM); the majority of these sites (>95%) were the AT_1 receptor subtype. CORT ANG II receptor B_{max} and K_D values in nuclei were 75 and 50% lower, respectively, for the mRen2.Lewis vs. the Lewis rats. In the MED, the PM receptor density (Lewis: 50 ± 4 vs. mRen2.Lewis: 21 ± 5 fmol/mg protein) and affinity (Lewis: 0.31 ± 0.1 vs. 0.69 ± 0.1 nM) were lower in the mRen2.Lewis rats. In summary, the hypertensive mRen2.Lewis rats exhibit higher ANG II in both CORT and MED regions of the kidney. Evaluation of intracellular ANG II receptors revealed lower CORT NUC and MED PM AT_1 sites in the mRen2.Lewis. The downregulation of AT_1 sites in the mRen2.Lewis rats may reflect a compensatory response to dampen the elevated levels of intrarenal ANG II.

3.752 MPV17 encodes an inner mitochondrial membrane protein and is mutated in infantile hepatic mitochondrial DNA depletion

Spinazzola, A. et al
Nature Genetics, ***38(5)***, *570-575 (2006)*

The mitochondrial (mt) DNA depletion syndromes (MDDS) are genetic disorders characterized by a severe, tissue-specific decrease of mtDNA copy number, leading to organ failure. There are two main clinical presentations: myopathic (OMIM 609560) and hepatocerebral1 (OMIM 251880). Known mutant genes, including TK2 (ref. 2), SUCLA2 (ref. 3), DGUOK (ref. 4) and POLG 5, 6, account for only a fraction of MDDS cases7. We found a new locus for hepatocerebral MDDS on chromosome 2p21-23 and prioritized the genes on this locus using a new integrative genomics strategy. One of the top-scoring candidates was the human ortholog of the mouse kidney disease gene Mpv17 (ref. 8). We found disease-segregating mutations in three families with hepatocerebral MDDS and demonstrated that, contrary to the alleged peroxisomal localization of the MPV17 gene product9, MPV17 is a mitochondrial inner membrane

protein, and its absence or malfunction causes oxidative phosphorylation (OXPHOS) failure and mtDNA depletion, not only in affected individuals but also in Mpv17-/- mice.

3.753 Gas1 Is Related to the Glial Cell-derived Neurotrophic Factor Family Receptors αand Regulates Ret Signaling
Cabrera, J.R. et al
J. Biol. Chem., ***281(20)***, *14330-14339 (2006)*

The growth arrest-specific gene 1 (Gas1) protein has been proposed to function during development as an inhibitor of growth and a mediator of cell death and is also re-expressed in adult neurons during excitotoxic insult. Here we have demonstrated that the Gas1 protein shows high structural similarity to the glial cell-derived neurotrophic factor (GDNF) family receptors α, which mediate GDNF responses through the receptor tyrosine kinase Ret. We found that Gas1 binds Ret in a ligand-independent manner and sequesters Ret in lipid rafts. Signaling downstream of Ret is thus modified through a mechanism that involves the adaptor protein Shc as well as ERK, eventually blocking Akt activation. Consequently, when Gas1 is induced, Ret-mediated GDNF-dependent survival effects are compromised. The growth arrest-specific gene 1 (Gas1) protein has been proposed to function during development as an inhibitor of growth and a mediator of cell death and is also re-expressed in adult neurons during excitotoxic insult. Here we have demonstrated that the Gas1 protein shows high structural similarity to the glial cell-derived neurotrophic factor (GDNF) family receptors α, which mediate GDNF responses through the receptor tyrosine kinase Ret. We found that Gas1 binds Ret in a ligand-independent manner and sequesters Ret in lipid rafts. Signaling downstream of Ret is thus modified through a mechanism that involves the adaptor protein Shc as well as ERK, eventually blocking Akt activation. 3.754 Sequence Requirements for Localization of Human Cytomegalovirus Tegument Protein pp28 to the Virus Assembly Compartment and for Assembly of Infectious Virus
Seo, J-Y. and Britt, W.J.
J. Virol., ***80(11)***, *5611-5626 (2006)*

The human cytomegalovirus UL99 open reading frame encodes a 190-amino-acid (aa) tegument protein, pp28, that is myristoylated and phosphorylated. pp28 is essential for assembly of infectious virus, and nonenveloped virions accumulate in the cytoplasm of cells infected with recombinant viruses with a UL99 deletion. pp28 is localized to the endoplasmic reticulum-Golgi intermediate compartment (ERGIC) in transfected cells, while in infected cells, it is localized together with other virion proteins in a juxtanuclear compartment termed the assembly compartment (AC). We investigated the sequence requirements for pp28 trafficking to the AC and assembly of infectious virus. Our studies indicated that the first 30 to 35 aa were required for localization of pp28 to the ERGIC in transfected cells. Mutant forms of pp28 containing only the first 35 aa localized with other virion structural proteins to cytoplasmic compartments early in infection, but localization to the AC at late times required a minimum of 50 aa. In agreement with previous reports, we demonstrated that the deletion of a cluster of acidic amino acids (aa 44 to 59) prevented wild-type trafficking of pp28 and recovery of infectious virus. A recombinant virus expressing only the first 50 aa was replication competent, and this mutant, pp28, localized to the AC in cells infected with this virus. These findings argued that localization of pp28 to the AC was essential for assembly of infectious virus and raised the possibility that amino acids in the amino terminus of pp28 have additional roles in the envelopment and assembly of the virion other than simply localizing pp28 to the AC.

3.755 Detergent-free caveolae proteome suggests an interaction with ER and mitochondria
McMahon, K-A. et al
Proteomics, ***6***, *143-152 (2006)*

Recent proteomic studies of detergent resistant membrane fractions have begun to characterize the protein composition of caveolae and lipid rafts. The methods used in most of these studies, however, are not able to distinguish between plasma membrane and internal membrane lipid domains. Here we used a non-detergent method for obtaining fractions enriched in caveolae derived from the plasma membrane of multiple cell types. Unexpectedly, the proteins in the caveolae proteome suggest these lipid domains may interact with elements of ER and mitochondria. A comparison of the partial proteome we obtained with other published reports identifies 26 proteins that are candidate marker proteins for identifying caveolae in multiple cell types.

3.756 Deletion of SERP1/RAMP4, a Component of the Endoplasmic Reticulum (ER) Translocation Sites, Leads to ER Stress
Hori, O. et al
Mol. Cell. Biol., ***26(11)****, 4257-4267 (2006)*

Stress-associated endoplasmic reticulum (ER) protein 1 (SERP1), also known as ribosome-associated membrane protein 4 (RAMP4), is a Sec61-associated polypeptide that is induced by ER stress. SERP1$^{-/-}$ mice, made by targeted gene disruption, demonstrated growth retardation, increased mortality, and impaired glucose tolerance. Consistent with high levels of SERP1 expression in pancreas, pancreatic islets from SERP1$^{-/-}$ mice failed to rapidly synthesize proinsulin in response to a glucose load. In addition, reduced size and enhanced ER stress were observed in the anterior pituitary of SERP1$^{-/-}$ mice, and growth hormone production was slowed in SERP1$^{-/-}$ pituitary after insulin stimulation. Experiments using pancreatic microsomes revealed aberrant association of ribosomes and the Sec61 complex and enhanced ER stress in SERP1$^{-/-}$ pancreas. In basal conditions, the Sec61 complex in SERP1$^{-/-}$ microsomes was more cofractionated with ribosomes, compared with SERP1$^{+/+}$ counterparts, in high-salt conditions. In contrast, after glucose stimulation, the complex showed less cofractionation at an early phase (45 min) but more at a later phase (120 min). Although intracellular insulin/proinsulin levels were not significantly changed in both genotypes, these results suggest that subtle changes in translocation efficiency play an important role in the regulation of ER stress and rapid polypeptide synthesis.

3.757 DHCR24-Knockout Embryonic Fibroblasts Are Susceptible to Serum Withdrawal-Induced Apoptosis Because of Dysfunction of Caveolae and Insulin-Akt-Bad Signaling
Lu, X. et al
Endocrinology, ***147(6)****, 3123-3132 (2006)*

The DHCR24 gene encodes an enzyme catalyzing the last step of cholesterol biosynthesis, the conversion of desmosterol to cholesterol. To elucidate the physiological significance of cholesterol biosynthesis in mammalian cells, we investigated proliferation of mouse embryonic fibroblasts (MEFs) prepared from DHCR24$^{-/-}$ mice. Both DHCR24$^{-/-}$ and wild-type MEFs proliferated in the presence of serum in culture media. However, the inhibition of external cholesterol supply by serum withdrawal induced apoptosis of DHCR24$^{-/-}$ MEFs, which was associated with a marked decrease in the intracellular and plasma membrane cholesterol levels, Akt inactivation, and Bad dephosphorylation. Insulin is an antiapoptotic factor capable of stimulating the Akt-Bad cascade, and its receptor (IR) is enriched in caveolae, cholesterol-rich microdomains of plasma membrane. We thus analyzed the association of IR and caveolae in the cholesterol-depleted MEFs. Subcellular fractionation and immunocytochemical analyses revealed that the IR and caveolin-1 contents were markedly reduced in the caveolae fraction of the MEFs, suggesting the disruption of caveolae, and that large amounts of IR were present apart from caveolin-1 on plasma membrane, indicating the uncoupling of IR with caveolae. Consistent with these findings, insulin-dependent phosphorylations of insulin receptor substrate-1, Akt, and Bad were impaired in the cholesterol-depleted MEFs. However, this impairment was partial because treatment of the MEFs with insulin restored Akt activation and prevented apoptosis. Cholesterol supply also prevented apoptosis. These results demonstrate that the cellular cholesterol biosynthesis is critical for the activation and maintenance of the Akt-Bad cell survival cascade in response to growth factors such as insulin.

3.758 Membrane vesicles shed by *Legionella pneumophila* inhibit fusion of phagosomes with lysosomes
Fernandez-Moreira, E., Helbig, J.H. and Swanson, M.S.
*Infect. Immun.,****74(6)****, 3285-3295 (2006)*

When cultured in broth to the transmissive phase, *Legionella pneumophila* infects macrophages by inhibiting phagosome maturation, whereas replicative-phase cells are transported to the lysosomes. Here we report that the ability of *L. pneumophila* to inhibit phagosome-lysosome fusion correlated with developmentally regulated modifications of the pathogen's surface, as judged by its lipopolysaccharide profile and by its binding to a sialic acid-specific lectin and to the hydrocarbon hexadecane. Likewise, the composition of membrane vesicles shed by *L. pneumophila* was developmentally regulated, based on binding to the lectin and to the lipopolysaccharide-specific monoclonal antibody 3/1. Membrane vesicles were sufficient to inhibit phagosome-lysosome fusion by a mechanism independent of type IV secretion, since only ~25% of beads suspended with or coated by vesicles from transmissive phase wild type or *dotA* secretion mutants colocalized with lysosomal probes, whereas ~75% of beads were lysosomal when untreated or presented with vesicles from the *L. pneumophila letA* regulatory mutant or *E. coli*. As

observed previously for *L. pneumophila* infection of mouse macrophages, vesicles inhibited phagosome-lysosome fusion only temporarily; by 10 h after treatment with vesicles, macrophages delivered ~72% of ingested beads to lysosomes. Accordingly, in the context of the epidemiology of the pneumonia Legionnaires' disease and virulence mechanisms of *Leishmania* and *Mycobacteria*, we discuss a model here in which *L. pneumophila* developmentally regulates its surface composition and releases vesicles into phagosomes that inhibit their fusion with lysosomes.

3.759 Mutational analysis of the Lem3p-Dnf1p putative phospholipid-translocating P-type ATPase reveals novel regulatory roles for Lem3p and a carboxyl-terminal region of Dnf1p independent of the phospholipid-translocating activity of Dnf1p in yeast
Noji, T. et al
Biochem. Biophys. Res. Comm., ***344***, *323-331 (2006)*

Lem3p-Dnf1p is a putative aminophospholipid translocase (APLT) complex that is localized to the plasma membrane; Lem3p is required for Dnf1p localization to the plasma membrane. We have identified *lem3* mutations, which did not affect formation or localization of the Lem3p-Dnf1p complex, but caused a synthetic growth defect with the null mutation of *CDC50*, a structurally and functionally redundant homologue of *LEM3*. Interestingly, these *lem3* mutants exhibited nearly normal levels of NBD-labeled phospholipid internalization across the plasma membrane, suggesting that Lem3p may have other functions in addition to regulation of the putative APLT activity of Dnf1p at the plasma membrane. Similarly, deletion of the COOH-terminal cytoplasmic region of Dnf1p affected neither the localization nor the APLT activity of Dnf1p at the plasma membrane, but caused a growth defect in the *cdc50Δ* background. Our results suggest that the Lem3p-Dnf1p complex may play a role distinct from its plasma membrane APLT activity when it substitutes for the Cdc50p-Drs2p complex, its redundant partner in the endosomal/*trans*-Golgi network compartments.

3.760 The rab exchange factor Sec2p reversibly associates with the exocyst
Medkova, M., France, Y.E., Coleman, J. and Novick, P.
Mol. Biol. Cell, ***17(6)****, 2757-2769 (2006)*

Activation of the rab GTPase, Sec4p, by its exchange factor, Sec2p, is needed for polarized transport of secretory vesicles to exocytic sites and for exocytosis. A small region in the C-terminal half of Sec2p regulates its localization. Loss of this region results in temperature-sensitive growth and the depolarized accumulation of secretory vesicles. Here, we show that Sec2p associates with the exocyst, an octameric effector of Sec4p involved in tethering secretory vesicles to the plasma membrane. Specifically, the exocyst subunit Sec15p directly interacts with Sec2p. This interaction normally occurs on secretory vesicles and serves to couple nucleotide exchange on Sec4p to the recruitment of the Sec4p effector. The mislocalization of Sec2p mutants correlates with dramatically enhanced binding to the exocyst complex. We propose that Sec2p is normally released from the exocyst after vesicle tethering so that it can recycle onto a new round of vesicles. The mislocalization of Sec2p mutants results from a failure to be released from Sec15p, blocking this recycling pathway.

3.761 Caveolin-1 is required for fatty acid translocase (FAT/CD36) localization and function at the plasma membrane of mouse embryonic fibroblasts
Ring, A., Le Lay, S., pohl, J., Verkade, P. and Stremmel, W.
Biochim. Biophys. Acta, ***1761****, 416-423 (2006)*

Several lines of evidence suggest that lipid rafts are involved in cellular fatty acid uptake and influence fatty acid translocase (FAT/CD36) function. However, it remains unknown whether caveolae, a specialized raft type, are required for this mechanism. Here, we show that wild-type (WT) mouse embryonic fibroblasts (MEFs) and caveolin-1 knockout (KO) MEFs, which are devoid of caveolae, have comparable overall expression of FAT/CD36 protein but altered subcellular FAT/CD36 localization and function. In WT MEFs, FAT/CD36 was isolated with both lipid raft enriched detergent-resistant membranes (DRMs) and detergent-soluble membranes (DSMs), whereas in cav-1 KO cells it was exclusively associated with DSMs. Subcellular fractionation demonstrated that FAT/CD36 in WT MEFs was localized intracellularly and at the plasma membrane level while in cav-1 KO MEFs it was absent from the plasma membrane. This mistargeting of FAT/CD36 in cav-1 KO cells resulted in reduced fatty acid uptake compared to WT controls. Adenoviral expression of caveolin-1 in KO MEFs induced caveolae formation, redirection of FAT/CD36 to the plasma membrane and rescue of fatty acid uptake. In conclusion, our data provide

evidence that caveolin-1 is necessary to target FAT/CD36 to the plasma membrane. Caveolin-1 may influence fatty acid uptake by regulating surface availability of FAT/CD36.

3.762 Phosphorylation of phototransduction GAP RGS9-1 depends on the α isoform of protein kinase C
Wang, Q., Hu, G., Leitges, M. and Wensel, T.G.
Invest. Ophthalmol. Vis. Sci., ***47***, *E-abstract 822 (2006)*

Purpose: To investigate the regulation of the photoreceptor–specific GTPase Accelerating Protein (GAP) RGS9–1 by PKCα. Normal light response kinetics require both RGS9–1 and its membrane anchor R9AP, whose interactions have been previously shown to be modified by a light–inhibited phosphorylation on Ser^{475} of RGS9–1 catalyzed by one or more isozymes of protein kinase C (PKC).
Methods: PKCα–/– and wild–type mice were compared. The presence of PKCα in mouse rod outer segments was examined by western blot of purified rod outer segments. The localization of PKCα to rod outer segments was confirmed by analysis of fractions collected from two successive sucrose gradients and iso–osmotic **OptiPrep** gradient purification. The amount of PKCα in purified intact rod outer segments was determined by quantitative western blot of rod outer segments and retina lysates. *In vitro* phosphorylation of RGS9–1 in rod outer segments by endogenous PKCα was detected by kinase assays. *In vivo* light–regulated phosphorylation of RGS9–1 at Ser^{475} was assessed by immunoprecipitation of RGS9–1 from mice retinas and followed by western blot using Ser^{475}–phosphate–specific antibody.
Results: PKCα immuno–reactivity is present in wild–type mouse rod outer segments but missing in those of PKCα –/– mice. It consistently co–purifies with rod outer segments. Approximately 20% of the total retinal PKCα pool is in mouse rod outer segments. PKCα knockouts do not exhibit the light–sensitive phosphorylation of RGS9–1 on PKC target site Ser^{475} that is observed in wild–type mice and show slower RGS9–1 Ser^{475} phosphorylation *in vitro*.
Conclusion: PKCα immuno–reactivity in photoreceptor cells is genuine and not due to cross–activity and contamination. PKCα is essential for light–sensitive RGS9–1 Ser^{475} phosphorylation. These results indicate that rod outer segments contain modest levels of PKCα, and this enzyme is responsible for regulation of the R9AP–RGS9–1 membrane complex by Ser^{475} phosphorylation, thus likely regulating the rate–limiting reaction in vision.

3.763 Regulation of RPE phagocytosis by integrin receptor-tetraspanin surface membrane domains
Finnemann, S.C. and Chang, Y.
Invest. Ophthalmol. Vis. Sci., ***47***, *e-abstract 5879 (2006)*

Purpose: Retinal pigment epithelial (RPE) cells depend on αvß5 integrin receptors and their downstream signaling pathways to maximize their phagocytic activity following circadian photoreceptor outer segment (POS) shedding in the retina. We hypothesize that the activity of αvß5 integrin itself may be regulated in the RPE to synchronize phagocytosis. Integrin receptors may associate with proteins of the tetraspanin family in specialized membrane microdomains to control integrin signaling. Here, we test whether tetraspanins functionally interact with αvß5 integrin in RPE cells. Methods: RT–PCRs and immunoblotting established tetraspanin expression in RPE cells *in vitro* and *in vivo*. We used confocal microscopy following live cell labeling with receptor antibodies and choleratoxin B to co–localize αvß5 integrin and tetraspanins to plasma membrane sub–domains at the apical surface of the RPE. We used **optiprep** gradient fractionation of RPE cell lysates and co–immunoprecipitation assays to further test subcellular co–fractionation of tetraspanins and αvß5 integrin. We used isolated POS fragments in quantitative uptake assays to determine effects of surface cholesterol depletion, tetraspanin antibody blocking and tetraspanin overexpression on the phagocytic function of RPE cells in culture. **Results:** We found that tetraspanins CD9, CD63 and CD81 localize to the apical, phagocytic surface of RPE cells in culture. CD81 partially co–localized with αvß5 integrin. Furthermore, we identified CD81 in a complex with αvß5 integrin in RPE cells in culture and in intact retina. CD81 co–fractionated with αvß5 in low–density membrane domains of RPE cell lysates. Cholesterol depletion, which altered CD81 and αvß5 surface distribution, as well as specific inhibition of CD81 reduced POS phagocytosis by human and rat RPE cell cultures. In contrast, CD81 overexpression increased POS phagocytosis. **Conclusions:** Our results demonstrate that the apical plasma membrane tetraspanin CD81 regulates the phagocytic activity of the RPE. Functional interaction with tetraspanins including CD81 and microdomain recruitment may contribute to the temporal control of αvß5 integrin receptor signaling in the RPE that is necessary for rhythmic phagocytosis of shed POS. Ongoing experiments study CD81 and integrin αvß5 complex formation and distribution during active RPE phagocytosis *in vitro* and *in vivo*.

3.764 Lipid raft-based membrane compartmentation of a plant transport protein expressed in *Saccharomyces cerevisiae*

Grossmann, G., Opekarova, M., Novakova, L., Stolz, J. and Tanner, W.
*Eukaryot. Cell, **5(6)**, 945-953 (2006)*

The hexose-proton symporter HUP1 shows a spotty distribution in the plasma membrane of the green alga *Chlorella kessleri*. *Chlorella* cannot be transformed so far. To study the membrane localization of the HUP1 protein in detail, the symporter was fused to green fluorescent protein (GFP) and heterologously expressed in *Saccharomyces cerevisiae* and *Schizosaccharomyces pombe*. In these organisms, the HUP1 protein has previously been shown to be fully active. The GFP fusion protein was exclusively targeted to the plasma membranes of both types of fungal cells. In *S. cerevisiae*, it was distributed nonhomogenously and concentrated in spots resembling the patchy appearance observed previously for endogenous H^+ symporters. It is documented that the *Chlorella* protein colocalizes with yeast proteins that are concentrated in 300-nm raft-based membrane compartments. On the other hand, it is completely excluded from the raft compartment housing the yeast H^+/ATPase. As judged by their solubilities in Triton X-100, the HUP1 protein extracted from *Chlorella* and the GFP fusion protein extracted from *S. cerevisiae* are detergent-resistant raft proteins. *S. cerevisiae* mutants lacking the typical raft lipids ergosterol and sphingolipids showed a homogenous distribution of HUP1-GFP within the plasma membrane. In an ergosterol synthesis (*erg6*) mutant, the rate of glucose uptake was reduced to less than one-third that of corresponding wild-type cells. In *S. pombe*, the sterol-rich plasma membrane domains can be stained in vivo with filipin. *Chlorella* HUP1-GFP accumulated exactly in these domains. Altogether, it is demonstrated here that a plant membrane protein has the property of being concentrated in specific raft-based membrane compartments and that the information for its raft association is retained between even distantly related organisms.

3.765 Assembly of infectious HIV-1 in human epithelial and T-lymphoblastic cell lines

Grigorov, B., Arcanger, F., Roingeard, P., Darlix, J-L. and Muriaux, D.
*J. Mol. Biol., **359**, 848-862 (2006)*

The canonical view of the ultimate steps of HIV-1 replication is that virus assembly and budding are taking place at the plasma membrane of infected cells. Surprisingly, recent studies revealed that these steps also occur on endosomal membranes in the interior of infected cells, such as macrophages. This prompted us to revisit the site of HIV-1 assembly in human epithelial-like cells and in infected human T-lymphoblastic cells. To address this question, we investigated the intracellular location of the major viral structural components of HIV-1, namely Gag, Env and the genomic RNA. Using a sub-cellular fractionation method, as well as immuno-confocal and electron microscopy, we show that Gag, the Env glycoproteins and the genomic RNA accumulate in late endosomes that contain infectious HIV-1 particles. In epithelial-like 293T cells, HIV-1 assembles and buds both at the plasma membrane and in endosomes, while in chronically infected human T lymphocytes, viral assembly mostly occurs within the cell where large amounts of infectious virions accumulate in endosomal compartments. In addition, HIV-1 release could be enhanced by ionomycin, a drug stimulating calcium-dependent exocytosis. These results favour the view that newly made Gag molecules associate with the genomic RNA in the cytosol, then viral core complexes can be targeted to late endosomes together with Env, where infectious HIV-1 are made and subsequently released by exocytosis.

3.766 Thyroid hormone receptor isoforms localize to cardiac mitochondrial matrix with potential for binding to receptor elements on mtDNA

Morrish, F. et al
*Mitochondrion, **6(3)**, 143-148 (2006)*

Thyroid hormone (T_3) rapidly promotes both nuclear and mitochondrial DNA transcription in cardiomyocytes, suggesting that T3 directly binds and activates mitochondrial genes. We showed for the first time mitochondrial localization for multiple TRα isoforms in heart, including truncated versions. Additionally, we demonstrated novel mitochondrial localization for versions of $TR\alpha_2$, the dominant negative isoform lacking a functional ligand-binding domain. We also confirmed by electromobility shift assays, that $TR\alpha_2$ in mitochondrial extracts binds to thyroid receptor response elements present in the 12S rRNA (DRO) and D-loop region (DR2) of mitochondrial DNA. Thus, TRα isoforms may directly regulate T_3 responses at mtDNA in the heart.

3.767 Intracellular ATP-sensitive K^+ channels in mouse pancreata beta cells: against a role in organelle cation homeostasis
Varadi, A. et al
*Diabetologia, **49**, 1567-1577 (2006)*

Aims/hypothesis ATP-sensitive K^+ (K_{ATP}) channels located on the beta cell plasma membrane play a critical role in regulating insulin secretion and are targets for the sulfonylurea class of antihyperglycaemic drugs. Recent reports suggest that these channels may also reside on insulin-containing dense-core vesicles and mitochondria. The aim of this study was to explore these possibilities and to test the hypothesis that vesicle-resident channels play a role in the control of organellar Ca^{2+} concentration or pH.
Methods To quantify the subcellular distribution of the pore-forming subunit Kir6.2 and the sulfonylurea binding subunit SUR1 in isolated mouse islets and clonal pancreatic MIN6 beta cells, we used four complementary techniques: immunoelectron microscopy, density gradient fractionation, vesicle immunopurification and fluorescence-activated vesicle isolation. Intravesicular and mitochondrial concentrations of free Ca^{2+} were measured in intact or digitonin-permeabilised MIN6 cells using recombinant, targeted aequorins, and intravesicular pH was measured with the recombinant fluorescent probe pHluorin.
Results SUR1 and Kir6.2 immunoreactivity were concentrated on dense-core vesicles and on vesicles plus the endoplasmic reticulum/Golgi network, respectively, in both islets and MIN6 cells. Reactivity to neither subunit was detected on mitochondria. Glibenclamide, tolbutamide and diazoxide all failed to affect Ca^{2+} uptake into mitochondria, and K_{ATP} channel regulators had no significant effect on intravesicular free Ca^{2+} concentrations or vesicular pH.
Conclusions/Interpretation A significant proportion of Kir6.2 and SUR1 subunits reside on insulin-secretory vesicles and the distal secretory pathway in mouse beta cells but do not influence intravesicular ion homeostasis. We propose that dense-core vesicles may serve instead as sorting stations for the delivery of channels to the plasma membrane.

3.768 Cholesterol depletion facilitates ubiquitylation of NPC1 and its association with SKD1/Vps4
Ohsaki, Y. et al
*J. Cell Sci., **119**, 2643-2653 (2006)*

Niemann-Pick disease type C (NPC) is an inherited lipid storage disorder caused by mutations in *NPC1* or *NPC2*. NPC1 is a polytopic glycoprotein that contains a sterol-sensing domain, whereas NPC2 is a soluble protein that contains an MD-2-like lipid-recognition domain. In the current study, we addressed the hypothesis that ubiquitylation of NPC1 might be regulated by cholesterol. We found that depletion of cellular cholesterol facilitated ubiquitylation of NPC1 expressed in COS cells. A loss-of-function mutant, NPC1(P691S), which contains an amino acid substitution in the sterol-sensing domain, failed to respond to cholesterol depletion. Another mutant, NPC1(δLLNF), which lacks the endosomal-targeting motif, also failed to respond. SKD1(E235Q), a dominant-negative mutant of SKD1/Vps4 that inhibits disassembly of the endosomal sorting complex required for transport (ESCRT), caused an accumulation of ubiquitylated NPC1. SKD1(E235Q) associated with NPC1 on the endosomal membrane, whereas wild-type SKD1 associated with NPC1 only when cells were depleted of cholesterol. Similarly, in control human skin fibroblasts, cholesterol depletion facilitated ubiquitylation of endogenous NPC1. In patient cells that lack NPC2 function, NPC1 was ubiquitylated regardless of cellular cholesterol levels, suggesting that NPC2 is required to prevent NPC1 ubiquitylation under cholesterol-rich conditions. These results suggest that ubiquitylation of NPC1 and its association with the ESCRT complex are controlled by endosomal cholesterol levels utilizing a mechanism that involves NPC2.

3.769 A rat model of human FENIB (familial encephalopathy with neuroserpin inclusion bodies)
Takano, K. et al
*Biochim. Biophys. Res. Comm, **346(3)**, 1040-1047 (2006)*

FENIB (familial encephalopathy with neuroserpin inclusion bodies) is caused by intracellular accumulation/polymerization of mutant neuroserpins in the endoplasmic reticulum (ER). Transgenic rats overexpressing megsin (Tg meg), a newly identified serine protease inhibitor (serpin), demonstrated intraneuronal periodic–acid Schiff (PAS)-positive inclusions distributed throughout deeper layers of cerebral cortex, CA1 of the hippocampus, and substantia nigra. Hippocampal extracts from Tg meg rats showed increased expression of ER stress proteins, and activation of caspases-12 and -3, associated with decreased neuronal density. Enhanced ER stress was also observed in dopaminergic neurons in the substantia nigra, in parallel with decreased neuronal viability and motor coordination. In each case, PAS-

positive inclusions were also positive for megsin. These data suggest that overexpression of megsin results in ER stress, eventuating in the formation of PAS-positive inclusions. Tg meg rats provide a novel model of FENIB, where accumulation of serpins in the ER induces selective dysfunction/loss of specific neuronal populations.

3.770 Retrovirus infection strongly enhances scrapie infectivity release in cell culture
Leblanc, P. et al
*EMBO J., **25**, 2674-2685 (2006)*

Prion diseases are neurodegenerative disorders associated in most cases with the accumulation in the central nervous system of PrP^{Sc} (conformationally altered isoform of cellular prion protein (PrP^{C}); Sc for scrapie), a partially protease-resistant isoform of the PrP^{C}. PrP^{Sc} is thought to be the causative agent of transmissible spongiform encephalopathies. The mechanisms involved in the intercellular transfer of PrP^{Sc} are still enigmatic. Recently, small cellular vesicles of endosomal origin called exosomes have been proposed to contribute to the spread of prions in cell culture models. Retroviruses such as murine leukemia virus (MuLV) or human immunodeficiency virus type 1 (HIV-1) have been shown to assemble and bud into detergent-resistant microdomains and into intracellular compartments such as late endosomes/multivesicular bodies. Here we report that moloney murine leukemia virus (MoMuLV) infection strongly enhances the release of scrapie infectivity in the supernatant of coinfected cells. Under these conditions, we found that PrP^{C}, PrP^{Sc} and scrapie infectivity are recruited by both MuLV virions and exosomes. We propose that retroviruses can be important cofactors involved in the spread of the pathological prion agent.

3.771 Impairment of mitochondrial anti-oxidant defence in SOD1-related motor neuron injury and amelioration by ebselen
Wood-Allum, C.A. et al
*Brain, **129**, 1693-1709 (2006)*

There is now compelling evidence of mitochondrial dysfunction in motor neuron disease (MND), but the molecular basis of these abnormalities is unknown. It is also unclear whether the observed mitochondrial dysfunction plays a central role in disease pathogenesis, and if so, whether its amelioration might present therapeutic opportunities. We adopted a candidate generation approach using proteomics to screen for changes in mitochondrial protein expression in a well-validated cell-culture model of superoxide dismutase 1 (SOD1) related familial MND (fMND). Changed proteins were identified by matrix-assisted laser desorption/ionization time-of-flight (MALDI–TOF) mass spectroscopy. Protein candidates included apoptotic regulators, anti-oxidants and components of the electron transport chain. Confirmatory Western blotting was performed, and validated protein expression changes were further investigated. Peroxiredoxin 3 (Prx3), a mitochondrial thioredoxin-dependent hydroperoxidase, is downregulated in the presence of mutant SOD1 in both our cell-culture model and in the spinal cord mitochondria of mutant SOD1 transgenic mice. We confirm the expression of Prx3 within the mitochondria of spinal motor neurons in mouse and humans by immunohistochemistry. Using quantitative real-time PCR (Q-PCR), we show that Prx3 is also downregulated in spinal motor neurons from patients with both sporadic (sMND) and SOD1-related fMND. In a disease characterized by oxidative stress, this represents a potentially important deficit in mitochondrial anti-oxidant defence. Recent evidence suggests that oxidative stress from aberrant copper chemistry may not play a major part in the pathogenesis of SOD1-related fMND. From the results of this study we propose disruption of mitochondrial anti-oxidant defence as an alternative mechanism whereby mutant SOD1 may generate oxidative stress within motor neurons. We further demonstrate that ebselen, an anti-oxidant drug already safely used in human studies and that acts as a Prx mimic, is able to ameliorate the toxicity of mutant SOD1 in our cell-culture model. We conclude by showing that ebselen is capable of inducing transcription of the anti-oxidant response element (ARE) and postulate that ebselen may act both by the transcriptional upregulation of anti-oxidant proteins, and directly as an anti-oxidant in its own right.

3.772 Melanosomal sequestration of cytotoxic drugs contributes to the intractability of malignant melanomas
Chen, K.G. et al
*PNAS, **103(26)**, 9903-9907 (2006)*

Multidrug resistance mechanisms underlying the intractability of malignant melanomas remain largely unknown. In this study, we demonstrate that the development of multidrug resistance in melanomas

involves subcellular sequestration of intracellular cytotoxic drugs such as *cis*-diaminedichloroplatinum II (cisplatin; CDDP). CDDP is initially sequestered in subcellular organelles such as melanosomes, which significantly reduces its nuclear localization when compared with nonmelanoma/KB-3-1 epidermoid carcinoma cells. The melanosomal accumulation of CDDP remarkably modulates melanogenesis through a pronounced increase in tyrosinase activity. The altered melanogenesis manifested an ≈8-fold increase in both intracellular pigmentation and extracellular transport of melanosomes containing CDDP. Thus, our experiments provide evidence that melanosomes contribute to the refractory properties of melanoma cells by sequestering cytotoxic drugs and increasing melanosome-mediated drug export. Preventing melanosomal sequestration of cytotoxic drugs by inhibiting the functions of melanosomes may have great potential as an approach to improving the chemosensitivity of melanoma cells.

3.773 A Novel Mechanism of Interaction between α-Synuclein and Biological Membranes
Kim, Y.S., Laurine, E., Woods, W. and Lee, S-J.
J. Mol. Biol., ***360(2)***, *386-397 (2006)*

Conformational abnormalities and aggregation of α-synuclein (α-syn) have been linked to the pathogenesis of Parkinson's (PD) and related diseases. It has been shown that α-syn can stably bind artificial phospholipid vesicles through α-helix formation in its N-terminal repeat region. However, little is known about the membrane interaction in cells. In the current study, we determined the membrane-binding properties of α-syn to biological membranes by using bi-functional chemical crosslinkers, which allow the detection of transient, but specific, interactions. By utilizing various point mutations and deletions within α-syn, we demonstrated that the membrane interaction of α-syn in cells is also mediated by α-helix formation in the N-terminal repeat region. Moreover, the PD-linked A30P mutation causes reduced membrane binding, which is concordant with the artificial membrane studies. However, contrary to the interaction with artificial membranes, the interaction with biological membranes is rapidly reversible and is not driven by electrostatic attraction. Furthermore, the interaction of α-syn with cellular membranes occurs only in the presence of non-protein and non-lipid cytosolic components, which distinguishes it from the spontaneity of the interaction with artificial membranes. More interestingly, addition of the cytosolic preparation to artificial membranes resulted in the transient, charge-independent binding of α-syn similar to the interaction with biological membranes. These results suggest that in cells, α-syn is engaged in a fundamentally different mode of membrane interaction than the charge-dependent artificial membrane binding, and the mode of interaction is determined by the intrinsic properties of α-syn itself and by the cytoplasmic context.

3.774 Identification of Proteomic Signatures of Exposure to Marine Pollutants in Mussels (Mytilus edulis)
Apraiz, I., Mi, J. and Cristobal, S.
Mol. Cell. Proteomics, ***5(7)***, *1274-1285 (2006)*

Bivalves and especially mussels are very good indicators of marine and estuarine pollution, and so they have been widely used in biomonitoring programs all around the world. However, traditional single parameter biomarkers face the problem of high sensitivity to biotic and abiotic factors. In our study, digestive gland peroxisome-enriched fractions of *Mytilus edulis* (L., 1758) were analyzed by DIGE and MS. We identified several proteomic signatures associated with the exposure to several marine pollutants (diallyl phthalate, PBDE-47, and bisphenol-A). Animals collected from North Atlantic Sea were exposed to the contaminants independently under controlled laboratory conditions. One hundred and eleven spots showed a significant increase or decrease in protein abundance in the two-dimensional electrophoresis maps from the groups exposed to pollutants. We obtained a unique protein expression signature of exposure to each of those chemical compounds. Moreover a set of proteins composed a proteomic signature in common to the three independent exposures. It is remarkable that the principal component analysis of these spots showed a discernible separation between groups, and so did the hierarchical clustering into four classes. The 14 proteins identified by MS participate in α- and ß-oxidation pathways, xenobiotic and amino acid metabolism, cell signaling, oxyradical metabolism, peroxisomal assembly, respiration, and the cytoskeleton. Our results suggest that proteomic signatures could become a valuable tool to monitor the presence of pollutants in field experiments where a mixture of pollutants is often present. Further studies on the identified proteins could provide crucial information to understand possible mechanisms of toxicity of single xenobiotics or mixtures of them in marine ecosystems.

3.775 Outer Membrane Vesicle Production by Escherichia coli Is Independent of Membrane Instability
McBroom, A.J., Johnson, A.P., Vemulapalli, S. and Kuehn, M.J.
J. Bacteriol., ***188(15)***, *5385-5392 (2006)*

It has been long noted that gram-negative bacteria produce outer membrane vesicles, and recent data demonstrate that vesicles released by pathogenic strains can transmit virulence factors to host cells. However, the mechanism of vesicle release has remained undetermined. This genetic study addresses whether these structures are merely a result of membrane instability or are formed by a more directed process. To elucidate the regulatory mechanisms and physiological basis of vesiculation, we conducted a screen in *Escherichia coli* to identify gene disruptions that caused vesicle over- or underproduction. Only a few low-vesiculation mutants and no null mutants were recovered, suggesting that vesiculation may be a fundamental characteristic of gram-negative bacterial growth. Gene disruptions were identified that caused differences in vesicle production ranging from a 5-fold decrease to a 200-fold increase relative to wild-type levels. These disruptions included loci governing outer membrane components and peptidoglycan synthesis as well as the σ^E cell envelope stress response. Mutations causing vesicle overproduction did not result in upregulation of the *ompC* gene encoding a major outer membrane protein. Detergent sensitivity, leakiness, and growth characteristics of the novel vesiculation mutant strains did not correlate with vesiculation levels, demonstrating that vesicle production is not predictive of envelope instability.

3.776 Ribosomal Protein S6 Associates with Alphavirus Nonstructural Protein 2 and Mediates Expression from Alphavirus Messages

Montgomery, S.A., Berglund, P., Beard, C.W. and Johnston, R.E.
J. Virol., ***80(15)***, *7729-7739 (2006)*

Although alphaviruses dramatically alter cellular function within hours of infection, interactions between alphaviruses and specific host cellular proteins are poorly understood. Although the alphavirus nonstructural protein 2 (nsP2) is an essential component of the viral replication complex, it also has critical auxiliary functions that determine the outcome of infection in the host. To gain a better understanding of nsP2 function, we sought to identify cellular proteins with which Venezuelan equine encephalitis virus nsP2 interacted. We demonstrate here that nsP2 associates with ribosomal protein S6 (RpS6) and that nsP2 is present in the ribosome-containing fractions of a polysome gradient, suggesting that nsP2 associates with RpS6 in the context of the whole ribosome. This result was noteworthy, since viral replicase proteins have seldom been described in direct association with components of the ribosome. The association of RpS6 with nsP2 was detected throughout the course of infection, and neither the synthesis of the viral structural proteins nor the presence of the other nonstructural proteins was required for RpS6 interaction with nsP2. nsP1 also was associated with RpS6, but other nonstructural proteins were not. RpS6 phosphorylation was dramatically diminished within hours after infection with alphaviruses. Furthermore, a reduction in the level of RpS6 protein expression led to diminished expression from alphavirus subgenomic messages, whereas no dramatic diminution in cellular translation was observed. Taken together, these data suggest that alphaviruses alter the ribosome during infection and that this alteration may contribute to differential translation of host and viral messages.

3.777 Cytotoxic Necrotizing Factor Type 1 Delivered by Outer Membrane Vesicles of Uropathogenic Escherichia coli Attenuates Polymorphonuclear Leukocyte Antimicrobial Activity and Chemotaxis

Davis, J.M., Carvalho, H.M., Rasmussen, S.B. and O'Brien, A.D.
Infect. Immun., ***74(8)***, *4401-4408 (2006)*

Cytotoxic necrotizing factor type 1 (CNF1), a toxin produced by many strains of uropathogenic *Escherichia coli* (UPEC), constitutively activates small GTPases of the Rho family by deamidating a single amino acid within these target proteins. Such activated GTPases not only stimulate actin polymerization within affected cells but also, as we previously reported, decrease membrane fluidity on mouse polymorphonuclear leukocytes (PMNs). In that same investigation we found that this diminished membrane movement impedes the clustering of the complement receptor CD11b/CD18 on PMNs and, in turn, decreases PMN phagocytic capacity and microbicidal activity on PMNs in direct contact with CNF1-expressing UPEC as well as on those in proximity to wild-type UPEC. The latter observation suggested to us that CNF1 is released from neighboring bacteria, although at the time of initiation of the study described here, no specific mechanism for export of CNF1 from UPEC had been described. Here we present evidence that CNF1 is released from the CNF1-expressing UPEC strain CP9 (serotype O4/H5/K54) in a complex with outer membrane vesicles (OMVs) and that these CNF1-bearing vesicles transfer biologically active CNF1 to PMNs and attenuate phagocyte function. Furthermore, we show that CNF1-bearing vesicles act in a dose-dependent fashion on PMNs to inhibit their chemotactic response to formyl-Met-Leu-Phe, while purified CNF1 does not. We conclude that OMVs provide a means for delivery of CNF1 from a

UPEC strain to PMNs and thus negatively affect the efficacy of the acute inflammatory response to these organisms.

3.778 The Secretory Granule Protein Syncollin Localizes to HL-60 Cells and Neutrophils
Bach, J-P. et al
J. Histochem. Cytochem., ***54(8)***, *877-888 (2006)*

The secretory granule protein syncollin was first identified in the exocrine pancreas where a population of the protein is associated with the luminal surface of the zymogen granule membrane. In this study we provide first morphological and biochemical evidence that, in addition to its pancreatic localization, syncollin is also present in neutrophilic granulocytes of rat and human origin. By immunohistological studies, syncollin was detected in neutrophilic granulocytes of the spleen. Furthermore, syncollin is expressed by the promyelocytic HL-60 cells, where it is stored in azurophilic granules and in a vesicular compartment. These findings were confirmed by fractionation experiments and immunoelectron microscopy. Treatment with a phorbol ester triggered the release of syncollin indicating that in HL-60 cells it is a secretory protein that can be mobilized upon stimulation. A putative role for syncollin in host defense is discussed.

3.779 Cardiac aquaporin expression in humans, rats, and mice
Butler, T.L. et al
Am. J. Physiol. Heart Circ. Physiol., ***291***, *H705-H713 (2006)*

Water accumulation in the heart is important in ischemia-reperfusion injury and operations performed by using cardiopulmonary bypass, with cardiac dysfunction associated with myocardial edema being the principal determinant of clinical outcome. As an initial step in determining the role of aquaporin (AQP) water channels in myocardial edema, we have assessed the myocardial expression of AQPs in humans, rats, and mice. RT-PCR revealed expression of AQP-1, -4, -6, -7, -8, and -11 transcripts in the mouse heart. AQP-1, -6, -7, and -11 mRNAs were found in the rat heart as well as low levels of AQP-4 and -9. Human hearts contained AQP-1, -3, -4, -5, -7, -9, -10, and -11 mRNAs. AQP-1 protein expression was confirmed by Western blot analysis in all three species. AQP-4 protein was detected in the mouse heart but not in the rat or human heart. To determine the potential functional consequences of myocardial AQP expression, water permeability was measured in plasma membrane vesicles from myocardial cells of wild-type versus various AQP knockout mice. Water permeability was reduced by AQP-1 knockout but not by AQP-4 or AQP-8 knockout. With the use of a model of isolated rat heart perfusion, it was found that osmotic and ischemic stresses are not associated with changes in AQP-1 or AQP-4 expression. These studies support a possible functional role of AQP-1 in myocardium but indicate that early adaptations to osmotic and ischemic stress do not involve transcriptional or posttranslational AQP-1 regulation.

3.780 More than colocalizing with polycystin-1, polycystin-L is in the centrosome
Bui-Xuan, E-F. et al
Am. J. Physiol. Renal Physiol., ***291***, *F395-F406 (2006)*

Polycystin-1 and polycystin-2 are involved in autosomal dominant polycystic kidney disease by unknown mechanisms. These two proteins are located in primary cilia where they mediate mechanosensation, suggesting a link between cilia function and renal disease. In this study, we sought to characterize the subcellular localization of polycystin-L, a closely related member of polycystin-2, in epithelial renal cell lines. We have shown that endogenous polycystin-L subcellular distribution is different in proliferative and nonproliferative cultures. Polycystin-L is found mostly in the endoplasmic reticulum in subconfluent cell cultures, while in confluent cells it is redistributed to sites of cell-cell contact and to the primary cilium as is polycystin-1. Subcellular fractionation confirmed a common distribution of polycystin-L and polycystin-1 in the fractions corresponding to those containing the plasma membrane of postconfluent cells. Reciprocal coimmunoprecipitation experiments showed that polycystin-L was associated with polycystin-1 in a common complex in both subconfluent and confluent cell cultures. Interestingly, we also identified a novel site for a polycystin member (polycystin-L) in unciliated cells, the centrosome, which allowed us to reveal an involvement of polycystin-L in cell proliferation.

3.781 Association of Yeast Transporters with Detergent-Resistant Membranes Correlates with Their Cell-Surface Location
Lauwers, E. and Andre, B.
Traffic, ***7(8)***, *1045-1059 (2006)*

Detergent-resistant membrane (DRM) fractions enriched in ergosterol and sphingolipids can be isolated from yeast cells and have been proposed to represent the biochemical equivalents of lipid rafts. Most yeast plasma membrane proteins studied for their detergent solubility have been found in DRMs, except for the Hxt1 and Gap1 permeases. We here compared Gap1 detergent solubility in wild-type and various mutant cells under conditions promoting cell surface accumulation or ubiquitin-dependent down-regulation of the permease. We show that Gap1 present at the plasma membrane is associated with DRMs. This association occurs at the Golgi level. In the absence of sphingolipid neosynthesis, Gap1 fails to accumulate at the plasma membrane and is missorted to the vacuolar lumen. Furthermore, the presence of Gap1 at the plasma membrane correlates perfectly with its association with DRMs, whatever the activity or ubiquitination state of the permease and regardless of whether it has reached the cell surface via normal secretion, after recycling, or upon missorting to the vacuole before rerouting to the plasma membrane. Finally, we show that Hxt1 present at the cell surface is also associated with DRMs. We discuss a model where yeast plasma membrane proteins are systematically associated with sphingolipid/ergosterol-enriched microdomains when located at the cell surface.

3.782 Dynamic Sequestration of the Recycling Compartment by Classical Protein Kinase C
Idkowiak-Baldys, J., Becker, K.P., Kitatani, K. And Hannum, Y.A.
J. Biol. Chem., ***281(31)***, *22321-22331 (2006)*

It has been previously shown that upon sustained stimulation (30-60 min) with phorbol esters, protein kinase C (PKC)α and βII become sequestered in a juxtanuclear region, the pericentrion. The activation of PKC also results in sequestration of transferrin, suggesting a role for PKC in regulating endocytosis and sequestration of recycling components. In this work we characterize the pericentrion as a PKC-dependent subset of the recycling compartment. We demonstrate that upon sustained stimulation of PKC, both protein (CD59, caveolin) and possibly also lipid (Bodipy-GM1) cargo become sequestered in a PKC-dependent manner. This sequestration displayed a strict temperature requirement and was inhibited below 32 °C. Treatment of cells with phorbol myristate acetate for 60 min led to the formation of a distinct membrane structure. PKC sequestration and pericentrion formation were blocked by hypertonic sucrose as well as by potassium depletion (inhibitors of clathrin-dependent endocytosis) but not by nystatin or filipin, which inhibit clathrin-independent pathways. Interestingly, it was also observed that some molecules that internalize through clathrin-independent pathways (CD59, Bodipy-GM1, caveolin) also sequestered to the pericentrion upon sustained PKC activation, suggesting that PKC acted distal to the site of internalization of endocytic cargo. Together these results suggest that PKC regulates sequestration of recycling molecules into this compartment, the pericentrion.

3.783 Pathogenic mutations of presenilins enhance pro-apoptotic activity by reducing mitochondrial Bcl-2
Wang, H-Q. et al
Alzheimer's and Dementia, ***2(3)***, *Supplement 1, Page S494 (2006)*

Background: The mechanism of neuronal loss in Alzheimer's disease (AD) remains unknown, although circumstantial evidence of apoptosis in postmortem brain tissues has supported the hypothesis that an apoptotic mechanism plays a role in the neurodegeneration in AD. Mutations in presenilins 1 and 2 (PS1/2) are responsible for the majority of familial AD. These proteins are localized predominantly in the endoplasmic reticulum (ER) and Golgi apparatus, and form heteromeric protein complexes to participate in several functions. Previous studies have shown that PS1/2 are involved in the regulation of apoptotic cell death, although the molecular basis is still unresolved. **Objective(s):** The aim of this study is to clarify the molecular basis by which PS1/2 regulate apoptosis. We also address a question how presenilin mutations modify the regulatory activity. **Methods:** We performed yeast 2-hybrid screen, co-immunoprecipitation assay, glycerol velocity gradient centrifugation and subcellular fractionation with iodixanol gradient, using HEK293 cells, PS1/2-knockout mouse fibroblasts and I213T-PS1-knockin mouse brains. **Results:** PS1/2 interacted with FKBP38 that is an immunophilin family member residing in the mitochondrial membrane and inhibits apoptosis by targeting and anchoring antiapoptotic Bcl-2 to the mitochondria. PS1/2 and FKBP38 formed macromolecular complexes together with Bcl-2. This complex formation promoted the degradation of FKBP38 and Bcl-2, and sequestered these proteins in the ER/Golgi compartments, thereby inhibiting FKBP38-mediated mitochondrial targeting of Bcl-2. Thus, full-length PS1/2 increased the susceptibility to apoptosis by antagonizing the anti-apoptotic function of FKBP38. In contrast, C-terminal fragments of caspase-processed PS1/2 redistributed Bcl-2 to the mitochondria by abrogating the activity of full-length PS1/2, resulting in a dominant-negative anti-

apoptotic effect. In cultured cells and mutant PS1-knockin mouse brains, familial AD-linked PS1/2 mutants enhanced the pro-apoptotic activity by causing a more efficient reduction in mitochondrial Bcl-2 than wild-type PS1/2. **Conclusions:** We demonstrated that PS1/2 regulate the susceptibility to apoptosis by interacting with FKBP38. These results suggest a novel molecular mechanism for the regulation of mitochondria-mediated apoptosis by competition between PS1/2 and FKBP38 for subcellular targeting of Bcl-2. Furthermore, familial AD-linked mutations in PS1/2 could lower the threshold for activation of mitochondria-mediated apoptosis pathways inneurons of individuals with familial AD.

3.784 Accumulation of sphingolipids increases secretion of the amyloid β-peptide by stabilization of the β-amyloid precursor protein

Hampel, H., Sandhoff, K. and Walter, J.
Alzheimer's and Dementia, 2(3), Supplement 1, Pages S528-S529 (2006)

Alzheimer's disease is associated with extracellular deposits in the brain of amyloid-_-peptides (A_) that are generated by proteolytic processing of the _-amyloid precursor protein (APP). It has been shown that membrane lipids, including cholesterol and sphingolipids affect the subcellular transport of APP in the secretory pathway and its proteolytic processing. Previously, we also showed that the inhibition of glycosphingolipid (GSL) biosynthesis reduces the secretion of APP and A_. Sphingolipids are highly enriched in the plasma membrane of cells. From here they are transported to late endosomal/lysosomal compartments where they are degraded. Inherited defects in degradation of these lipids cause sphingolipid storage disorders (SLSDs) marked by accumulation of GSLs in neurons associated with severe neurodegeneration. There is also a common defect in lipid transport along the endocytic pathway in SLSDs. Since processing of APP by secretases also occurs predominantly in post- Golgi secretory and endocytic compartments, we investigated the effect of accumulation of sphingolipids on transport and processing of APP. We used cultured cells and experimentally increased GSL levels by incubation with bovine brain gangliosides. The proteolytic processing of APP and its derivatives was studied by the detection of full length and soluble APP, APP C-terminal fragments (CTFs) as well as A_ and by pulse-chase experiments. Distribution of APP and its processing products was analyzed by iodixanol density gradient. The accumulation of GSLs markedly increased the secretion of endogenous APP and A_. A strong increase in total APP-CTF levels upon addition of GSLs was also observed. Addition of sphingomyelin showed similar effects. However _-secretase activity was not affected by GSLs in in vitro assays. By biochemical and cell biological experiments, we demonstrate that the increased levels of cellular GSLs altered the distribution and stability of APP-CTFs. Similar results were also obtained in independent genetic cellular models of GSL storage. On the other hand, GSL deficient cells showed decreased levels of APP-CTFs. Together, these data demonstrate that GSLs enhance the secretion of A_ likely by stabilizing APP-CTFs, thereby providing more substrate for _-secretases. Our studies suggest a novel role of GSLs in regulation of APP trafficking and A_ generation along the endocytic pathway.

3.785 YKE4 (YIL023C) Encodes a Bidirectional Zinc Transporter in the Endoplasmic Reticulum of Saccharomyces cerevisiae

Kumanovics, A., Poruk, K.E., Osborn, K.A., Ward, D.M. and Kaplan, J.
*J. Biol. Chem., **281(32)**, 22566-22574 (2006)*

YIL023C encodes a member of the SLC39A, or ZIP, family, which we refer to as yeast KE4 (*YKE4*) after its mouse ortholog. Yke4p was localized to the endoplasmic reticulum (ER) membrane using Yke4p-specific antiserum. *YKE4* is not an essential gene; however, deletion of *YKE4* resulted in a sensitivity to calcofluor white and poor growth at 36 °C on respiratory substrates containing high zinc. Overexpression of transition metal transporters Zrc1p and Cot1p or the mouse orthologue mKe4 in Δ*yke4* suppressed the poor growth at 36 °C on respiratory substrates. We found that the role of Yke4p depends on the zinc status of the cells. In a zinc-adequate environment, Yke4p transports zinc into the secretory pathway, and the deletion of *YKE4* leads to a zinc-suppressible cell wall defect. In high zinc medium, transport of zinc into the secretory pathway through Yke4p is a way to eliminate zinc from the cytosol, and deletion of *YKE4* leads to toxic zinc accumulation in the cytosol. Under low cytosolic zinc conditions, however, Yke4p removes zinc from the secretory pathway, and deletion of *YKE4* partially compensates for the loss of Msc2p, an ER zinc importer, and therefore helps to alleviate ER stress. In our model, Yke4p balances zinc levels between the cytosol and the secretory pathway, whereas the previously described Msc2p-Zrg17p ER zinc importer complex functions mainly in zinc-depleted conditions to ensure a ready supply of zinc essential for ER functions, such as phospholipid biosynthesis and unfolded protein response.

3.786 Release of iron from ferritin requires lysosomal activity
Kidane, T.Z., Sauble, E. and Linder, M.C.
Am. J. Physiol. Cell Physiol., ***291***, *C445-C455 (2006)*

How ferritin-Fe becomes available for cell functions is unknown. Our previous studies with rat hepatoma cells indicated ferritin had to be degraded to release its Fe. In these studies, we investigated whether this occurs in other cell types and whether lysosomes are required. Release of ferritin-Fe was induced with desferoxamine (DFO) in ^{59}Fe-preloaded hepatoma, Caco2, and erythroid K562 cells and measured by rocket immunoelectrophoresis and autoradiography. The half-lives for ferritin-^{59}Fe and protein were parallel (23, 16, and 11 h for the hepatic, Caco2, and K562 cells, respectively). Co-treatment with 180 μM Fe, leupeptin, chymostatin, or chloroquine markedly decreased rates of ferritin-Fe release and ferritin degradation. Lactacystin had no effect except for a small one in erythroid cells. Fractionation of hepatoma cell lysates on **iodixanol** gradients showed rapid depletion of cytosolic ferritin by DFO treatment but no accumulation in lysosomes. We conclude that regardless of cell type, release of Fe from ferritin occurs mainly through lysosomal proteolysis.

3.787 Lipid rafts mediate ultraviolet light-induced Fas aggregation in M624 melanoma cells
Elyassaki, W. and Wu, S.
Photochem. Photobiol., ***82***, *787-792 (2006)*

Ultraviolet light (UV) induces aggregation of Fas-receptor through a Fas-ligand-independent pathway. However, the mechanism of ultraviolet light-induced Fas-receptor aggregation is not known. In this report, we show that lipid rafts mediate ultraviolet light-induced aggregation of Fas. Our data show that UV induces a redistribution of Fas-receptor in a 25-5% Optiprep continuous gradient. The amount of Fas-receptorS is significantly increased in a gradient fraction that contain lipid rafts and is associated with an increase of FADD and caspase-8. Our data also show that the active dimeric form of caspase-8 (p44/p41) is increased in the lipid raft fraction. In addition, our data show that cholesterol, a major component of lipid rafts, is significantly reduced in only the lipid raft fractions after UV-irradiation. However, ceramide, another major lipid raft component, is increased evenly in all gradient fractions after UV-irradiation. These results suggest that UV alters the composition of major lipid raft components, which leads to the recruitment of Fas-receptor and FADD, with subsequent activation of caspase-8. Based on our results, we propose a novel mechanism by which UV induces apoptosis through a membrane lipid raft-mediated signaling pathway.

3.789 Vascular endothelial cadherin controls VEGFR-2 internalization and signaling from intracellular compartments
Lampugnani, M.G., Orsenigo, F., Gagliani, M.C., Tacchetti, C. and Dejana, E.
J. Cell Biol., ***174(4)***, *593-604 (2006)*

Receptor endocytosis is a fundamental step in controlling the magnitude, duration, and nature of cell signaling events. Confluent endothelial cells are contact inhibited in their growth and respond poorly to the proliferative signals of vascular endothelial growth factor (VEGF). In a previous study, we found that the association of vascular endothelial cadherin (VEC) with VEGF receptor (VEGFR) type 2 contributes to density-dependent growth inhibition (Lampugnani, G.M., A. Zanetti, M. Corada, T. Takahashi, G. Balconi, F. Breviario, F. Orsenigo, A. Cattelino, R. Kemler, T.O. Daniel, and E. Dejana. 2003. *J. Cell Biol.* 161:793–804). In the present study, we describe the mechanism through which VEC reduces VEGFR-2 signaling. We found that VEGF induces the clathrin-dependent internalization of VEGFR-2. When VEC is absent or not engaged at junctions, VEGFR-2 is internalized more rapidly and remains in endosomal compartments for a longer time. Internalization does not terminate its signaling; instead, the internalized receptor is phosphorylated, codistributes with active phospholipase C-γ, and activates p44/42 mitogen-activated protein kinase phosphorylation and cell proliferation. Inhibition of VEGFR-2 internalization reestablishes the contact inhibition of cell growth, whereas silencing the junction-associated density-enhanced phosphatase-1/CD148 phosphatase restores VEGFR-2 internalization and signaling. Thus, VEC

limits cell proliferation by retaining VEGFR-2 at the membrane and preventing its internalization into signaling compartments.

3.790 The membrane proximal disulfides of the EGF receptor extracellular domain are required for high affinity binding and signal transduction but do not play a role in the localization of the receptor to lipid rafts
Macdonald, J., Li, Z., Su, W. and Pike, L.J.
*Biochim. Biophys. Acta, **1763(8)**, 870-878 (2006)*

The EGF receptor is a transmembrane receptor tyrosine kinase that is enriched in lipid rafts. Subdomains I, II and III of the extracellular domain of the EGF receptor participate in ligand binding and dimer formation. However, the function of the cysteine-rich subdomain IV has not been elucidated. In this study, we analyzed the role of the membrane-proximal portion of subdomain IV in EGF binding and signal transduction. A double Cys → Ala mutation that breaks the most membrane-proximal disulfide bond (Cys600 to Cys612), ablated high affinity ligand binding and substantially reduced signal transduction. A similar mutation that breaks the overlapping Cys596 to Cys604 disulfide had little effect on receptor function. Mutation of residues within the Cys600 to Cys612 disulfide loop did not alter the ligand binding or signal transducing activities of the receptor. Despite the fact that the C600,612A EGF receptor was significantly impaired functionally, this receptor as well as all of the other receptors with mutations in the region of residues 596 to 612 localized normally to lipid rafts. These data suggest that the disulfide-bonded structure of the membrane-proximal portion of the EGF receptor, rather than its primary sequence, is important for EGF binding and signaling but is not involved in localizing the receptor to lipid rafts.

3.791 RGS Expression Rate-Limits Recovery of Rod Photoresponses
Krispel, C.M. et al
*Neurons, **51(4)**, 409-416 (2006)*

Signaling through G protein-coupled receptors (GPCRs) underlies many cellular processes, yet it is not known which molecules determine the duration of signaling in intact cells. Two candidates are G protein-coupled receptor kinases (GRKs) and Regulators of G protein signaling (RGSs), deactivation enzymes for GPCRs and G proteins, respectively. Here we investigate whether GRK or RGS governs the overall rate of recovery of the light response in mammalian rod photoreceptors, a model system for studying GPCR signaling. We show that overexpression of rhodopsin kinase (GRK1) increases phosphorylation of the GPCR rhodopsin but has no effect on photoresponse recovery. In contrast, overexpression of the photoreceptor RGS complex (RGS9-1·Gβ5L·R9AP) dramatically accelerates response recovery. Our results show that G protein deactivation is normally at least 2.5 times slower than rhodopsin deactivation, resolving a long-standing controversy concerning the mechanism underlying the recovery of rod visual transduction.

3.792 The Use of GFP to Localize Rho GTPases in Living Cells
Michaelson, D. and Philips, M.
*Methods in Enzymol., **406**, 296-315 (2006)*

The green fluorescent protein (GFP) of the jellyfish *Aequorea victoria* has revolutionized the study of protein localization and dynamics. GFP fusions permit analysis of proteins in living cells and offer distinct advantages over conventional immunofluorescence. Among these are lower background, higher resolution, robust dual color colocalization, and avoidance of fixation artifacts. In the case of Ras and Rho family proteins, GFP fusions have allowed breakthroughs in the understanding of how CAAX proteins are targeted to specific cell membranes and how signaling at different membranes can result in different cellular responses. GFP-tagged Rho proteins have also been informative in analyzing the interactions with the cytosolic chaperone, RhoGDI. The major disadvantages of studying GFP fusion proteins is that they are generally overexpressed relative to endogenous proteins, and the GFP tag can, in principle, affect protein function. Fortunately, in the case of Ras and Rho family proteins, a GFP tag at the N terminus seems to have little effect on protein targeting and function. Nevertheless, it is prudent to confirm GFP fusion protein data with the study of the endogenous protein. This chapter describes the tagging of Rho proteins with GFP and the analysis of GFP–Rho protein localization by epifluorescence and confocal microscopy. It further describes methods of analyzing endogenous Rho proteins as confirmation of data acquired using GFP–Rho fusion proteins. These techniques will be useful for anyone studying Rho protein function and are widely applicable to many cell types and signal transduction systems.

3.793 Activation process of the mosquitocidal δ-endotoxin Cry39A produced by Bacillus thuringiensis subsp. aizawai BUN1-14 and binding property to Anopheles stephensi BBMV
Ito, T., Bando, H. and Asano, S-i.
J. Invertebrate Pathol., ***93(1)***, *29-35 (2006)*

Most δ-endotoxins produced by *Bacillus thuringiensis* require proteolytic processing in order to become active. The *in vitro* and *in vivo* activation processes of Cry39A, a δ-endotoxin that is highly toxic to *Anopheles stephensi*, were investigated. Cry39A with a molecular mass of 72 kDa was processed *in vitro* into a 60 kDa fragment by trypsin and gut extract from *A. stephensi* larvae. N-terminal amino acid sequencing of the 60 kDa fragment revealed that trypsin and the protease(s) in the gut extract cleaved Cry39A between Arg^{61} and Gly^{62}. In contrast, 40 and 25 kDa polypeptides were generated *in vivo* by intramolecular cleavage of the 60 kDa fragment in *A. stephensi* larvae. Further, a co-precipitation assay was used to investigate the binding property of the activated Cry39A to *A. stephensi* BBMV. Cry39A bound to *A. stephensi* BBMV specifically and did not compete with the Cry4Aa toxin. This indicated that the binding molecule(s) for Cry39A might differ from those for Cry4A. In addition, Cry39A preferentially bound to the Triton X-100-insoluble membrane fraction.

3.794 Endogenous spartin, mutated in hereditary spastic paraplegia, has a complex subcellular localization suggesting diverse roles in neurons
Robay, D., Patel, H., Simpson, M.A., Brown, N.A. and Crosby, A.H.
Exp. Cell Res., ***312(15)***, *2764-2777 (2006)*

Mutation of spartin (SPG20) underlies a complicated form of hereditary spastic paraplegia, a disorder principally defined by the degeneration of upper motor neurons. Using a polyclonal antibody against spartin to gain insight into the function of the endogenous molecule, we show that the endogenous molecule is present in two main isoforms of 85 kDa and 100 kDa, and 75 kDa and 85 kDa in human and murine, respectively, with restricted subcellular localization. Immunohistochemical studies on human and mouse embryo sections and in vitro cell studies indicate that spartin is likely to possess both nuclear and cytoplasmic functions. The nuclear expression of spartin closely mirrors that of the snRNP (small nuclear ribonucleoprotein) marker α-Sm, a component of the spliceosome. Spartin is also enriched at the centrosome within mitotic structures. Notably we show that spartin protein undergoes dynamic positional changes in differentiating human SH-SY5Y cells. In undifferentiated non-neuronal cells, spartin displays a nuclear and diffuse cytosolic profile, whereas spartin transiently accumulates in the *trans*-Golgi network and subsequently decorates discrete puncta along neurites in terminally differentiated neuroblastic cells. Investigation of these spartin-positive vesicles reveals that a large proportion colocalizes with the synaptic vesicle marker synaptotagmin. Spartin is also enriched in synaptic-like structures and in synaptic vesicle-enriched fraction.

3.795 Cholesterol depletion reduces aggregation of amyloid-beta peptide in hippocampal neurons
Scheider, A., Schulz-Schaeffer, W., Hartmann, T., Schulz, J.B. and Simons, M.
Neurobiology of Disease, ***23***, *573-577 (2006)*

A key event in the pathogenesis of Alzheimer's disease is the conversion of soluble amyloid Aβ-peptide into toxic aggregates. Here, we studied the effect of cholesterol depletion on the formation of insoluble Aβ. We found that reduction of neuronal cholesterol by ~25% reduced the neuronal formation of insoluble Aβ without affecting the secretion of soluble Aβ. Moreover, we demonstrate that Aβ-oligomers from Alzheimer's disease brains associate with a detergent-resistant membrane fraction in a cholesterol-dependent manner. These results suggest a key role for cholesterol in aggregation of Aβ.

3.796 Cotranslocational Degradation Protects the Stressed Endoplasmic Reticulum from Protein Overload
Oyadomari, S. et al
Cell, ***126(4)***, *727-739 (2006)*

The ER's capacity to process proteins is limited, and stress caused by accumulation of unfolded and misfolded proteins (ER stress) contributes to human disease. ER stress elicits the unfolded protein response (UPR), whose components attenuate protein synthesis, increase folding capacity, and enhance misfolded protein degradation. Here, we report that $P58^{IPK}$/DNAJC3, a UPR-responsive gene previously implicated in translational control, encodes a cytosolic cochaperone that associates with the ER protein translocation channel Sec61. $P58^{IPK}$ recruits HSP70 chaperones to the cytosolic face of Sec61 and can be crosslinked to

proteins entering the ER that are delayed at the translocon. Proteasome-mediated cytosolic degradation of translocating proteins delayed at Sec61 is cochaperone dependent. In $P58^{IPK-/-}$ mice, cells with a high secretory burden are markedly compromised in their ability to cope with ER stress. Thus, $P58^{IPK}$ is a key mediator of cotranslocational ER protein degradation, and this process likely contributes to ER homeostasis in stressed cells.

3.797 Translocation of Endothelial Nitric-Oxide Synthase Involves a Ternary Complex with Caveolin-1 and NOSTRIN
Schilling, K. et al
*Mol. Biol. Cell, **17**, 3870-3880 (2006)*

Recently, we characterized a novel endothelial nitric-oxide synthase (eNOS)-interacting protein, NOSTRIN (for e*NOS-t*rafficking *in*ducer), which decreases eNOS activity upon overexpression and induces translocation of eNOS away from the plasma membrane. Here, we show that NOSTRIN directly binds to caveolin-1, a well-established inhibitor of eNOS. Because this interaction occurs between the N terminus of caveolin (positions 1–61) and the central domain of NOSTRIN (positions 323–434), it allows for independent binding of each of the two proteins to eNOS. Consistently, we were able to demonstrate the existence of a ternary complex of NOSTRIN, eNOS, and caveolin-1 in Chinese hamster ovary (CHO)-eNOS cells. In human umbilical vein endothelial cells (HUVECs), the ternary complex assembles at the plasma membrane upon confluence or thrombin stimulation. In CHO-eNOS cells, NOSTRIN-mediated translocation of eNOS involves caveolin in a process most likely representing caveolar trafficking. Accordingly, trafficking of NOSTRIN/eNOS/caveolin is affected by altering the state of actin filaments or cholesterol levels in the plasma membrane. During caveolar trafficking, NOSTRIN functions as an adaptor to recruit mediators such as dynamin-2 essential for membrane fission. We propose that a ternary complex between NOSTRIN, caveolin-1, and eNOS mediates translocation of eNOS, with important implications for the activity and availability of eNOS in the cell.

3.798 An Internal EELD Domain Facilitates Mitochondrial Targeting of Mcl-1 via a Tom70-dependent Pathway
Chou, C-H., Lee, R-S., Yang-Yen, H-F.
*Mol. Biol. Cell, **17**, 3952-3963 (2006)*

Mcl-1 functions at an apical step in many regulatory programs that control cell death. Although the mitochondrion is one major subcellular organelle where Mcl-1 functions, the molecular mechanism by which Mcl-1 is targeted to mitochondria remains unclear. Here, we demonstrate that Mcl-1 is loosely associated with the outer membrane of mitochondria. Furthermore, we demonstrate that Mcl-1 interacts with the mitochondrial import receptor Tom70, and such interaction requires an internal domain of Mcl-1 that contains an EELD motif. A Tom70 antibody that blocks Mcl-1–Tom70 interaction blocks mitochondrial import of Mcl-1 in vitro. Furthermore, Mcl-1 is significantly less targeted to mitochondria in Tom70 knockdown than in the control cells. Similar targeting preference is also observed for the DM mutant of Mcl-1 whose mutation at the EELD motif markedly attenuates its Tom70 binding activity. Together, our results indicate that the internal EELD domain facilitates mitochondrial targeting of Mcl-1 via a Tom70-dependent pathway.

3.799 Cumulative Mutations Affecting Sterol Biosynthesis in the Yeast Saccharomyces cerevisiae Result in Synthetic Lethality That Is Suppressed by Alterations in Sphingolipid Profiles
Valachovic, M. et al
*Genetics, **173**, 1893-1908 (2006)*

UPC2 and *ECM22* belong to a Zn(2)–Cys(6) family of fungal transcription factors and have been implicated in the regulation of sterol synthesis in *Saccharomyces cerevisiae* and *Candida albicans*. Previous reports suggest that double deletion of these genes in *S. cerevisiae* is lethal depending on the genetic background of the strain. In this investigation we demonstrate that lethality of *upc2*Δ *ecm22*Δ in the S288c genetic background is attributable to a mutation in the *HAP1* transcription factor. In addition we demonstrate that strains containing *upc2*Δ *ecm22*Δ are also inviable when carrying deletions of *ERG6* and *ERG28* but not when carrying deletions of *ERG3*, *ERG4*, or *ERG5*. It has previously been demonstrated that *UPC2* and *ECM22* regulate *S. cerevisiae ERG2* and *ERG3* and that the *erg2*Δ *upc2*Δ *ecm22*Δ triple mutant is also synthetically lethal. We used transposon mutagenesis to isolate viable suppressors of *hap1*Δ, *erg2*Δ, *erg6*Δ, and *erg28*Δ in the *upc2*Δ *ecm22*Δ genetic background. Mutations in two genes (*YND1* and *GDA1*) encoding apyrases were found to suppress the synthetic lethality of three of these triple mutants

but not *erg2*Δ *upc2*Δ *ecm22*Δ. We show that deletion of *YND1*, like deletion of *GDA1*, alters the sphingolipid profiles, suggesting that changes in sphingolipids compensate for lethality produced by changes in sterol composition and abundance.

3.800 Membrane Association of the Cycling Peroxisome Import Receptor Pex5p
Kerssen, D. et al
J. Biol. Chem., ***281(37)***, *27003-27015 (2006)*

Peroxisomal proteins carrying a peroxisome targeting signal type 1 (PTS1) are recognized in the cytosol by the cycling import receptor Pex5p. The receptor-cargo complex docks at the peroxisomal membrane where it associates with multimeric protein complexes, referred to as the docking and RING finger complexes. Here we have identified regions within the *Saccharomyces cerevisiae* Pex5p sequence that interconnect the receptor-cargo complex with the docking complex. Site-directed mutagenesis of the conserved tryptophan residue within a reverse W*XXX*F motif abolished two-hybrid binding with the N-terminal half of Pex14p. In combination with an additional mutation introduced into the Pex13p-binding site, we generated a Pex5p mutant defective in a stable association not only with the docking complex but also with the RING finger peroxins at the membrane. Surprisingly, PTS1 proteins are still imported into peroxisomes in these mutant cells. Because these mutations had no significant effect on the membrane binding properties of Pex5p, we examined yeast and human Pex5p for intrinsic lipid binding activity. *In vitro* analyses demonstrated that both proteins have the potential to insert spontaneously into phospholipid membranes. Altogether, these data strongly suggest that a translocation-competent state of the PTS1 receptor enters the membrane via protein-lipid interactions before it tightly associates with other peroxins.

3.801 Palmitoylation Plays a Role in Targeting Vac8p to Specific Membrane Subdomains
Peng, Y., Tang, F. and Weisman, L.S.
Traffic, ***7***, *1378-1387 (2006)*

Vac8p is a multifunctional yeast protein involved in several distinct vacuolar events including vacuole inheritance, vacuole homotypic fusion, nucleus–vacuole junction formation and the cytoplasm to vacuole protein targeting pathway. Vac8p associates with the vacuole membrane via myristoylation and palmitoylation. Vac8p has three putative palmitoylation sites, at Cys 4, 5 and 7. Here, we show that each of these cysteines may serve as a palmitoylation site. Palmitoylation at Cys 7 alone provides partial function of Vac8p, whereas palmitoylation at either Cys 4 or Cys 5 alone is sufficient for Vac8p function. In the former mutant, there is a severe defect in the localization of Vac8p to the vacuole membrane, while in the latter mutants, there is a partial defect in the localization of Vac8p. In addition, our studies provide evidence that palmitoylation targets Vac8p to specific membrane subdomains.

3.802 Invasion of Host Cells by JC Virus Identifies a Novel Role for Caveolae in Endosomal Sorting of Noncaveolar Ligands
Querbes, W., O'Hara, B.A., Williams, G. and Arwood, W.J.
J. Virol., ***80(19)***, *9402-9413 (2006)*

Invasion of glial cells by the human polyomavirus, JC virus (JCV), leads to a rapidly progressing and uniformly fatal demyelinating disease known as progressive multifocal leukoencephalopathy. The endocytic trafficking steps used by JCV to invade cells and initiate infection are not known. We demonstrated that JCV infection was inhibited by dominant defective and constitutively active Rab5-GTPase mutants that acted at distinct steps in endosomal sorting. We also found that labeled JCV colocalized with labeled cholera toxin B and with caveolin-1 (cav-1) on early endosomes following internalization by clathrin-dependent endocytosis. JCV entry and infection were both inhibited by dominant defective mutants of eps15 and Rab5-GTPase. Expression of a dominant-negative scaffolding mutant of cav-1 did not inhibit entry or infection by JCV. A single-cell knockdown experiment using cav-1 shRNA did not inhibit JCV entry but interfered with a downstream trafficking event important for infection. These data show that JCV enters cells by clathrin-dependent endocytosis, is transported immediately to early endosomes, and is then sorted to a caveolin-1-positive endosomal compartment. This latter step is dependent on Rab5-GTPase, cholesterol, caveolin-1, and pH. This is the first example of a ligand that enters cells by clathrin-dependent endocytosis and is then sorted from early endosomes to caveosomes, indicating that caveolae-derived vesicles play a more important role than previously realized in sorting cargo from early endosomes.

3.803 Reconstitution of Herpes Simplex Virus Type 1 Nuclear Capsid Egress In Vitro
Remillard-Labrosse, G., Guay, G. and Lippe, R.
J. Virol., ***80(19)***, *9741-9753 (2006)*

Newly assembled herpesvirus capsids travel from the nucleus to the plasma membrane by a mechanism that is poorly understood. Furthermore, the contribution of cellular proteins to this egress has yet to be clarified. To address these issues, an in vitro nuclear egress assay that reproduces the exit of herpes simplex virus type 1 (HSV-1) capsids from nuclei isolated from infected cells was established. As expected, the assay has all the hallmarks of intracellular transport assays, namely, a dependence on time, energy, and temperature. Surprisingly, it is also dependent on cytosol and was slightly enhanced by infected cytosol, suggesting an implication of both host and viral proteins in the process. The capsids escaped these nuclei by budding through the inner nuclear membrane, accumulated as enveloped capsids between the two nuclear membranes, and were released in cytosol exclusively as naked capsids, exactly as in intact cells. This is most consistent with the view that the virus escapes by crossing the two nuclear membranes rather than through nuclear pores. Unexpectedly, nuclei isolated at the nonpermissive temperature from cells infected with a U_L26 thermosensitive protease mutant (V701) supported capsid egress. Although electron microscopy, biochemical, and PCR analyses hinted at a likely reconstitution of capsid maturation, DNA encapsidation could not be confirmed by a traditional SQ test. This assay should prove very useful for identification of the molecular players involved in HSV-1 nuclear egress.

3.804 Characterization of erasin (UBXD2): a new ER protein that promotes ER-associated protein degradation
Liang, J. et al
J. Cell Sci., ***119***, *4011-4024 (2006)*

Ubiquitin regulator-X (UBX) is a discrete protein domain that binds p97/valosin-containing protein (VCP), a molecular chaperone involved in diverse cell processes, including endoplasmic-reticulum-associated protein degradation (ERAD). Here we characterize a human UBX-containing protein, UBXD2, that is highly conserved in mammals, which we have renamed erasin. Biochemical fractionation, immunofluorescence and electron microscopy, and protease protection experiments suggest that erasin is an integral membrane protein of the endoplasmic reticulum and nuclear envelope with both its N- and C-termini facing the cytoplasm or nucleoplasm. Localization of GFP-tagged deletion derivatives of erasin in HeLa cells revealed that a single 21-amino-acid sequence located near the C-terminus is necessary and sufficient for localization of erasin to the endoplasmic reticulum. Immunoprecipitation and GST-pulldown experiments confirmed that erasin binds p97/VCP via its UBX domain. Additional immunoprecipitation assays indicated that erasin exists in a complex with other p97/VCP-associated factors involved in ERAD. Overexpression of erasin enhanced the degradation of the ERAD substrate CD3δ, whereas siRNA-mediated reduction of erasin expression almost completely blocked ERAD. Erasin protein levels were increased by endoplasmic reticulum stress. Immunohistochemical staining of brain tissue from patients with Alzheimer's disease and control subjects revealed that erasin accumulates preferentially in neurons undergoing neurofibrillary degeneration in Alzheimer's disease. These results suggest that erasin may be involved in ERAD and in Alzheimer's disease.

3.805 Characterization of Proline-Serine-Rich Carboxyl Terminus in Human Sulfotransferase 2B1b: Immunogenicity, Subcellular Localization, Kinetic Properties, and Phosphorylation
He, D. and Falany, C.N.
Drug. Metab. Dispos., ***34(10)***, *1749-1755 (2006)*

The human sulfotransferase (*SULT*) *2B1* gene is a member of the *SULT2* gene family and encodes two isoforms, SULT2B1a and SULT2B1b. Although messages for both *SULT2B1a* and SULT2B1b are detectable in human tissues, only SULT2B1b has been identified immunologically. Compared with other human SULTs, SULT2B1b has an extension at the proline- and serine-rich carboxyl (PSC) end of about 53 amino acids. The structure and function of this unique PSC extension were investigated. Constructs of full-length SULT2B1b as well as truncated SULT2B1b without the PSC extension were expressed in *Escherichia coli*. Removal of the PSC extension significantly decreased the thermostability of the expressed enzyme as well as decreasing the rate of dehydroepiandrosterone sulfation. Rabbit polyclonal antibodies were raised against both the full-length and truncated SULT2B1b proteins. Immunoblot analysis showed that antibodies raised to full-length SULT2B1b immunoreact only with full-length SULT2B1b, whereas antibodies raised to truncated SULT2B1b react with both full-length and truncated SULT2B1b. Unlike full-length SULT2B1b, truncated SULT2B1b was incapable of translocation to nuclei in transfected

human BeWo choriocarcinoma cells. Phosphorylated serines were detected in the PSC extension of full-length SULT2B1b expressed in BeWo cells but not in truncated SULT2B1b. At least one phosphorylated serine was detected in expressed SULT2B1b via two-dimensional gel electrophoresis, immunoblot analysis, and mass spectroscopic analysis. Bacterially expressed full-length SULT2B1b but not truncated SULT2B1b was phosphorylated by casein kinase or Cdc2 protein kinase in vitro. This study suggests that the PSC extension of SULT2B1b is an important site in the immunogenicity, nuclear translocation, kinetic activity, and thermostability of this SULT isoform.

3.806 The Cannabinoid CB1 Receptor Antagonist Rimonabant (SR141716) Inhibits Human Breast Cancer Cell Proliferation through a Lipid Raft-Mediated Mechanism
Sarnataro, D. Et al
*Mol. Pharmacol., **70(4)**, 1298-1306 (2006)*

The endocannabinoid system has been shown to modulate key cell-signaling pathways involved in cancer cell growth. In this study, we show that cannabinoid receptor type 1 (CB1) antagonist Rimonabant (SR141716) inhibited human breast cancer cell proliferation, being more effective in highly invasive metastatic MDA-MB-231 cells than in less-invasive T47D and MCF-7 cells. The SR141716 antiproliferative effect was not accompanied by apoptosis or necrosis and was characterized by a G_1/S-phase cell cycle arrest, decreased expression of cyclin D and E, and increased levels of cyclin-dependent kinase inhibitor $p27^{KIP1}$. We have also shown that SR141716 exerted a significant antiproliferative action, in vivo, by reducing the volume of xenograft tumors induced by MDA-MB-231 injection in mice. On the other hand, at the concentration range in which we observed the antiproliferative effect in tumor cells, we did not observe evidence of any genotoxic effect on normal cells. Our data also indicate that the SR141716 antiproliferative effect requires lipid raft/caveolae integrity to occur. Indeed, we found that CB1 receptor (CB1R) is completely displaced from lipid rafts in SR141716-treated MDA-MB-231 cells, and cholesterol depletion by methyl-β-cyclodextrin strongly prevented SR141716-mediated antiproliferative effect. Taken together, our results suggest that SR141716 inhibits human breast cancer cell growth via a CB1R lipid raft/caveolae-mediated mechanism.

3.807 Rab14 is part of the early endosomal clathrin-coated TGN microdomain
Proikas-Cezanne, T., Gaugel, A., Frickey, T. and Nordheim, A.
*FEBS Lett., **580**, 5241-5246 (2006)*

Rab14 localizes to the Golgi/TGN and to early endosomes, but its biological function remains unclear. By structural modeling, we identified Rab14-specific residues and established a close relationship between the Rab2/Rab4/Rab14, Rab11/25 and Rab39 sub-groups within the Rab protein family. By quantitative confocal microscopy and by density centrifugation we show that Rab14 is part of the early endosomal AP-1 microdomain. Overexpression of a dominant-negative Rab14 GTP-binding mutant that solely localizes to the Golgi donor compartment accelerated EGF degradation. We suggest that the AP-1 microdomain represents the interconnecting compartment in which Rab14 vesicles cycle between early endosomes and the Golgi cisternae.

3.808 Use of analogs and inhibitors to study the functional significance of protein palmitoylation
Resh, M.D.
*Methods, **40**, 191-197 (2006)*

Covalent attachment of palmitate to proteins is a post-translational modification that exerts diverse effects on protein localization and function. The three key technical approaches required for an investigator to determine the role of palmitoylation of your favorite palmitoylated protein (YFPP) are methods to: (1) detect YFPP palmitoylation; (2) alter or inhibit palmitoylation of YFPP; (3) determine the functional significance of altered YFPP palmitoylation. Here, I describe experimental methods to address these three issues. Both radioactive (radiolabeling with [^{3}H]palmitate or ^{125}I-IC16 palmitate) and non-radioactive (chemical labeling and mass spectrometry) methods to detect palmitoylated proteins are presented. Next, techniques to inhibit protein palmitoylation are described. These include site specific mutagenesis, and treatment of cells with inhibitors of protein palmitoylation, including 2-bromopalmitate, cerulenin, and tunicamycin. Alternative methods to replace palmitate with other fatty acids are also presented. Finally, general approaches to determining the effect of altered palmitoylation status on YFPP association with membranes and lipid rafts, as well as signal transduction, are described.

3.809 Different Routes of Bone Morphogenic Protein (BMP) Receptor Endocytosis Influence BMP Signaling
Hartung, A. et al
*Mol. Cell. Biol., **26(20)**, 7791-7805 (2006)*

Endocytosis is important for a variety of functions in eukaryotic cells, including the regulation of signaling cascades via transmembrane receptors. The internalization of bone morphogenetic protein (BMP) receptor type I (BRI) and type II (BRII) and its relation to signaling were largely unexplored. Here, we demonstrate that both receptor types undergo constitutive endocytosis via clathrin-coated pits (CCPs) but that only BRII undergoes also caveola-like internalization. Using several complementary approaches, we could show that (i) BMP-2-mediated Smad1/5 phosphorylation occurs at the plasma membrane in nonraft regions, (ii) continuation of Smad signaling resulting in a transcriptional response requires endocytosis via the clathrin-mediated route, and (iii) BMP signaling leading to alkaline phosphatase induction initiates from receptors that fractionate into cholesterol-enriched, detergent-resistant membranes. Furthermore, we show that BRII interacts with Eps15R, a constitutive component of CCPs, and with caveolin-1, the marker protein of caveolae. Taken together, the localization of BMP receptors in distinct membrane domains is prerequisite to their taking different endocytosis routes with specific impacts on Smad-dependent and Smad-independent signaling cascades.

3.810 Ultrastructural Analysis of ESCRT Proteins Suggests a Role for Endosome-Associated Tubular–Vesicular Membranes in ESCRT Function
Welsch, S. et al
*Traffic, **7**, 1551-1566 (2006)*

The endosomal sorting complex required for transport (ESCRT) is thought to support the formation of intralumenal vesicles of multivesicular bodies (MVBs). The ESCRT is also required for the budding of HIV and has been proposed to be recruited to the HIV-budding site, the plasma membrane of T cells and MVBs in macrophages. Despite increasing data on the function of ESCRT, the ultrastructural localization of its components has not been determined. We therefore localized four proteins of the ESCRT machinery in human T cells and macrophages by quantitative electron microscopy. All the proteins were found throughout the endocytic pathway, including the plasma membrane, with only around 10 and 3% of the total labeling in the cytoplasm and on the MVBs, respectively. The majority of the labeling (45%) was unexpectedly found on tubular–vesicular endosomal membranes rather than on endosomes themselves. The ESCRT labeling was twice as concentrated on early and late endosomes/lysosomes in macrophages compared with that in T cells, where it was twice more abundant at the plasma membrane. The ESCRT proteins were not redistributed on HIV infection, suggesting that the amount of ESCRT proteins located at the budding site suffices for HIV release. These results represent the first systematic ultrastructural localization of ESCRT and provide insights into its role in uninfected and HIV-infected cells.

3.811 Molecular probes for sensing the cholesterol composition of subcellular organelle membranes
Wang, R. et al
*Biochim. Biophys. Acta, **1761**, 1169-1181 82006)*

Neuroendocrine cells contain two types of secretagogue-regulated acidic compartments: secretory granules (SGs) and synaptic-like microvesicles (SLMVs), which can be identified by acidotropic probes such as acridine orange (AO) and DAMP. We investigated the accumulation of these probes in SGs and SLMVs as a function of glucose levels in the culture media using a pancreatic β-cell line MIN6. AO was accumulated in the low-glucose condition, but not in the high-glucose condition. The AO accumulation correlated well with the SLMV dynamics by glucose and DAMP was localized in the SGs. Because SG membranes are reportedly high in cholesterol, we prepared liposomes with increasing cholesterol levels. AO is well incorporated into liposomes having a 20 to 40 mol% cholesterol composition, whereas DAMP was so in those having over 40 mol% cholesterol levels. Indeed, when cholesterol was depleted from MIN6 SG membranes, DAMP incorporation decreased, instead AO was incorporated. In PC12 cells, AO incorporation into SGs was significant but DAMP incorporation was limited. Consistently, the cholesterol composition was found 37 to 39 mol% in the SG membrane of PC12 cells. We suggest that cholesterol-sensing probes, AO and DAMP, are useful tools for investigating cholesterol compositions in acidic organelle membranes.

3.812 Evidence against Calcium as a Mediator of Mitochondrial Dysfunction during Apoptosis Induced by Arachidonic Acid and Other Free Fatty Acids
Maia, R.C., Culver, C.A. and Laster, S.M.
*J. Immunol., **177**, 6398-6404 (2006)*

Apoptosis is often accompanied by activation of phospholipase A_2, causing release of free fatty acids (FFAs), which in turn are thought to contribute to the loss of mitochondrial transmembrane potential ($\Delta\psi_m$). In these experiments, we asked whether calcium plays a role as an intermediate in this process. A total of 14 FFAs were compared for their ability to cause loss of $\Delta\psi_m$ and for their ability to affect levels of intracellular calcium. Among the FFAs, unsaturated FFAs tended to induce apoptosis while saturated FFAs did not. Arachidonic acid (AA) was most damaging, causing loss of $\Delta\psi_m$ and cell death in 8–10 h while linoleic acid, γ-linolenic acid, and docosapentaenoic also strongly induced apoptosis. Effects of the FFAs on levels of intracellular calcium were very different. Many caused strong calcium responses; however, the ability to induce a strong calcium response was not predictive of ability to induce apoptosis, and overall, we did not find a correlation between apoptosis and calcium induction. Also, verapamil and TMB-8 were able to block the calcium response, but these inhibitors did not prevent loss of $\Delta\psi_m$, indicating that the calcium response is not necessary for FFA-induced loss of $\Delta\psi_m$. In contrast, we found that cyclosporine A could inhibit the AA-induced loss of $\Delta\psi_m$ with both whole cells and isolated mitochondria, confirming that the antimitochondrial effects of FFA can stem from direct effects on the mitochondrial permeability transition pore. Finally, we show that the strong apoptosis-inducing activity of AA may stem from its ability to selectively induce its own release.

3.813 ErbB-4 and TNF-α converting enzyme localization to membrane microd
Thiel, K.W. and Carpenter, G.
*Biochem. Biophys. Res. Comm., **350(3)**, 629-633 (2006)*

Sequential proteolytic processing of ErbB-4 occurs in response to ligand addition. Here, we assess the localization of cleavable and non-cleavable ErbB-4 isoforms to membrane microdomains using three methodologies: (1) Triton X-100-insolubility, (2) Brij98-insolubility, and (3) detergent-free density gradient centrifugation. Whereas ErbB-4 translocated to a Triton X-100-insoluble fraction upon treatment of T47D cells with heregulin, it constitutively associated with a Brij98-insoluble fraction and a lipid raft fraction isolated using detergent-free methodology. Comparison of cleavable and non-cleavable isoforms of ErbB-4 revealed that both ErbB-4 isoforms are constitutively localized to either a Triton X-100-soluble or Brij98-insoluble fraction. In contrast, addition of heregulin resulted in translocation of the cleavable isoform to a detergent-free lipid raft. Tumor necrosis factor-α converting enzyme (TACE), the ectodomain secretase for ErbB-4, was present predominantly in its mature active form in most microdomains analyzed. These data suggest the assembly of ErbB-4 ectodomain cleavage apparatus in a membrane microdomain.

3.814 Targeting β2-microglobulin for induction of tumor apoptosis in human hematological malignancies
Yang, J. et al
*Cancer Cell, **10**, 295-307 (2006)*

We discovered that monoclonal antibodies (mAbs) specific to human β_2-microglobulin (β_2M) induce apoptosis in vitro and were therapeutic in mouse models of myeloma and other hematological tumor cells. Cell death occurred rapidly, without the need for exogenous immunological effector mechanisms. The mAbs induced cell death via recruiting MHC class I molecules to lipid rafts and activating Lyn and PLCγ2, leading to activated JNK and inhibited PI3K/Akt and ERK, compromised mitochondrial integrity, and caspase-9-dependent cascade activation. Although the expression of β_2M on normal hematopoietic cells is a potential safety concern, the mAbs were selective to tumor-transformed cells and did not induce apoptosis of normal cells. Therefore, such mAbs offer the potential for a therapeutic approach to hematological malignancies.

3.815 Protein Misfolding Cyclic Amplification for Diagnosis and Prion Propagation Studies
Castilla, J. et al
*Methods in Enzymol., **412**, 3-21 (2006)*

Diverse human disorders are thought to arise from the misfolding and aggregation of an underlying protein. Among them, prion diseases are some of the most intriguing disorders that can be transmitted by an unprecedented infectious agent, termed prion, composed mainly (if not exclusively) of the misfolded prion protein. The hallmark event in the disease is the conversion of the native prion protein into the disease-

associated misfolded protein. We have recently described a novel technology to mimic the prion conversion process *in vitro*. This procedure, named protein misfolding cyclic amplification (PMCA), conceptually analogous to DNA amplification by polymerase chain reaction (PCR), has important applications for research and diagnosis. In this chapter we describe the rational behind PMCA and some of the many potential applications of this novel technology. We also describe in detail the technical and methodological aspects of PMCA, as well as its application in automatic and serial modes that have been developed with a view to improving disease diagnosis.

3.816 Modulation of GalT1 and SialT1 Sub-Golgi Localization by SialT2 Expression Reveals an Organellar Level of Glycolipid Synthesis Control
Uliana, A.S., Crespo, P.M., Martina, J.A., Daniotti, J.L. and Maccioni, H.J.F.
J. Biol. Chem., ***281(43)***, *32852-32860 (2006)*

Ganglioside glycosyltransferases organize as multienzyme complexes that localize in different sub-Golgi compartments. Here we studied whether in CHO-K1 cells lacking CMP-NeuAc: GM3 sialyltransferase (SialT2), the sub-Golgi localization of UDP-Gal:glucosylceramide beta-1,4-galactosyltransferase (GalT1) and CMP-NeuAc:lactosylceramide sialyltransferase (SialT1) complex is affected when SialT2, another member of this complex, is coexpressed. GalT1 and SialT1 sub-Golgi localization was determined by studying the effect of brefeldin A (BFA) and monensin on the synthesis of glycolipids and on the sub-Golgi localization of GalT1(1-52)-CFP (cyan fluorescent protein) and SialT1(1-54)-YFP (yellow fluorescent protein) chimeras by single cell fluorescence microscopy and by isopycnic subfractionation. We found that BFA, and also monensin, impair the synthesis of glycolipids beyond GM3 ganglioside in wild type (WT) cells but beyond GlcCer in SialT2(+) cells. Although BFA redistributed GalT1-CFP and SialT1-YFP to the endoplasmic reticulum in WT cells, a fraction of these chimeras remained associated with a distal Golgi compartment, enriched in trans Golgi network, and recycling endosome markers in SialT2(+) cells. In BFA-treated cells, the percentage of GalT1-CFP and SialT1-YFP associated with Golgi-like membrane fractions separated by isopycnic subfractionation was higher in SialT2(+) cells than in WT cells. These effects were reverted by knocking down the expression of SialT2 with specific siRNA. Results indicate that sub-Golgi localization of glycosyltransferase complexes may change according to the relative levels of the expression of participating enzymes and reveal a capacity of the organelle to adapt the topology of the glycolipid synthesis machinery to functional states of the cell.

3.817 Kinesin-2 mediates physical and functional interactions between polycystin-2 and fibrocystin
Wu, Y. et al
Hum. Mol. Genet., ***15(22)***, *3280-3292 (2006)*

Autosomal dominant polycystic kidney disease (ADPKD) is caused by mutations in *PKD1*, encoding polycystin-1 (PC1), or *PKD2* (polycystin-2, PC2). Autosomal recessive PKD (ARPKD) is caused by mutations in *PKHD1*, encoding fibrocystin/polyductin (FPC). No molecular link between ADPKD and ARPKD has been determined. Here, we demonstrated, by yeast two-hybrid and biochemical assays, that KIF3B, a motor subunit of kinesin-2, associates with PC2 and FPC. Co-immunoprecipitation experiments using Madin-Darby canine kidney (MDCK) and inner medullary collecting duct (IMCD) cells and human kidney revealed that PC2 and KIF3B, FPC and KIF3B and, furthermore, PC2 and FPC are endogenously in the same complex(es), though no direct association between the PC2 and FPC intracellular termini was detected. *In vitro* binding and Far Western blot experiments demonstrated that PC2 and FPC are in the same complex only if KIF3B is present, presumably by forming a PC2–KIF3B–FPC complex. This was supported by our observation that altering KIF3B level in IMCD cells by over-expression or siRNA significantly affected complexing between PC2 and FPC. Immunofluorescence experiments showed that PC2, FPC and KIF3B partially co-localized in primary cilia of over-confluent and perinuclear regions of sub-confluent cells. Furthermore, KIF3B mediated functional modulation of purified PC2 channels by FPC in a planer lipid bilayer electrophysiology system. The FPC C-terminus substantially stimulated PC2 channel activity in the presence of KIF3B, whereas FPC or KIF3B alone had no effect. Taken together, we discovered that kinesin-2 is a linker between PC2 and FPC and mediates the regulation of PC2 channel function by FPC. Our study may be important for elucidating common molecular pathways for PKD of different genotypes.

3.818 Lipid Phosphate Phosphatases 1 and 3 Are Localized in Distinct Lipid Rafts
Kai, M. et al
J. Biochem., ***140***, *677-686 (2006)*

Lipid phosphate phosphatases (LPPs), integral membrane proteins with six transmembrane domains, dephosphorylate a variety of extracellular lipid phosphates. Although LPP3 is already known to bind to Triton X-100–insoluble rafts, we here report that LPP1 is also associated with lipid rafts distinct from those harboring LPP3. We found that LPP1 was Triton X-100–soluble, but CHAPS-insoluble in LNCaP cells endogenously expressing LPP1 and several LPP1 cDNA–transfected cells including NIH3T3 fibroblasts. In addition to the non–ionic detergent insolubility, LPP1 further possessed several properties formulated for raft-localizing proteins as follows: first, the CHAPS-insolubility was resistant to the actin-disrupting drug cytochalasin D; second, the CHAPS-insoluble LPP1 floated in an **Optiprep** density gradient; third, the CHAPS insolubility of LPP1 was lost by cholesterol depletion; and finally, the subcellular distribution pattern of LPP1 exclusively overlapped with that of a raft marker, cholera toxin B subunit. Interestingly, confocal microscopic analysis showed that LPP1 was distributed to membrane compartments distinct from those of LPP3. Analysis using various LPP1/LPP3 chimeras revealed that their first extracellular regions determine the different Triton X-100 solubilities. These results indicate that LPP1 and LPP3 are distributed in distinct lipid rafts that may provide unique microenvironments defining their non-redundant physiological functions.

3.819 **Aquaporin-5 water channel in lipid rafts of rat parotid glands**
Ishikawa, Y., Cho, G., Yuan, Z., Inoue, N. and Nakae, Y.
*Biochim. Biophys. Acta, **1758(8)**, 1053-1060 (2006)*

Aquaporin-5 (AQP5), an apical plasma membrane (APM) water channel in salivary glands, lacrimal glands, and airway epithelium, has an important role in fluid secretion. The activation of M3 muscarinic acetylcholine receptors (mAChRs) or α1-adrenoceptors on the salivary glands induces salivary fluid secretion. AQP5 localizes in lipid rafts and activation of the M3 mAChRs or α1-adrenoceptors induced its translocation together with the lipid rafts to the APM in the interlobular ducts of rat parotid glands. This review focuses on the mechanisms of AQP5 translocation together with lipid rafts to the APM in the interlobular duct cells of parotid glands of normal rats and the impairment of AQP5 translocation in diabetes and senescence.

3.820 **Myelin basic protein-dependent plasma membrane reorganization in the formation of myelin**
Fitzner, D. et al
*EMBO J., **25**, 5037-5048 (2006)*

During vertebrate development, oligodendrocytes wrap their plasma membrane around axons to produce myelin, a specialized membrane highly enriched in galactosylceramide (GalC) and cholesterol. Here, we studied the formation of myelin membrane sheets in a neuron–glia co-culture system. We applied different microscopy techniques to visualize lipid packing and dynamics in the oligodendroglial plasma membrane. We used the fluorescent dye Laurdan to examine the lipid order with two-photon microscopy and observed that neurons induce a dramatic lipid condensation of the oligodendroglial membrane. On a nanoscale resolution, using stimulated emission depletion and fluorescence resonance energy transfer microscopy, we demonstrated a neuronal-dependent clustering of GalC in oligodendrocytes. Most importantly these changes in lipid organization of the oligodendroglial plasma membrane were not observed in shiverer mice that do not express the myelin basic protein. Our data demonstrate that neurons induce the condensation of the myelin-forming bilayer in oligodendrocytes and that MBP is involved in this process of plasma membrane rearrangement. We propose that this mechanism is essential for myelin to perform its insulating function during nerve conduction.

3.821 **Very Long-chain Fatty Acid-containing Lipids rather than Sphingolipids per se Are Required for Raft Association and Stable Surface Transport of Newly Synthesized Plasma Membrane ATPase in Yeast**
Gaigg, B., Toulmay, A. and Scheiter, R.
*J. Biol. Chem., **281(45)**, 34135-34145 (2006)*

The proton-pumping H^+-ATPase, Pma1p, is an abundant and very long lived polytopic protein of the yeast plasma membrane. Pma1p constitutes a major cargo of the secretory pathway and thus serves as a model to study plasma membrane biogenesis. Pma1p associates with detergent-resistant membrane domains (lipid "rafts") already in the ER, and a lack of raft association correlates with mistargeting of the protein to the vacuole, where it is degraded. We are analyzing the role of specific lipids in membrane domain formation and have previously shown that surface transport of Pma1p is independent of newly synthesized sterols but that sphingolipids with C26 very long chain fatty acid are crucial for raft association and surface transport

of Pma1p (Gaigg, B., Timischl, B., Corbino, L., and Schneiter, R. (2005) *J. Biol. Chem.* 280, 22515-22522). We now describe a more detailed analysis of the function that sphingolipids play in this process. Using a yeast strain in which the essential function of sphingolipids is substituted by glycerophospholipids containing C26 very long chain fatty acids, we find that sphingolipids *per se* are dispensable for raft association and surface delivery of Pma1p but that the C26 fatty acid is crucial. We thus conclude that the essential function of sphingolipids for membrane domain formation and stable surface delivery of Pma1p is provided by the C26 fatty acid that forms part of the yeast ceramide.

3.822 Transactivation of Sphingosine 1-Phosphate Receptors Is Essential for Vascular Barrier Regulation: NOVEL ROLE FOR HYALURONAN AND CD44 RECEPTOR FAMILY
Singleton, P.A., Dudek, S.M., Ma, S-F. and Garcia, J.G.N.
J. Biol. Chem., ***281(45)***, *34381-34393 (2006)*

The role for hyaluronan (HA) and CD44 in vascular barrier regulation is unknown. We examined high and low molecular weight HA (HMW-HA, ~1,000 kDa; LMW-HA, ~2.5 kDa) effects on human transendothelial monolayer electrical resistance (TER). HMW-HA increased TER, whereas LMW-HA induced biphasic TER changes ultimately resulting in EC barrier disruption. HMW-HA induced the association of the CD44s isoform with, and AKT-mediated phosphorylation of, the barrier-promoting sphingosine 1-phosphate receptor ($S1P_1$) within caveolin-enriched lipid raft microdomains, whereas LMW-HA induced brief CD44s association with $S1P_1$ followed by sustained association of the CD44v10 isoform with, and Src and ROCK 1/2-mediated phosphorylation of, the barrier-disrupting $S1P_3$ receptor. HA-induced EC cytoskeletal reorganization and TER alterations were abolished by either disruption of lipid raft formation, CD44 blocking antibody or siRNA-mediated reductions in expression of CD44 isoforms. Silencing $S1P_1$, AKT1, or Rac1 blocked the barrier enhancing effects of HA whereas silencing $S1P_3$, Src, ROCK1/2, or RhoA blocked the barrier disruption induced by LMW-HA. In summary, HA regulates EC barrier function through novel differential CD44 isoform interaction with S1P receptors, S1P receptor transactivation, and RhoA/Rac1 signaling to the EC cytoskeleton.

3.823 Acylation of CD44 and Its Association with Lipid Rafts Are Required for Receptor and Hyaluronan Endocytosis
Thankamony, S.P. and Knudson, W.
J. Biol. Chem., ***281(45)***, *34601-34609 (2006)*

CD44 is a cell surface receptor for the extracellular matrix macromolecule hyaluronan. In addition, CD44 mediates the endocytosis of hyaluronan leading to its subsequent degradation within lysosomes. Using model systems of COS-7 and Flp-293 cells, we demonstrate that the association of CD44 with lipid rafts is essential for the endocytosis of hyaluronan but not the extracellular binding. Further, we demonstrate that palmitoylation of CD44 on two highly conserved cysteine residues is essential for the association with lipid rafts as determined by density gradient ultracentrifugation. Mutations of either cysteine residues or pretreatment of cells with the palmitic acid analog 2-bromopalmitate, reduced the [^{3}H]palmitic acid incorporation into CD44 and prevented CD44-lipid rafts association. Preventing CD44 palmitoylation had no effect on the binding of hyaluronan but inhibited hyaluronan internalization. The turnover of the CD44 receptor itself was also affected by blocking its association with lipid rafts. Using cycloheximide to prevent *de novo* protein synthesis, palmitoylation-deficient cysteine mutants underwent slower turnover from cell surface compared with the palmitoylation-intact wild type, as determined by immunofluorescence and Western blotting. These results indicate that palmitoylation of CD44 is a critical driving determinant to CD44 association with lipid rafts and, concomitantly, the rates of hyaluronan endocytosis and CD44 turnover from cell surface.

3.824 Perturbed Interactions of Mutant Proteolipid Protein/DM20 with Cholesterol and Lipid Rafts in Oligodendroglia: Implications for Dysmyelination in Spastic Paraplegia
Krämer-Alber, E-M., Gehrig-Burger, K., Thiele, C., Trotter, J. and Nave, K-A.
J. Neuroscience, ***26(45)***, *11743-11752 (2006)*

Missense mutations in the human *PLP1* gene lead to dysmyelinating diseases with a broad range of clinical severity, ranging from severe Pelizaeus–Merzbacher disease (PMD) to milder spastic paraplegia type 2 (SPG-2). The molecular pathology has been generally attributed to endoplasmic reticulum (ER) retention of misfolded proteolipid protein (PLP) (and its splice isoform DM20) and induction of the unfolded protein response. As opposed to previous studies of heterologous expression systems, we have analyzed PLP/DM20 trafficking in oligodendroglial cells, thereby revealing differences between PMD and SPG-2-

associated PLP/DM20 isoforms. PLP^{A242V} and $DM20^{A242V}$ (*jimpy-msd* in mice), associated with severe PMD-like phenotype *in vivo*, were not only retained in the ER but also interfered with oligodendroglial process formation. In contrast, glial cells expressing SPG-2-associated PLP^{I186T} or $DM20^{I186T}$ (*rumpshaker* in mice) developed processes, and mutant PLP/DM20 reached a late endosomal/lysosomal compartment. Unexpectedly, PLP/DM20 with either substitution exhibited impaired cholesterol binding, and the association with lipid raft microdomains was strongly reduced. Turnover analysis demonstrated that mutant PLP was rapidly degraded in oligodendroglial cells, with half-lives for PLP > PLP^{I186T} > PLP^{A242V}. Protein degradation was specifically sensitive to proteasome inhibition, although PLP/$DM20^{I186T}$ degradation was also affected by inhibition of lysosomal enzymes. We conclude that, in addition to ER retention and unfolded protein response (UPR) induction, impaired cholesterol binding and lipid raft association are characteristic cellular defects of *PLP1*-missense mutations. Mutant protein is rapidly cleared and does not accumulate in oligodendroglial cells. Whereas UPR-induced cell death governs the PMD phenotype of the *msd* mutation, we propose that impaired cholesterol and lipid raft interaction of the *rsh* protein may contribute to the dysmyelination observed in SPG-2.

3.825 Quantitative Proteomics Analysis of Detergent-resistant Membranes from Chemical Synapses: Evidence for Cholesterol as Spatial Organizer of Synaptic Vesicle Cycling
Jia, J-y. et al
*Mol. Cell. Proteomics, **5**, 2060-2071 (2006)*

Synaptic vesicles (SVs) in the central nervous system upon stimulation undergo rapid calcium-triggered exoendocytic cycling within the nerve terminal that at least in part depends on components of the clathrin- and dynamin-dependent endocytosis machinery. How exocytic SV fusion and endocytic retrieval are temporally and spatially coordinated is still an open question. One possibility is that specialized membrane microdomains characterized by their high content in membrane cholesterol may assist in the spatial coordination of synaptic membrane protein recycling. Quantitative proteomics analysis of detergent-resistant membranes (DRMs) isolated from rat brain synapses or cholesterol-depleted control samples by liquid chromatography-tandem mass spectrometry identified a total of 159 proteins. Among these 122 proteins were classified as cholesterol-dependent DRM or DRM-associated proteins, many of which with proven or hypothesized functions in exoendocytic vesicle cycling including clathrin, the clathrin adaptor complex AP-2, and a variety of SV proteins. In agreement with this, SV membrane and endocytic proteins displayed a partial resistance to extraction with cold Triton X-100 in cultured rat hippocampal neurons where they co-localized with labeled cholera toxin B, a marker for cholesterol-enriched DRMs. Moreover SV proteins formed cholesterol-dependent complexes in CHAPS-extracted synaptic membrane lysates. Our combined data suggest that lipid microdomains may act as spatial coordinators for exoendocytic vesicle cycling at synapses.

3.826 Cellular uptake of fatty acids driven by the ER-localized acyl-CoA synthetase FATP4
Milger, K. et al
*J. Cell Sci., **119**, 4678-4688 (2006)*

Long-chain fatty acids are important metabolites for the generation of energy and the biosynthesis of lipids. The molecular mechanism of their cellular uptake has remained controversial. The fatty acid transport protein (FATP) family has been named according to its proposed function in mediating this process at the plasma membrane. Here, we show that FATP4 is in fact localized to the endoplasmic reticulum and not the plasma membrane as reported previously. Quantitative analysis confirms the positive correlation between expression of FATP4 and uptake of fatty acids. However, this is dependent on the enzymatic activity of FATP4, catalyzing the esterification of fatty acids with CoA. Monitoring fatty acid uptake at the single-cell level demonstrates that the ER localization of FATP4 is sufficient to drive transport of fatty acids. Expression of a mitochondrial acyl-CoA synthetase also enhances fatty acid uptake, suggesting a general relevance for this mechanism. Our results imply that cellular uptake of fatty acids can be regulated by intracellular acyl-CoA synthetases. We propose that the enzyme FATP4 drives fatty acid uptake indirectly by esterification. It is not a transporter protein involved in fatty acid translocation at the plasma membrane.

3.827 Identification of a Novel Apical Sorting Motif and Mechanism of Targeting of the M2 Muscarinic Acetylcholine Receptor
Chmelar, R.S. and Nathanson, N.M.
*J. Biol. Chem., **281(46)**, 35381-35396 (2006)*

Previous studies have shown that the M_2 receptor is localized at steady state to the apical domain in Madin-Darby canine kidney (MDCK) epithelial cells. In this study, we identify the molecular determinants governing the localization and the route of apical delivery of the M_2 receptor. First, by confocal analysis of a transiently transfected glycosylation mutant in which the three putative glycosylation sites were mutated, we determined that *N*-glycans are not necessary for the apical targeting of the M_2 receptor. Next, using a chimeric receptor strategy, we found that two independent sequences within the M_2 third intracellular loop can confer apical targeting to the basolaterally targeted M_4 receptor, Val^{270}-Lys^{280} and Lys^{280}-Ser^{350}. Experiments using Triton X-100 extraction followed by **OptiPrep**™ density gradient centrifugation and cholera toxin β-subunit-induced patching demonstrate that apical targeting is not because of association with lipid rafts. ^{35}S-Metabolic labeling experiments with domain-specific surface biotinylation as well as immunocytochemical analysis of the time course of surface appearance of newly transfected confluent MDCK cells expressing FLAG-M_2-GFP demonstrate that the M_2 receptor achieves its apical localization after first appearing on the basolateral domain. Domain-specific application of tannic acid of newly transfected cells indicates that initial basolateral plasma membrane expression is required for subsequent apical localization. This is the first demonstration that a G-protein-coupled receptor achieves its apical localization in MDCK cells via transcytosis.

3.828 The cell biology of HIV-1 and other retroviruses
Freed, E.O. and Mouland, A.J.
*Retrovirology, **3(77)**, 1-10 (2006)*

In recognition of the growing influence of cell biology in retrovirus research, we recently organized a Summer conference sponsored by the American Society for Cell Biology (ASCB) on the Cell Biology of HIV-1 and other Retroviruses (July 20–23, 2006, Emory University, Atlanta, Georgia). The meeting brought together a number of leading investigators interested in the interplay between cell biology and retrovirology with an emphasis on presentation of new and unpublished data. The conference was arranged from early to late events in the virus replication cycle, with sessions on viral fusion, entry, and transmission; post-entry restrictions to retroviral infection; nuclear import and integration; gene expression/regulation of retroviral Gag and genomic RNA; and assembly/release. In this review, we will attempt to touch briefly on some of the highlights of the conference, and will emphasize themes and trends that emerged at the meeting.

3.829 Study of proteins associated with the Eimeria tenella refractile body by a proteomic approach
De Venevelles, P. et al
*Int. J. Parasitol., **36(13)**, 1399-1407 (2006)*

Refractile bodies (RB), whose function is still unknown, are specific structures of Eimeriidae parasites. In order to study their proteome, RB were purified from *Eimeria tenella* sporozoites by a new procedure using a reversible fixation followed by centrifugation. RB proteins were resolved by two-dimensional electrophoresis. Around 76 and 89 spots were detected on RB two-dimensional gels using gradients in the 3–10 and 4–7 range, respectively. RB proteins were located mainly between pH 5 and 7. RB gels were then compared with previously established maps of the entire sporozoite proteome. Proteins appearing in new spots were identified by mass spectrometry. Thirty protein isoforms were located in RB. Added to the already known RB proteins such as Eimepsin and SO7′, the new RB proteins were defined as haloacid dehalogenase, hydrolase, subtilase, lactacte dehydrogenase or ubiquitin family proteins. The RB proteome analysis confirmed the hypothesis that this structure is a reservoir for proteins necessary to invasion but also suggests that RB have energetic and metabolic functions.

3.830 Purification of outer membrane vesicles from Pseudomonas aeruginosa and their activation of an IL-8 response
Baumann, S.J. and Kuehn, M.J.
*Microbes and Infection, **8(9-10)**, 2400-2408 (2006)*

Considerable lung injury results from the inflammatory response to *Pseudomonas aeruginosa* infections in patients with cystic fibrosis (CF). The *P. aeruginosa* laboratory strain PAO1, an environmental isolate, and isolates from CF patients were cultured in vitro and outer membrane vesicles from those cultures were quantitated, purified, and characterized. Vesicles were produced throughout the growth phases of the culture and vesicle yield was strain-independent. Strain-dependent differences in the protein composition of vesicles were quantitated and identified. The aminopeptidase PaAP (PA2939) was highly enriched in vesicles from CF isolates. Vesicles from all strains elicited IL-8 secretion by lung epithelial cells. These

results suggest that *P. aeruginosa* colonizing the CF lung may produce vesicles with a particular composition and that the vesicles could contribute to inflammation.

3.831 Specific and distinct determinants mediate membrane binding and lipid raft incorporation of HIV-1SF2 Nef
Giese, S.I. et al
Virology, ***355(2)****, 175-191 (2006)*

Membrane association is believed to be a prerequisite for the biological activity of the HIV-1 pathogenicity factor Nef. Attachment to cellular membranes as well as incorporation into detergent-insoluble microdomains (lipid rafts) require the N-terminal myristoylation of Nef. However, this modification is not sufficient for sustained membrane association and a specific raft-targeting signal for Nef has not yet been identified. Using live cell confocal microscopy and membrane fractionation analyses, we found that the N-terminal anchor domain (aa 1–61) is necessary and sufficient for efficient membrane binding of Nef from HIV-1_{SF2}. Within this domain, highly conserved lysine and arginine residues significantly contributed to Nef's membrane association and localization. Plasma membrane localization of Nef was also governed by an additional membrane-targeting motif between residues 40 and 61. Importantly, two lysines at positions 4 and 7 were not essential for the overall membrane association but critically contributed to Nef's incorporation into lipid raft domains. Cell surface receptor downmodulation was largely unaffected by mutations of all N-terminal basic residues, while the association of Nef with Pak2 kinase activity and its ability to augment virion infectivity correlated with its lysine-mediated raft incorporation. In contrast, all basic residues were required for efficient HIV-1 replication in primary human T lymphocytes but did not contribute to the incorporation of Nef into HIV-1 virions. Together, these results unravel that Nef's membrane association is governed by a complex pattern of signature motifs that differentially contribute to individual Nef activities. The identification of a critical raft targeting determinant and the functional characterization of a membrane-bound, non-raft-associated Nef variant indicate raft incorporation as a regulatory mechanism that determines the biological activity of distinct subpopulations of Nef in HIV-infected cells.

3.832 Dual regulation of translation initiation and peptide chain elongation during BDNF-induced LTP in vivo: evidence for compartment-specific translation control
Kanhema, T. et al
J. Neurochem., ***99****, 1328-1337 (2006)*

Protein synthesis underlying activity-dependent synaptic plasticity is controlled at the level of mRNA translation. We examined the dynamics and spatial regulation of two key translation factors, eukaryotic initiation factor 4E (eIF4E) and elongation factor-2 (eEF2), during long-term potentiation (LTP) induced by local infusion of brain-derived neurotrophic factor (BDNF) into the dentate gyrus of anesthetized rats. BDNF-induced LTP led to rapid, transient phosphorylation of eIF4E and eEF2, and enhanced expression of eIF4E protein in dentate gyrus homogenates. Infusion of the extracellular signal-regulated kinase (ERK) inhibitor U0126 blocked BDNF-LTP and modulation of the translation factor activity and expression. Quantitative immunohistochemical analysis revealed enhanced staining of phospho-eIF4E and total eIF4E in dentate granule cells. The *in vitro* synaptodendrosome preparation was used to isolate the synaptic effects of BDNF in the dentate gyrus. BDNF treatment of synaptodendrosomes elicited rapid, transient phosphorylation of eIF4E paralleled by enhanced expression of α-calcium/calmodulin-dependent protein kinase II. In contrast, BDNF had no effect on eEF2 phosphorylation state in synaptodendrosomes. The results demonstrate rapid ERK-dependent regulation of the initiation and elongation steps of protein synthesis during BDNF-LTP *in vivo*. Furthermore, the results suggest a compartment-specific regulation in which initiation is selectively enhanced by BDNF at synapses, while both initiation and elongation are modulated at non-synaptic sites.

3.833 The heterogeneity of NaPi protein dynamics and NaPi cotransport activity in renal brush border membranes
Bliane, J.T. et al
FASEB J., ***20****, A59 (2006)*

Alterations in renal proximal tubule brush border membrane (BBM) cholesterol, sphingomyelin, and glycosphingolipid content play an important role in regulating the activity of the sodium-phosphate cotransporter (NaPi). The molecular mechanisms of how alterations in lipid composition may modulate NaPi activity are not known. We have fractionated BBM prepared from rat kidney using detergent-free

density gradient ultracentrifugation (**OptiPrep**). We have found that the NaPi protein preferentially partitions into lipid rafts. To determine the potential consequences of the partitioning of the NaPi transporter in these lipid domains we have i) measured NaPi transport activity and ii) used fluctuation correlation spectroscopy (FCS) methods to determine NaPi diffusion. Partitioning of NaPi protein into lipid rafts results in i) decreased NaPi cotransport activity and ii) decreased diffusion of NaPi protein. Similar results were obtained in BBM isolated from the superficial cortex (SC) versus the juxtamedullary cortex (JMC). The three-fold decrease in NaPi cotransport activity in JMC-BBM is associated with a 3-fold decrease in NaPi protein diffusion. Our results therefore indicate that partitioning of NaPi protein into lipid rafts results in impairment of its activity and diffusion.

3.834 **APPL1 Associates with TrkA and GIPC1 and Is Required for Nerve Growth Factor-Mediated Signal Transduction**
Lin, D.C. et al
Mol. Cell. Biol., ***26(23)***, *8928-8941 (2006)*

The neurotrophin receptor TrkA plays critical roles in the nervous system by recruiting signaling molecules that activate pathways required for the growth and survival of neurons. Here, we report APPL1 as a TrkA-associated protein. APPL1 and TrkA coimmunoprecipitated in sympathetic neurons. We have identified two routes through which this association can occur. APPL1 was isolated as a binding partner for the TrkA-interacting protein GIPC1 from rat brain lysate by mass spectrometry. The PDZ domain of GIPC1 directly engaged the C-terminal sequence of APPL1. This interaction provides a means through which APPL1 may be recruited to TrkA. In addition, the APPL1 PTB domain bound to TrkA, indicating that APPL1 may associate with TrkA independently of GIPC1. Isolation of endosomal fractions by high-resolution centrifugation determined that APPL1, GIPC1, and phosphorylated TrkA are enriched in the same fractions. Reduction of APPL1 or GIPC1 protein levels suppressed nerve growth factor (NGF)-dependent MEK, extracellular signal-regulated kinase, and Akt activation and neurite outgrowth in PC12 cells. Together, these results indicate that GIPC1 and APPL1 play a role in TrkA function and suggest that a population of endosomes bearing a complex of APPL1, GIPC1, and activated TrkA may transmit NGF signals.

3.835 **Molecular Anatomy of a Trafficking Organelle**
Takamori, S. et al
Cell, ***127***, *831-846 (2006)*

Membrane traffic in eukaryotic cells involves transport of vesicles that bud from a donor compartment and fuse with an acceptor compartment. Common principles of budding and fusion have emerged, and many of the proteins involved in these events are now known. However, a detailed picture of an entire trafficking organelle is not yet available. Using synaptic vesicles as a model, we have now determined the protein and lipid composition; measured vesicle size, density, and mass; calculated the average protein and lipid mass per vesicle; and determined the copy number of more than a dozen major constituents. A model has been constructed that integrates all quantitative data and includes structural models of abundant proteins. Synaptic vesicles are dominated by proteins, possess a surprising diversity of trafficking proteins, and, with the exception of the V-ATPase that is present in only one to two copies, contain numerous copies of proteins essential for membrane traffic and neurotransmitter uptake.

3.836 **ATP-binding Cassette Transporter A1 Expression Disrupts Raft Membrane Microdomains through Its ATPase-related Functions**
Landry, Y.D. et al
J. Biol. Chem., ***281(47)***, *36091-36101 (2006)*

ATP-binding cassette transporter A1 (ABCA1) is known to mediate cholesterol efflux to lipid-poor apolipoprotein A-I. In addition, ABCA1 has been shown to influence functions of the plasma membrane, such as endocytosis and phagocytosis. Here, we report that ABCA1 expression results in a significant redistribution of cholesterol and sphingomyelin from rafts to non-rafts. Caveolin, a raft/caveolae marker also redistributes from punctate caveolae-like structures to the general area of the plasma membrane upon ABCA1 expression. Furthermore, we observed significant reduction of Akt activation in ABCA1-expressing cells, consistent with raft disruption. Cholesterol content in the plasma membrane is, however, not altered. Moreover, we provide evidence that a non-functional ABCA1 with mutation in an ATP-binding domain, A937V, fails to redistribute cholesterol, sphingomyelin, or caveolin. A937V also fails to influence Akt activation. Finally, we show that apolipoprotein A-I preferentially associates with non-raft

membranes in ABCA1-expressing cells. Our results thus demonstrate that ABCA1 causes a change in overall lipid packing of the plasma membrane, likely through its ATPase-related functions. Such reorganization by ABCA1 effectively expands the non-raft membrane fractions and, consequentially, pre-conditions cells for cholesterol efflux.

3.837 Localization and in vitro binding studies suggest that the cytoplasmic/nuclear tobacco lectin can interact in situ with high-mannose and complex N-glyc
Lannoo, N. et al
FEBS Lett., ***580(27)***, *6329-6337 (2006)*

The possible in vivo interaction of the *Nicotiana tabacum* agglutinin (Nictaba) with endogenous glycoproteins was corroborated using a combination of confocal/electron microscopy of an EGFP-Nictaba fusion protein expressed in tobacco Bright Yellow-2 (BY-2) cells and biochemical analyses. In vitro binding studies demonstrated that the expressed EGFP-Nictaba possesses carbohydrate-binding activity. Microscopic analyses confirmed the previously reported cytoplasmic/nuclear location of Nictaba in jasmonate-treated tobacco leaves and provided evidence for the involvement of a nuclear localization signal-dependent transport mechanism. In addition, it became evident that the lectin is not uniformly distributed over the nucleus and the cytoplasm of BY-2 cells. Far Western blot analysis of extracts from whole BY-2 cells and purified nuclei revealed that Nictaba interacts in a glycan inhibitable way with numerous proteins including many nuclear proteins. Enzymatic deglycosylation with PNGase F indicated that the observed interaction depends on the presence of *N*-glycans. Glycan array screening, which showed that Nictaba exhibits a strong affinity for high-mannose and complex *N*-glycans, provided a reasonable explanation for this observation. The cytoplasmic/nuclear localization of a plant lectin that has a high affinity for high-mannose and complex *N*-glycans and specifically interacts with conspecific glycoproteins suggests that *N*-glycosylated proteins might be more important in the cytoplasm and nucleus than is currently believed.

3.838 The role of myristoylation in the membrane association of the Lassa virus matrix protein Z
Strecker, T. et al
Virology, J., ***3***, *93 (2006)*
The Z protein is the matrix protein of arenaviruses and has been identified as the main driving force for budding. Both LCMV and Lassa virus Z proteins bud from cells in the absence of other viral proteins as enveloped virus-like particles. Z accumulates near the inner surface of the plasma membrane where budding takes place. Furthermore, biochemical data have shown that Z is strongly membrane associated. The primary sequence of Z lacks a typical transmembrane domain and until now it is not understood by which mechanism Z is able to interact with cellular membranes. In this report, we analyzed the role of N-terminal myristoylation for the membrane binding of Lassa virus Z. We show that disruption of the N-terminal myristoylation signal by substituting the N-terminal glycine with alanine (Z-G2A mutant) resulted in a significant reduction of Z protein association with cellular membranes. Furthermore, removal of the myristoylation site resulted in a relocalization of Z from a punctuate distribution to a more diffuse cellular distribution pattern. Finally, treatment of Lassa virus-infected cells with various myristoylation inhibitors drastically reduced efficient Lassa virus replication. Our data indicate that myristoylation of Z is critical for its binding ability to lipid membranes and thus, for effective virus budding.

3.839 A Membrane-proximal Tetracysteine Motif Contributes to Assembly of CD3$\delta\epsilon$ and CD3$\gamma\epsilon$ Dimers with the T Cell Receptor
Xu, C., Call, M.E. and Wucherpfennig, K.W.
J. Biol. Chem., ***281(48)***, *36977-36984 (2006)*

Assembly of the T cell receptor (TCR) with its dimeric signaling modules, CD3$\delta\epsilon$, CD3$\gamma\epsilon$, and $\zeta\zeta$, is organized by transmembrane (TM) interactions. Each of the three assembly steps requires formation of a three-helix interface involving one particular basic TCR TM residue and two acidic TM residues of the respective signaling dimer. The extracellular domains of CD3$\delta\epsilon$ and CD3$\gamma\epsilon$ contribute to assembly, but TCR interaction sites on CD3 dimers have not been defined. The structures of the extracellular domains of CD3$\delta\epsilon$ and CD3$\gamma\epsilon$ demonstrated parallel β-strands ending at the first cysteine in the C*XX*C*X*E*XXX* motif present in the stalk segment of each CD3 chain. Mutation of the membrane-proximal cysteines impaired assembly of either CD3 dimer with TCR, and little complex was isolated when all four membrane-proximal cysteines were mutated to alanine. These mutations had, however, no discernable effect on CD3$\delta\epsilon$ or CD3$\gamma\epsilon$ dimerization. CD3$\delta\epsilon$ assembled with a TCRα mutant that lacked both immunoglobulin domains, but shortening of the TCRα connecting peptide reduced assembly, consistent with membrane-

proximal TCRα-CD3$\delta\epsilon$ interactions. Chelation of divalent cations did not affect assembly, indicating that coordination of a cation by the tetracysteine motif was not required. The membrane-proximal cysteines were within close proximity but only formed covalent CD3 dimers when one cysteine was mutated. The four cysteines may thus form two intrachain disulfide bonds integral to the secondary structure of CD3 stalk regions. The three-chain interaction theme first established for the TM domains thus extends into the membrane-proximal domains of TCRα-CD3$\delta\epsilon$ and TCRβ-CD3$\gamma\epsilon$.

3.840 Human cytosolic sulfotransferase 2B1: Isoform expression, tissue specificity and subcellular localization

Falany, C.N., He, D., Dumas, N., Frost, A.R. and Falany, J.L.
J. Steroid Biochem. Mol. Biol., ***102(1-5)***, *214-221 (2006)*

Sulfation is an important Phase II conjugation reaction involved in the synthesis and metabolism of steroids in humans. Two different isoforms (2B1a and 2B1b) are encoded by the sulfotransferase (SULT) 2B1 gene utilizing different start sites of transcription resulting in the incorporation of different first exons. SULT2B1a and SULT2B1b are 350 and 365 amino acids in length, respectively, and the last 342 aa are identical. Message for both SULT2B1 isoforms is present in human tissues although SULT2B1b message is generally more abundant. However, to date only SULT2B1b protein has been detected in human tissues or cell lines. SULT2B1b is localized in the cytosol and/or nuclei of human cells. A unique 3′-extension of SULT2B1b is required for nuclear localization in human BeWo placental choriocarcinoma cells. Nuclear localization is stimulated by forskolin treatment in BeWo cells and serine phosphorylation has been identified in the 3′-extension. SULT2B1b is selective for the sulfation of 3β-hydroxysteroids such as dehydroepiandrosterone and pregnenolone, and may also have a role in cholesterol sulfation in human skin. The substrate specificity, nuclear localization, and tissue localization of SULT2B1b suggest a role in regulating the responsiveness of cells to adrenal androgens via their direct inactivation or by preventing their conversion to more potent androgens and estrogens.

3.841 Respiratory Syncytial Virus F Envelope Protein Associates with Lipid Rafts without a Requirement for Other Virus Proteins

Fleming, E.H., Kolokoltsov, A.A., Davey, R.A., Nichols, J.E. and Roberts Jr., N.J.
J. Virol., ***80(24)***, *12160-12170 (2006)*

Like many enveloped viruses, human respiratory syncytial virus (RSV) assembles at and buds from lipid rafts. Translocation of the envelope proteins to these membrane subdomains is essential for production of infectious virus, but the targeting mechanism is poorly understood and it is not known if other virus proteins are required. Here we demonstrate that F protein of RSV intrinsically targets to lipid rafts without a requirement for any other virus protein, including the SH and G envelope proteins. Recombinant virus deficient in SH and G but retaining F protein expression was used to demonstrate that F protein still localized in rafts in both A549 and HEp-2 cells. Expression of a recombinant F gene by use of plasmid vectors demonstrated that F contains its own targeting domain and localized to rafts in the absence of other virus proteins. The domain responsible for translocation was then mapped. Unlike most other virus envelope proteins, F is unusual since the target signal is not contained within the cytoplasmic domain nor did it involve fatty acid modified residues. Furthermore, exchange of the transmembrane domain with that of the vesicular stomatitis virus G protein, a nonraft protein, did not alter F protein raft localization. Taken together, these data suggest that domains present in the extracellular portion of the protein are responsible for lipid raft targeting of the RSV F protein.

3.842 Transition of Galactosyltransferase 1 from Trans-Golgi Cisterna to the Trans-Golgi Network Is Signal Mediated

Schaub, B.E., Berger, B., Berger, E.G. and Rohrer, J.
Mol. Biol. Cell, ***17***, *5153-5162 (2006)*

The Golgi apparatus (GA) is the organelle where complex glycan formation takes place. In addition, it is a major sorting site for proteins destined for various subcellular compartments or for secretion. Here we investigate β1,4-galactosyltransferase 1 (galT) and α2,6-sialyltransferase 1 (siaT), two *trans*-Golgi glycosyltransferases, with respect to their different pathways in monensin-treated cells. Upon addition of monensin galT dissociates from siaT and the GA and accumulates in swollen vesicles derived from the *trans*-Golgi network (TGN), as shown by colocalization with TGN46, a specific TGN marker. We analyzed various chimeric constructs of galT and siaT by confocal fluorescence microscopy and time-lapse videomicroscopy as well as **Optiprep** density gradient fractionation. We show that the first 13 amino acids

of the cytoplasmic tail of galT are necessary for its localization to swollen vesicles induced by monensin. We also show that the monensin sensitivity resulting from the cytoplasmic tail can be conferred to siaT, which leads to the rapid accumulation of the galT–siaT chimera in swollen vesicles upon monensin treatment. On the basis of these data, we suggest that cycling between the *trans*-Golgi *cisterna* and the *trans*-Golgi network of galT is signal mediated.

3.843 PER1 Is Required for GPI-Phospholipase A2 Activity and Involved in Lipid Remodeling of GPI-anchored Proteins

Fujita, M., Umemura, M., Yoko-o, T. and Jigami, Y.
*Mol. Biol. Cell, **17**, 5253-5264 (2006)*

Glycosylphoshatidylinositol (GPI) anchors are remodeled during their transport to the cell surface. Newly synthesized proteins are transferred to a GPI anchor, consisting of diacylglycerol with conventional C16 and C18 fatty acids, whereas the lipid moiety in mature GPI-anchored proteins is exchanged to either diacylglycerol containing a C26:0 fatty acid in the *sn*-2 position or ceramide in *Saccharomyces cerevisiae*. Here, we report on *PER1*, a gene encoding a protein that is required for the GPI remodeling pathway. We found that GPI-anchored proteins could not associate with the detergent-resistant membranes in *per1*Δ cells. In addition, the mutant cells had a defect in the lipid remodeling from normal phosphatidylinositol (PI) to a C26 fatty acid–containing PI in the GPI anchor. In vitro analysis showed that *PER1* is required for the production of lyso-GPI, suggesting that Per1p possesses or regulates the GPI-phospholipase A_2 activity. We also found that human *PERLD1* is a functional homologue of *PER1*. Our results demonstrate for the first time that *PER1* encodes an evolutionary conserved component of the GPI anchor remodeling pathway, highlighting the close connection between the lipid remodeling of GPI and raft association of GPI-anchored proteins..

3.844 Enhanced Amyloidogenic Metabolism of the Amyloid β-Protein Precursor in the X11L-deficient Mouse Brain

Sano, Y. et al
*J. Biol. Chem., **281(49)**, 37853-37860 (2006)*

X11L, a neuronal adaptor protein, associates with the cytoplasmic domain of APP and suppresses APP cellular metabolism. APP is the precursor of Aβ, whose metabolism is strongly implicated in Alzheimer disease pathogenesis. To examine the roles of X11L function in APP metabolism, including the generation of Aβ in the brain, we produced X11L-deficient mutant mice on the C57BL/6 background. The mutant mice did not exhibit histopathological alterations or compensatory changes in the expression of other X11 family proteins, X11 and X11L2. The expression level and distribution of APP in the brain of mutant mice were also identical to those in wild-type mice. However, in the hippocampus, where substantial levels of X11L and APP are expressed, the mutant mice exhibited a significant increase in the level of the C-terminal fragments of APP produced by cleavage with β-secretase but not α-secretase. The levels of Aβ were increased in the hippocampus of aged mutant mice as compared with age-matched controls. These observations clearly indicate that X11L suppresses the amyloidogenic but not amyloidolytic processing of APP in regions of the brain such as the hippocampus, which express significant levels of X11L.

3.845 Studies of Optineurin, a Glaucoma Gene: Golgi Fragmentation and Cell Death from Overexpression of Wild-Type and Mutant Optineurin in Two Ocular Cell Types

Park, B-C., Shen, X., Samaraweera, M. and Yue, B.Y.J.T.
*Am. J: Pathol., **169(6)**, 1976-1989 (2006)*

Optineurin (OPTN) has recently been linked to glaucoma, a major cause of blindness worldwide. Mutations in OPTN such as $Glu^{50}\rightarrow$Lys (E50K) have been reported in patients, particularly those with normal pressure glaucoma. Here, we show that the endogenous OPTN was not secreted in two ocular cell types, human trabecular meshwork and retinal pigment epithelial cells. It localized instead in the cytoplasm in a diffuse pattern without a distinct association with the Golgi apparatus. When overexpressed, however, wild-type OPTN-green fluorescent protein (GFP) formed foci especially around the Golgi, colocalizing partially with the common endocytic pathway marker transferrin receptor in both cell types. Fragmentation of the Golgi was also observed. On nocodazole treatment, the OPTN foci were dispersed into the cytoplasm. Overexpression of mutant $OPTN_{E50K}$-GFP resulted in a greater number ($\boldsymbol{P} < 0.0055$) and size of the foci, compared with the wild type, and the Golgi alteration was potentiated. Cell loss observed in OPTN-expressing cultures was also more pronounced in $OPTN_{E50K}$-GFP compared with that of wild-type OPTN-GFP counterparts ($\boldsymbol{P} < 0.01$). This study highlights a possible role of OPTN in vesicle trafficking

and Golgi integrity. It also provides in-sights into the possible mechanisms why E50K would exhibit a propensity toward the development of glaucoma.

3.846 RalA-exocyst-dependent Recycling Endosome Trafficking Is Required for the Completion of Cytokinesis
Chen, X-W., Inoue, M., Hsu, S. and Saltiel, A.R.
J. Biol. Chem., ***281(50)***, *38609-38616 (2006)*

In eukaryotic cells, recycling endosome-mediated trafficking contributes to the completion of cytokinesis, in a manner under the control of the centrosome. We report that the exocyst complex and its interacting GTPase RalA play a critical role in this polarized trafficking process. RalA resides in the recycling endosome and relocates from the pericentrosomal region to key cytokinetic structures including the cleavage furrow, and later, the abscission site. This event is coupled to the dynamic redistribution of the exocyst proteins. These associate with the centrosome in interphase and concentrate on the central spindle/midbody during cytokinesis. Disruption of RalA-exocyst function leads to cytokinesis failure in late stages, particularly abscission, resembling the cytokinesis defects induced by loss of centrosome function. These data suggest that RalA and the exocyst may regulate vesicle delivery to the centrosome-related abscission site during the terminal stage of cytokinesis, implicating RalA as a critical regulator of cell cycle progression.

3.847 Peroxisomal membrane permeability and solute transfer
Antonenkov, V.D. anfd Hiltunen, J.K.
Biochim. Biophys. Acta, Mol. Cell Res., ***1763*** *(2006)*

The review is dedicated to recent progress in the study of peroxisomal membrane permeability to solutes which has been a matter of debate for more than 40 years. Apparently, the mammalian peroxisomal membrane is freely permeable to small solute molecules owing to the presence of pore-forming channels. However, the membrane forms a permeability barrier for 'bulky' solutes including cofactors (NAD/H, NADP/H, CoA, and acetyl/acyl-CoA esters) and ATP. Therefore, peroxisomes need specific protein transporters to transfer these compounds across the membrane. Recent electrophysiological studies have revealed channel-forming activities in the mammalian peroxisomal membrane. The possible involvement of the channels in the transfer of small metabolites and in the formation of peroxisomal shuttle systems is described.

3.848 Transition of Galactosyltransferase 1 from Trans-Golgi Cisterna to the Trans Golgi Network (and Back) is Signal Mediated
Schaub, B., Berger, B., Berger, E. and Rohrer, J.
Mol. Biol. Cell, ***17*** *(Suppl), abstract 1814 (2006)*

The Golgi apparatus (GA) is the organelle where complex glycan formation takes place. In addition, it is a major sorting site for proteins destined for various sub-cellular compartments or for secretion. Here we investigate β1,4-galactosyltransferase 1 (galT) and α2,6-sialyltransferase 1 (siaT), two *trans*-Golgi glycosyltransferases, with respect to their different pathways in monensin treated cells. Upon addition of monensin galT dissociates from siaT and the GA and accumulates in swollen vesicles derived from the *trans*-Golgi network (TGN), as shown by co-localization with TGN46, a specific TGN marker.
We analyzed various chimeric constructs of galT and siaT by confocal fluorescence microscopy and time lapse video-microscopy as well as Optiprep density gradient fractionation. We show that the first 13 amino acids of the cytoplasmic tail of galT are necessary and sufficient for its localization to swollen vesicles induced by monensin. We also show that the monensin sensitivity resulting from these 13 amino acids can be conferred to siaT, which leads to the rapid accumulation of the galT-siaT chimera in swollen vesicles upon monensin treatment. Based on these data we suggest that cycling between the *trans*-Golgi *cisterna* and the *trans*-Golgi network of galT is signal mediated.

3.849 Characterization of Membrane-associated APC Pools in Motile versus Non-Motile Epithelial Cells
Siemers, K.A., Caro-Gonzales, H.Y., Nelson, W.J. and Barth, A.I.M.
Mol. Biol. Cell, ***17*** *(Suppl.), abstract 299 (2006)*

The adenomatous polyposis coli (APC) protein has an important role in directed cell migration and localizes to the tip of extending membranes in response to growth factor or integrin-mediated signals. Here we used a biochemical approach to analyze the association of APC and its binding partners with

membranes in motile and non-motile epithelial cells. In non-polarized motile Madin Darby Canine kidney (MDCK) epithelial cells, homogenized under conditions that disrupt the microtubule cytoskeleton, the majority of APC and its binding partners Asef and β-catenin were recovered in the membrane fraction whereas tubulin was cytosolic. To further analyze the different cytosolic and membrane-associated APC pool we used a self-forming iodixanol density gradient. APC was enriched in two membrane fractions: a lower density membrane fraction that co-distributes with E-cadherin and β-catenin and a higher density membrane fraction that co-distributes with Asef, IQGAP and Par-3. In polarized non-motile MDCK epithelial cells the majority of APC was enriched in the lower density membrane fraction with E-cadherin. Disruption of cell-cell adhesion causes a shift of APC from this lower density "E-cadherin"-membrane fraction into the higher density "IQGAP/Asef"-membrane fraction. These results indicate that APC complexes that distribute in these higher density fractions may have a role in cell motility.

3.850 Comprehensive Protein Analysis of Naked2-associated Exocytic Vesicles by LC/MS-MS
Cao, Z. et al
*Mol. Biol. Cell, **17**, (Suppl.), abstract 2621 (2006)*

Polarized epithelial cells have developed specialized mechanisms for targeting *trans*Golgi network (TGN)-derived vesicles to the apical or basolateral membrane. We have reported that Naked2, but not Naked1, interacts with Golgi-processed form of TGFα and escorts TGFα-containing exocytic vesicles from the TGN to the basolateral surface of polarized MDCK cells, where the vesicles dock and fuse in a Naked2 myristoylation-dependent manner. In myristoylation-deficient (G2A) Naked2-expressing MDCK cells, Naked2-associated TGFα-containing vesicles are trapped in the cytoplasm and TGFα is unable to reach the plasma membrane. To determine the protein compositions of these Naked2-associated vesicles, we performed a biochemical enrichment followed by flow cytometric purification. Using a 10-40% iodixanol gradient centrifugation, we first isolated G2A Naked2-EGFP-containing vesicle fractions de-enriched in plasma membrane markers as measured by western blotting for Naked2 and markers of subcellular compartments. This pool of vesicles was then subjected to dual flow sorting using GFP and DiD (1,1'-dioctadecyl-3,3,3',3'-tetramethylindodicarbocyanine perchlorate) lipid incorporation to achieve 99.3% purity. Proteomic analysis of this flow-sorted population of vesicles by LC/MS-MS has identified 296 proteins using a criterion of 3 or more peptides per protein present in order to be included in the list. This list includes known trafficking proteins as well as new and previously unrecognized potential trafficking proteins. To date, we have validated colocalization of Annexin I and II in both wild-type and G2A Naked2-associated vesicles. To our knowledge, this represents the first example of a comprehensive protein characterization of a subset of exocytic vesicles.

3.851 Trafficking of Shiga toxin/Shiga-like toxin-1 in human glomerular microvascular endothelial cells and human mesangial cells
Warnier, M. et al
*Kidney Int., **70(12)**, 2085-2091 (2006)*

This study has determined the intracellular transport route of Shiga-like toxin (Stx) and the highly related Shiga toxin in human glomerular microvascular endothelial cells (GMVECs) and mesangial cells. In addition, the effect of tumor necrosis factor-α (TNF-α), which contributes to the pathogenesis of hemolytic-uremic syndrome, was evaluated more profound. Establishing the transport route will provide better understanding of the cytotoxic effect of Stx on renal cells. For our studies, we used receptor-binding B-subunit (StxB), which is identical between Shiga toxin and Stx-1. The transport route of StxB was studied by immunofluorescence microscopy and biochemical assays that allow quantitative analysis of retrograde transport from plasma membrane to Golgi apparatus and endoplasmic reticulum (ER). In both cell types, StxB was detergent-resistant membrane associated and followed the retrograde route. TNF-α upregulated Gb3 expression in mesangial cells and GMVECs, without affecting the efficiency of StxB transport to the ER. In conclusion, our study shows that in human GMVECs and mesangial cells, StxB follows the retrograde route to the Golgi apparatus and the ER. TNF-α treatment increases the amount of cell-associated StxB, but not retrograde transport as such, making it likely that the strong TNF-α-induced sensitization of mesangial cells and GMVECs for the toxic action of Stx is not due to a direct effect on the intracellular trafficking of the toxin.

3.852 Tankyrase recruitment to the lateral membrane in polarized epithelial cells: regulation by cell–cell contact and protein poly(ADP-ribosyl)ation
Yeh, T-Y. et al
*Biochem. J., **399(3)**, 415-425 (2006)*

PARsylation [poly(ADP-ribosyl)ation] of proteins is implicated in the regulation of diverse physiological processes. Tankyrase is a molecular scaffold with this catalytic activity and has been proposed as a regulator of vesicular trafficking on the basis, in part, of its Golgi localization in non-polarized cells. Little is known about tankyrase localization in polarized epithelial cells. Using MDCK (Madin–Darby canine kidney) cells as a model, we found that E-cadherin-mediated intercellular adhesion recruits tankyrase from the cytoplasm to the lateral membrane (including the tight junction), where it stably associates with detergent-insoluble structures. This recruitment is mostly completed within 8 h of calcium-induced formation of cell–cell contact. Conversely, when intercellular adhesion is disrupted by calcium deprivation, tankyrase returns from the lateral membrane to the cytoplasm and becomes more soluble in detergents. The PARsylating activity of tankyrase promotes its dissociation from the lateral membrane as well as its ubiquitination and proteasome-mediated degradation, resulting in an apparent protein half-life of ~2 h. Inhibition of tankyrase autoPARsylation using H_2O_2-induced NAD^+ depletion or PJ34 [*N*-(6-oxo-5,6-dihydrophenanthridin-2-yl)-*N*,*N*-dimethylacetamide hydrochloride] treatment results in tankyrase stabilization and accumulation at the lateral membrane. By contrast, stabilization through proteasome inhibition results in tankyrase accumulation in the cytoplasm. These data suggest that cell–cell contact promotes tankyrase association with the lateral membrane, whereas PARsylating activity promotes translocation to the cytosol, which is followed by ubiquitination and proteasome-mediated degradation. Since the lateral membrane is a sorting station that ensures domain-specific delivery of basolateral membrane proteins, the regulated tankyrase recruitment to this site is consistent with a role in polarized protein targeting in epithelial cells.

3.853 Quantitative proteomic approach to study subcellular localization of membrane proteins
Sadowski, P.G. et al
*Nature Protocols, **1(4)**, 1778-1789 (2006)*

As proteins within cells are spatially organized according to their role, knowledge about protein localization gives insight into protein function. Here, we describe the LOPIT technique (localization of organelle proteins by isotope tagging) developed for the simultaneous and confident determination of the steady-state distribution of hundreds of integral membrane proteins within organelles. The technique uses a partial membrane fractionation strategy in conjunction with quantitative proteomics. Localization of proteins is achieved by measuring their distribution pattern across the density gradient using amine-reactive isotope tagging and comparing these patterns with those of known organelle residents. LOPIT relies on the assumption that proteins belonging to the same organelle will co-fractionate. Multivariate statistical tools are then used to group proteins according to the similarities in their distributions, and hence localization without complete centrifugal separation is achieved. The protocol requires approximately 3 weeks to complete and can be applied in a high-throughput manner to material from many varied sources.

3.854 Physiological Mouse Brain Aβ Levels Are Not Related to the Phosphorylation State of Threonine-668 of Alzheimer's APP
Sano, Y. et al
*PloS, **1**, e51 (2006)*

Background
Amyloid-β peptide species ending at positions 40 and 42 (Aβ40, Aβ42) are generated by the proteolytic processing of the Alzheimer's amyloid precursor protein (APP). Aβ peptides accumulate in the brain early in the course of Alzheimer's disease (AD), especially Aβ42. The cytoplasmic domain of APP regulates intracellular trafficking and metabolism of APP and its carboxyl-terminal fragments (CTFα, CTFβ). The role of protein phosphorylation in general, and that of the phosphorylation state of APP at threonine-668 (Thr^{668}) in particular, has been investigated in detail by several laboratories (including our own). Some investigators have recently proposed that the phosphorylation state of Thr^{668} plays a pivotal role in governing brain Aβ levels, prompting the current study.
Methodology
In order to evaluate whether the phosphorylation state of Thr^{668} controlled brain Aβ levels, we studied the levels and subcellular distributions of holoAPP, sAPPα, sAPPβ, CTFα, CTFβ, Aβ40 and Aβ42 in brains from “knock-in” mice in which a non-phosphorylatable alanyl residue had been substituted at position 668, replacing the threonyl residue present in the wild-type protein.
Conclusions
The levels and subcellular distributions of holoAPP, sAPPα, sAPPβ, CTFα, CTFβ, Aβ40 and Aβ42 in the brains of Thr^{668}Ala mutant mice were identical to those observed in wild-type mice. These results indicate

that, despite speculation to the contrary, the phosphorylation state of APP at Thr^{668} does not play an obvious role in governing the physiological levels of brain Aβ40 or Aβ42 *in vivo*.

3.855 Cellular Prion Protein and Caveolin-1 Interaction in a Neuronal Cell Line Precedes Fyn/Erk 1/2 Signal Transduction
Toni, M. et al
J. Biomed. Biotechnol., ***206***, *1-13 (2006)*

It has been reported that cellular prion protein (PrPc) is enriched in caveolae or caveolae-like domains with caveolin-1 (Cav-1) participating to signal transduction events by Fyn kinase recruitment. By using the Glutathione-S-transferase (GST)-fusion proteins assay, we observed that PrPc strongly interacts in vitro with Cav-1. Thus, we ascertained the PrPc caveolar localization in a hypothalamic neuronal cell line (GN11), by confocal microscopy analysis, flotation on density gradient, and coimmunoprecipitation experiments. Following the anti-PrPc antibody-mediated stimulation of live GN11 cells, we observed that PrPc clustered on plasma membrane domains rich in Cav-1 in which Fyn kinase converged to be activated. After these events, a signaling cascade through p42/44 MAP kinase (Erk 1/2) was triggered, suggesting that following translocations from rafts to caveolae or caveolae-like domains PrPc could interact with Cav-1 and induce signal transduction events.

3.856 Presenilin-Dependent γ-Secretase on Plasma Membrane and Endosomes Is Functionally Distinct
Fukumori, A. et al
Biochemistry, ***45***, *4907-4914 (2006)*

The presenilin (PS)/γ-secretase complex, which contains not only PS but also Aph-1, PEN-2, and nicastrin, mediates proteolysis of the transmembrane domain of β-amyloid protein precursor (βAPP). Intramembrane proteolysis occurs at the interface between the membrane and cytosol (ε-site) and near the middle of the transmembrane domain (γ-site), generating the βAPP intracellular domain (AICD) and Alzheimer disease-associated Aβ, respectively. Both cleavage sites exhibit some diversity. Changes in the precision of γ-cleavage, which potentially results in secretion of pathogenic Aβ42, have been intensively studied, while those of ε-cleavage have not. Although a number of PS-associated factors have been identified, it is unclear whether any of them physiologically regulate the precision of cleavage by PS/γ-secretase. Moreover, there is currently no clear evidence of whether PS/γ-secretase function differs according to the subcellular site. Here, we show that endocytosis affects the precision of PS-dependent ε-cleavage in cell culture. Relative production of longer AICDε49 increases on the plasma membrane, whereas that of shorter AICDε51 increases on endosomes; however, this occurs without a concomitant major change in the precision of cleavage at γ-sites. Moreover, very similar changes in the precision of ε-cleavage are induced by alteration of the pH. Our findings demonstrate that the precision of ε-cleavage by PS/γ-secretase changes depending upon the conditions and the subcellular location. These results suggest that the precision of cleavage by the PS/γ-secretase complex may be physiologically regulated by the subcellular location and conditions.

3.857 Structure and Cholesterol Dynamics of Caveolae/Raft and Nonraft Plasma Membrane Domains
Gallegos, A.M., Storey, S.M., Kier, A.B., Schroeder, F. and Ball, J.M.
Biochemistry, ***45***, *12100-12116 (2006)*

Despite recognition that the plasma membrane (PM) is comprised of lipid raft domains that are key organizing sites of multiple signaling pathways and other cell functions, limited information is available regarding the structure and function in sterol dynamics of these microdomains. To begin to resolve these issues, MDCK membranes were subfractionated by three different techniques to produce (i) detergent-resistant membranes (DRM) and detergent-soluble membranes (DSM), (ii) nondetergent caveolae/rafts (NDCR), and (iii) nondetergent, affinity-purified caveolae/rafts (ACR) and noncaveolae/nonrafts (NR). ACR exhibited the least cross contamination with other PM domains or intracellular membranes, in marked contrast to DRM that contained the highest level of cross contaminants. Spectral properties of dehydroergosterol (DHE), a naturally occurring fluorescent sterol, showed that ACR, NDCR, and NR did not contain crystalline sterol, consistent with the lack of crystalline sterol in PM of intact cells. In contrast, DRM contained significant levels of crystalline sterol. Fluorescence polarization of membrane probes showed that ACR were the least fluid and had the highest transbilayer fluidity gradient, the most liquid ordered phase, and the sterol dynamics most responsive to sterol carrier protein-2 (SCP-2). In contrast,

DRM had structural properties similar to those of NR, anomalous (very fast) spontaneous sterol dynamics, and sterol dynamics that were unresponsive to SCP-2. Differences between the structural and functional properties of DRM and those of the nondetergent preparations (ACR and NDCR) were not due to the presence of detergent. A nondetergent, affinity-purified (ACR) lipid domain fraction isolated from MDCK cells for the first time revealed unique structural (noncrystalline sterol, liquid-ordered, high transbilayer fluidity gradient) and functional (cholesterol dynamics) properties of lipid rafts as compared to nonrafts (NR). In summary, this study showed membrane microdomains (rafts/caveolae) isolated by three different methodologies have unique structural, functional, and organizational characteristics.

3.858 A role for ion channels in glioma cell invasion
McFerrin, M.B. and Sontheimer, H.
Neuron Glia Biol., ***2(1)***, *39-49 (2006)*

Many cells, including neuronal and glial progenitor cells, stem cells and microglial cells, have the capacity to move through the extracellular spaces of the developing and mature brain. This is particularly pronounced in astrocyte-derived tumors, gliomas, which diffusely infiltrate the normal brain. Although a significant body of literature exists regarding signals that are involved in the guidance of cells and their processes, little attention has been paid to cell-shape and cell-volume changes of migratory cells. However, extracellular spaces in the brain are very narrow and represent a major obstacle that requires cells to dynamically regulate their volume. Recent studies in glioma cells show that this involves the secretion of Cl^- and K^+ with water. Pharmacological inhibition of Cl^- channels impairs their ability to migrate and limits tumor progression in experimental tumor models. One Cl^--channel inhibitor, chlorotoxin, is currently in Phase II clinical trials to treat malignant glioma. This article reviews our current knowledge of cell-volume changes and the role of ion channels during the migration of glioma cells. It also discusses evidence that supports the importance of channel-mediated cell-volume changes in the migration of immature neurons and progenitor cells during development. New unpublished data is presented, which demonstrates that Cl^- and K^+ channels involved in cell shrinkage localize to lipid-raft domains on the invadipodia of glioma cells and that their presence might be regulated by trafficking of these proteins in and out of lipid rafts.

3.859 Comparative proteomics of glycosomes from bloodstream form and procyclic culture form *Trypanosoma brucei brucei*
Colasante, C., Ellis, M., Ruppert, T. And Voncken, F.
Proteomics, ***6(11)***, *3275-3293 (2006)*

Peroxisomes are present in nearly every eukaryotic cell and compartmentalize a wide range of important metabolic processes. Glycosomes of Kinetoplastid parasites are peroxisome-like organelles, characterized by the presence of the glycolytic pathway. The two replicating stages of *Trypanosoma brucei brucei*, the mammalian bloodstream form (BSF) and the insect (procyclic) form (PCF), undergo considerable adaptations in metabolism when switching between the two different hosts. These adaptations involve also substantial changes in the proteome of the glycosome. Comparative (non-quantitative) analysis of BSF and PCF glycosomes by nano LC-ESI-Q-TOF-MS resulted in the validation of known functional aspects of glycosomes and the identification of novel glycosomal constituents.

3.860 Proteomic Analysis of Mature Melanosomes from the Retinal Pigmented Epithelium
Azarian, S.M., McLeod, I., Lillo, C., Gibbs, D., Yates, J.R. and Williams, D.S.
J. Proteome Res., ***5(3)***, *521-529 (2006)*

The protein content of melanosomes in the retinal pigment epithelium (RPE) was analyzed by mass spectrometry. More than 100 proteins were found to be common to two out of three variations of sample preparation. Some proteins normally associated with other organelles were detected. Several lysosomal enzymes were detected, with the presence of cathepsin D confirmed by immunoelectron microscopy, thus supporting the previously suggested notion that melanosomes may contribute to the degradation of ingested photoreceptor outer segment disks.

3.861 Insights into the membrane proteome of rat liver peroxisomes: Microsomal glutathione-S-transferase is shared by both subcellular compartments
Islinger, M., Lüers, G.H., Zischka, H., Ueffing, M. and Völkl, A.
Proteomics, ***6(3),*** *804-816 (2006)*

Peroxisomes are ubiquitous “multipurpose” organelles of eukaryotic cells. Their matrix enzymes catalyze mainly catabolic and anabolic reactions of lipid metabolism, thus contributing to the regulation of lipid homeostasis. Since most metabolites must be actively transported across the peroxisomal membrane and since individual proteins and protein complexes play functional roles in such transport processes, we analyzed the peroxisomal membrane proteome. Benzyldimethyl-*n*-hexadecylammoniumchloride (16-BAC)/SDS-2-D-PAGE and mass spectrometry were used to characterize the proteomes of highly purified “light” and “heavy” peroxisomes of rat liver obtained by density gradient centrifugation. In both populations, the major integral membrane proteins could be detected in high concentrations, verifying 16-BAC/SDS-2-D-PAGE as a suitable tool for the preparation of membrane proteomes destined for mass spectrometric analysis. Both reliable and reproducible detection of a distinct set of microsomal (ER) membrane proteins, including microsomal glutathione-S-transferase (mGST), in light and heavy peroxisomal fractions was also possible. Compared with the abundance of most microsomal membrane proteins, we found mGST to be specifically enriched in peroxisomal membrane fractions. Furthermore, C terminus epitope-tagged mGST versions were localized at least in part to peroxisomes in different mammalian cell lines. Taken together, these data suggest that the peroxisomal GST is not a mere ER-contaminant, but a *bona fide* protein comprising the membrane proteome of both intracellular compartments. In addition, we could detect several mitochondrial proteins in light peroxisome fractions. This finding may likely indicate a physical association of light peroxisomes with mitochondria, since the organelles could be partly separated by mechanical stress. Whether this association is of functional importance awaits further investigation.

3.862 Mitochondrial protein patterns correlating with impaired insulin secretion from INS-1E cells exposed to elevated glucose concentrations
Nyblom, H.K., Thorn, K., Ahmed, M. and Bergsten, P.
*Proteomics, **6(19)**, 5193-5198 (2006)*

Extended hyperglycaemia leads to impaired glucose-stimulated insulin secretion (GSIS) and eventually β-cell apoptosis in individuals with type 2 diabetes mellitus. In an attempt to dissect mechanisms behind the detrimental effects of glucose, we focused on measuring changes in expression patterns of mitochondrial proteins. Impaired GSIS was observed from INS-1E cells cultured for 5 days at 20 or 27 mM glucose compared to cells cultured at 5.5 or 11 mM glucose. After culture, mitochondria were isolated from the INS-1E cells by differential centrifugation. Proteins of the mitochondrial fraction were bound to a strong anionic surface (SAX2) protein array and mass spectra generated by SELDI-TOF-MS. Analysis of the spectra revealed proteins with expression levels that correlated with the glucose concentration of the culture medium. Indeed, such differentially expressed proteins created patterns of protein changes, which correlated with impairment of GSIS. In conclusion, the study reveals the first glucose-induced differentially expressed patterns of β-cell mitochondrial proteins obtained by SELDI-TOF-MS.

3.863 Proteomic analysis of detergent-resistant membranes from *Candida albicans*
Insenser, M., Nombela, C., Molero, G. and Gil, C.
*Proteomics, **6, Suppl. 1.,** S74-S81 (2006)*

Lipid rafts are membrane microdomains with a higher amount of saturated fatty acids and sterols than the rest of the membrane. They are more resistant to the action of non-anionic detergents, and are called, for this reason, detergent-resistant membranes (DRMs). Lipid rafts are involved in many cellular processes, like signaling, cytokinesis, response to environment, *etc*., and therefore must contain important proteins. We have obtained a fraction enriched in proteins from *Candida albicans* DRMs. The sample has been analyzed by SDS-PAGE and 29 proteins have been identified including markers for lipid rafts in *Saccharomyces cerevisiae*, like Pma1p and a glycosylphosphatidylinositol (GPI)-anchored protein belonging to the Phr family. Ecm33p, a GPI-anchored protein involved in cell wall biogenesis, has been found for the first time in lipid rafts. We have also identified proteins implicated in protein glycosylation, like the mannosyltransferases Mnn7p, Pmt2p and Mnt1p; proteins involved in lipid metabolism, like Erg11p and Scs7p; and heat shock proteins, like Ssa1p and Hsp90p. Most of the proteins identified are located in plasma, mitochondrial, Golgi or ER membranes, supporting the postulated existence of lipid-raft domains in all the membranes.

3.864 Functionally different pools of Shiga toxin receptor, globotriaosyl ceramide, in HeLa cells
Falguierres, T., Römer, W., Amessou, M., Afonso, C., Wolf, C., Tabet, J-C., Lamaze, C. and Johannes, L.
*FEBS J., **273(22)**, 5205-5218 (2006)*

Many studies have investigated the intracellular trafficking of Shiga toxin, but very little is known about the underlying dynamics of its cellular receptor, the glycosphingolipid globotriaosyl ceramide. In this study, we show that globotriaosyl ceramide is required not only for Shiga toxin binding to cells, but also for its intracellular trafficking. Shiga toxin induces globotriaosyl ceramide recruitment to detergent-resistant membranes, and subsequent internalization of the lipid. The globotriaosyl ceramide pool at the plasma membrane is then replenished from internal stores. Whereas endocytosis is not affected in the recovery condition, retrograde transport of Shiga toxin to the Golgi apparatus and the endoplasmic reticulum is strongly inhibited. This effect is specific, as cholera toxin trafficking on GM_1 and protein biosynthesis are not impaired. The differential behavior of both toxins is also paralleled by the selective loss of Shiga toxin association with detergent-resistant membranes in the recovery condition, and comparison of the molecular species composition of plasma membrane globotriaosyl ceramide indicates subtle changes in favor of unsaturated fatty acids. In conclusion, this study demonstrates the dynamic behavior of globotriaosyl ceramide at the plasma membrane and suggests that globotriaosyl ceramide-specific determinants, possibly its molecular species composition, are selectively required for efficient retrograde sorting on endosomes, but not for endocytosis.

3.865 Isolation and analysis of lipid rafts in cell-cell interactions
Landry, A. and Xavier, r.
*Methods Mol. Biol., **341**, 251-282 (2006)*

Lipid rafts are dynamic structures made up of proteins and lipids that float freely within the liquid-disordered bilayer of cellular membranes and have the ability to cluster to form larger, more-ordered platforms. These clustered structures have been identified in all cell types and have been shown to play critical roles in signal transduction, cellular transport, and cell-cell communication. Lipid rafts also have been implicated in facilitating bacterial/viral entry into host cells and in human disease, highlighting the significance of understanding the role lipid rafts play in physiological and pathological signaling outcomes. In this chapter, we provide protocols to isolate lipid rafts from polarized and nonpolarized cells and outline novel technologies to analyze signal transduction cascades in vivo.

3.866 Cardiac mitochondrial connexin 43 regulates apoptosis
Goubaeva, F. et al
*Biochem. Biophys. Res. Comm., **352(1)**, 97-103 (2007)*

Connexin 43 (Cx43) is thought to be present largely in the plasma membrane and its function solely to provide low resistance electrical connection between myocytes. A recent report suggested the presence of Cx43 in the mitochondria as well. We confirmed the presence of Cx43 in the mitochondria isolated from adult rat ventricles with the Cx43 immunoreactivity fractionating to the outer mitochondrial membrane. Mitochondrial Cx43 is mostly phosphorylated only detected by a phospho-specific antibody. Using a Ca^{2+}-sensitive electrode and Western blot, we showed that the gap junction inhibitors 18-β-glycyrrhetinic acid (β-GA), oleamide, and heptanol all induced concomitant release of Ca^{2+} and cytochrome *C* in isolated mitochondria whereas the inactive analog 18-β-glycyrrhizic acid failed to do so. In low density neonatal myocyte culture with no appreciable cell–cell contacts, β-GA induced apoptosis as assessed by TUNEL staining. Our results suggest a novel role of Cx43 as a regulator of mitochondrial physiology and myocyte apoptosis.

3.867 Signaling proteins in raft-like microdomains are essential for Ca2+ wave propagation in glial cells
Weerth, S.H., Holtzclaw, L.A. and Russell, J.T.
*Cell Calsium, **41(1)**, 155-167 (2007)*

The hypothesis that calcium signaling proteins segregate into lipid raft-like microdomains was tested in isolated membranes of rat oligodendrocyte progenitor (OP) cells and astrocytes using Triton X-100 solubilization and density gradient centrifugation. Western blot analysis of gradient fractions showed co-localization of caveolin-1 with proteins involved in the Ca^{2+} signaling cascade. These included agonist receptors, $P2Y_1$, and M_1, TRPC1, IP_3R2, ryanodine receptor, as well as the G protein $G\alpha_q$ and Homer. Membranes isolated from agonist-stimulated astrocytes showed an enhanced recruitment of phospholipase C (PLCβ1), IP_3R2 and protein kinase C (PKC-α) into lipid raft fractions. IP_3R2, TRPC1 and Homer co-immunoprecipitated, suggesting protein–protein interactions. Disruption of rafts by cholesterol depletion using methyl-β-cyclodextrin (β-MCD) altered the distribution of caveolin-1 and GM1 to non-raft fractions with higher densities. β-MCD-induced disruption of rafts inhibited agonist-evoked Ca^{2+} wave propagation

in astrocytes and attenuated wave speeds. These results indicate that in glial cells, Ca^{2+} signaling proteins might exist in organized membrane microdomains, and these complexes may include proteins from different cellular membrane systems. Such an organization is essential for Ca^{2+} wave propagation.

3.868 Characterisation of lipofuscin-like lysosomal inclusion bodies from human placenta
Schröder, B., Elsässer, H-P-. Schmidt, B. and Hasilik, A.
FEBS Lett., ***581(1)***, *102-108 (2007)*

A structural hallmark of lysosomes is heterogeneity of their contents. We describe a method for isolation of particulate materials from human placental lysosomes. After a methionine methyl ester-induced disruption of lysosomes and two density gradient centrifugations we obtained a homogeneous membrane fraction and another one enriched in particulate inclusions. The latter exhibited a yellow-brown coloration and contained bodies lacking a delimiting membrane, which were characterised by a granular pattern and high electron density. The lipofuscin-like inclusion materials were rich in tripeptidyl peptidase I, β-glucuronidase, acid ceramidase and apolipoprotein D and contained proteins originating from diverse subcellular localisations.
Here we show that human term placenta contains lipofuscin-like lysosomal inclusions, a phenomenon usually associated with senescence in postmitotic cells. These findings imply that a simple pelleting of a lysosomal lysate is not appropriate for the isolation of lysosomal membranes, as the inclusions tend to be sedimented with the membranes.

3.869 Activation-induced endocytosis of the raft-associated transmembrane adaptor protein LAB/NTAL in B lymphocytes: evidence for a role in internalization of the B cell receptor
Mutch, C.M. et al
Int. Immunol., ***19(1)***, *19-30 (2007)*

Linker for activation of B cell (LAB)/non-T cell activation linker (NTAL) and phosphoprotein associated with glycophospholipid-enriched membrane microdomain (PAG)/Csk-binding protein (Cbp) are raft-associated transmembrane adaptor proteins with distinct functions in immediate/early phases of receptor signaling pathways. Heterogeneous rafts are thought to compartmentalize membrane-associated signaling events. In order to investigate the subcellular localization of LAB/NTAL and PAG/Cbp, they were expressed as fluorescent chimeric fusion proteins in a human B cell line and their distribution was examined, along with the corresponding endogenous proteins, before and after B cell receptor (BCR) stimulation. Both adaptors were distributed predominantly at the plasma membrane in resting cells and co-clustered with other raft-associated proteins; however, they distributed differently in buoyant membranes isolated by either detergent resistance or non-detergent methods, indicating that they might localize to distinct rafts. After activation, LAB/NTAL was internalized and co-localized with the BCR while PAG/Cbp remained on the cell surface. BCR internalization was reduced in LAB/NTAL-deficient murine B cells, suggesting a regulatory role for LAB/NTAL in activation-induced internalization of the BCR. The cytoplasmic domain of LAB/NTAL, and not the transmembrane/juxtamembrane region, was found to be essential for its internalization.

3.870 Release of outer membrane vesicles by Gram-negative bacteria is a novel envelope stress response
McBroom, A.J. and Kuehn, M.J.
Mol. Microbiol., ***63(2)***, *545-558 (2007)*

Conditions that impair protein folding in the Gram-negative bacterial envelope cause stress. The destabilizing effects of stress in this compartment are recognized and countered by a number of signal transduction mechanisms. Data presented here reveal another facet of the complex bacterial stress response, release of outer membrane vesicles. Native vesicles are composed of outer membrane and periplasmic material, and they are released from the bacterial surface without loss of membrane integrity. Here we demonstrate that the quantity of vesicle release correlates directly with the level of protein accumulation in the cell envelope. Accumulation of material occurs under stress, and is exacerbated upon impairment of the normal housekeeping and stress-responsive mechanisms of the cell. Mutations that cause increased vesiculation enhance bacterial survival upon challenge with stressing agents or accumulation of toxic misfolded proteins. Preferential packaging of a misfolded protein mimic into vesicles for removal indicates that the vesiculation process can act to selectively eliminate unwanted material. Our results demonstrate that production of bacterial outer membrane vesicles is a fully independent, general envelope stress

response. In addition to identifying a novel mechanism for alleviating stress, this work provides physiological relevance for vesicle production as a protective mechanism.

3.871 Down-regulation of dopamine transporter by iron chelation *in vitro* is mediated by altered trafficking, not synthesis
Wiesinger, J.A.
J. Neurochem., ***100***, *167-179 (2007)*

Neurological development and functioning of dopamine (DA) neurotransmission is adversely affected by iron deficiency in early life. Iron-deficient rats demonstrate significant elevations in extracellular DA and a reduction in dopamine transporter (DAT) densities in the caudate putamen and nucleus accumbens. To explore possible mechanisms by which cellular iron concentrations control DAT functioning, endogenous DAT-expressing PC12 cells were used to determine the effect of iron chelation on DAT protein and mRNA expression patterns. In addition, we used human DAT (hDAT)-transfected Neuro2a (N2A) cells to examine DAT degradation and trafficking patterns. A 50 μ**m** treatment for 24 h with the iron chelator, desferrioxamine (DFO), significantly decreased dopamine uptake in a dose-dependent manner, with no apparent change in K_m, in both PC12 and N2A cells. Reduced DA uptake was accompanied by concentration- and time-dependent reductions in total DAT protein levels in both cell lines. Exposure to increasing concentrations of DFO did not significantly alter DAT mRNA in either PC12 or N2A cells. However, DAT degradation rates increased three–fivefold in both cell types exposed to 50 μ**m** DFO for 24 h. Biotinylation studies in N2A cells indicate a more dramatic loss of DAT in the membrane fraction, while **OptiPrep** fractionation experiments revealed an increase in lysosomal DAT with iron chelation. Inhibition of protein kinase C activation with staurosporin prevented the effect of iron chelation on DAT function, suggesting that *in vitro* iron chelation affects DAT primarily through the effects on trafficking rather than on synthesis.

3.872 Inhibition of the Secretory Pathway by Foot-and-Mouth Disease Virus 2BC Protein Is Reproduced by Coexpression of 2B with 2C, and the Site of Inhibition Is Determined by the Subcellular Location of 2C
Moffat, K. et al
J. Virol., ***81(3)***, *1129-1139 (2007)*

Infection of cells with picornaviruses can lead to a block in protein secretion. For poliovirus this is achieved by the 3A protein, and the consequent reduction in secretion of proinflammatory cytokines and surface expression of major histocompatibility complex class I proteins may inhibit host immune responses in vivo. Foot-and-mouth disease virus (FMDV), another picornavirus, can cause persistent infection of ruminants, suggesting it too may inhibit immune responses. Endoplasmic reticulum (ER)-to-Golgi apparatus transport of proteins is blocked by the FMDV 2BC protein. The observation that 2BC is processed to 2B and 2C during infection and that individual 2B and 2C proteins are unable to block secretion stimulated us to study the effects of 2BC processing on the secretory pathway. Even though 2BC was processed rapidly to 2B and 2C, protein transport to the plasma membrane was still blocked in FMDV-infected cells. The block could be reconstituted by coexpression of 2B and 2C, showing that processing of 2BC did not compromise the ability of FMDV to slow secretion. Under these conditions, 2C was located to the Golgi apparatus, and the block in transport also occurred in the Golgi apparatus. Interestingly, the block in transport could be redirected to the ER when 2B was coexpressed with a 2C protein fused to an ER retention element. Thus, for FMDV a block in secretion is dependent on both 2B and 2C, with the latter determining the site of the block.

3.873 Membrane Cholesterol Content Modulates ClC-2 Gating and Sensitivity to Oxidative Stress
Hinzpeter, A. et al
J. Biol. Chem., ***282(4)***, *2423-2432 (2007)*

ClC-2 is a broadly expressed member of the voltage-gated ClC chloride channel family. In this study, we aimed to evaluate the role of the membrane lipid environment in ClC-2 function, and in particular the effect of cholesterol and ClC-2 distribution in membrane microdomains. Detergent-resistant and detergent-soluble microdomains (DSM) were isolated from stably transfected HEK293 cells by a discontinuous **OptiPrep** gradient. ClC-2 was found concentrated in detergent-insoluble membranes in basal conditions and relocalized to DSM upon cholesterol depletion by methyl-β-cyclodextrin. As assessed by patch clamp recordings, relocalization was accompanied by acceleration of the activation kinetics of the channel. A

similar distribution and activation pattern were obtained when cells were treated with the oxidant *tert*-butyl hydroperoxide and after ATP depletion. In both cases activation was prevented by cholesterol enrichment of cells. We conclude that the cholesterol environment regulates ClC-2 activity, and we provide evidence that the increase in ClC-2 activity in response to acute oxidative or metabolic stress involves relocalization of this channel to DSM.

3.874 Filamin links cell shape and cytoskeletal structure to Rho regulation by controlling accumulation of p190RhoGAP in lipid rafts
Mammoto, A., Huang, S. and Ingber, D.E.
*J. Cell Sci., **120**, 456-467 (2007)*

Cytoskeleton-dependent changes in the activity of the small GTPase Rho mediate the effects of cell shape on cell function; however, little is known about how cell spreading and related distortion of the cytoskeleton regulate Rho activity. Here we show that rearrangements of the actin cytoskeleton associated with early phases of cell spreading in human microvascular endothelial (HMVE) cells suppress Rho activity by promoting accumulation of p190RhoGAP in lipid rafts where it exerts its Rho inhibitory activity. p190RhoGAP is excluded from lipid rafts and Rho activity increases when cell rounding is induced or the actin cytoskeleton is disrupted, and p190RhoGAP knockdown using siRNA prevents Rho inactivation by cell spreading. Importantly, cell rounding fails to prevent accumulation of p190RhoGAP in lipid rafts and to increase Rho activity in cells that lack the cytoskeletal protein filamin. Moreover, filamin is degraded in spread cells and cells that express a calpain-resistant form of filamin exhibit high Rho activity even when spread. Filamin may therefore represent the missing link that connects cytoskeleton-dependent changes of cell shape to Rho inactivation during the earliest phases of cell spreading by virtue of its ability to promote accumulation of p190RhoGAP in lipid rafts.

3.875 Lethal recessive myelin toxicity of prion protein lacking its central domain
Baumann, F. et al
*EMBO J., **26**, 538-547 (2007)*

PrP^C-deficient mice expressing prion protein variants with large amino-proximal deletions (termed $PrP\Delta_F$) suffer from neurodegeneration, which is rescued by full-length PrP^C. We now report that expression of PrP Δ_{CD}, a PrP variant lacking 40 central residues (94–134), induces a rapidly progressive, lethal phenotype with extensive central and peripheral myelin degeneration. This phenotype was rescued dose-dependently by coexpression of full-length PrP^C or PrP^C lacking all octarepeats. Expression of a PrP^C variant lacking eight residues (114–121) was innocuous in the presence or absence of full-length PrP^C, yet enhanced the toxicity of $PrP\Delta_{CD}$ and diminished that of $PrP\Delta_F$. Therefore, deletion of the entire central domain generates a strong recessive-negative mutant of PrP^C, whereas removal of residues 114–121 creates a partial agonist with context-dependent action. These findings suggest that myelin integrity is maintained by a constitutively active neurotrophic protein complex involving PrP^C, whose effector domain encompasses residues 94–134.

3.876 c-Jun Downregulation by HDAC3-Dependent Transcriptional Repression Promotes Osmotic Stress-Induced Cell Apoptosis
Xia, Y. et al
*Mol. Cell, **25**, 219-232 (2007)*

c-Jun, a major transcription factor in the activating protein 1 (AP-1) family of regulatory proteins, is activated by many physiologic and pathologic stimuli. However, whether c-*jun* is regulated by epigenetic modification of chromatin structure is not clear. We showed here that c-*jun* was transcriptionally repressed in response to osmotic stress via a truncated HDAC3 generated by caspase-7-dependent cleavage at aspartic acid 391. The activation of caspase-7, which is independent of cytochrome *c* release and activation of caspase-9 and caspase-12, depends on activation of caspase-8, which in turn requires MEK2 activity and secretion of FAS ligand. The cell apoptosis induced by the truncated HDAC3 or enhanced by c-Jun deficiency during osmotic stress was suppressed by exogenous expression of c-Jun, indicating that the downregulation of c-Jun by HDAC3-dependent transcriptional repression plays a role in regulating cell survival and apoptosis.

3.877 Heterogeneity of Raft-Type Membrane Microdomains Associated with VP4, the Rotavirus Spike Protein, in Caco-2 and MA 104 Cells
Delmas, O. Et al

J. Virol., ***81(4)***, *1610-1618 (2007)*

Previous studies have shown that rotavirus virions, a major cause of infantile diarrhea, assemble within small intestinal enterocytes and are released at the apical pole without significant cell lysis. In contrast, for the poorly differentiated kidney epithelial MA 104 cells, which have been used extensively to study rotavirus assembly, it has been shown that rotavirus is released by cell lysis. The subsequent discovery that rotavirus particles associate with raft-type membrane microdomains (RTM) in Caco-2 cells provided a simple explanation for rotavirus polarized targeting. However, the results presented here, together with those recently published by another group, demonstrate that rotavirus also associates with RTM in MA 104 cells, thus indicating that a simple interaction of rotavirus with rafts is not sufficient to explain its apical targeting in intestinal cells. In the present study, we explore the possibility that RTM may have distinct physicochemical properties that may account for the differences observed in the rotavirus cell cycle between MA 104 and Caco-2 cells. We show here that VP4 association with rafts is sensitive to cholesterol extraction by methyl-ß-cyclodextrin treatment in MA 104 cells and insensitive in Caco-2 cells. Using the VP4 spike protein as bait, VP4-enriched raft subsets were immunopurified. They contained 10 to 15% of the lipids present in total raft membranes. We found that the nature and proportion of phospholipids and glycosphingolipids were different between the two cell lines. We propose that this raft heterogeneity may support the cell type dependency of virus assembly and release.

3.878 **Identification of Differentially Activated Cell-Signaling Networks Associated with Pichinde Virus Pathogenesis by Using Systems Kinomics**
Bowick, G.C. et al
J. Virol., ***81(4)***, *1923-1933 (2007)*

Phosphorylation plays a key role in regulating many signaling pathways. Although studies investigating the phosphorylated forms of signaling pathways are now commonplace, global analysis of protein phosphorylation and kinase activity has lagged behind genomics and proteomics. We have used a kinomics approach to study the effect of virus infection on host cell signaling in infected guinea pigs. Delineating the host responses which lead to clearance of a pathogen requires the use of a matched, comparative model system. We have used two passage variants of the arenavirus Pichinde, used as a biosafety level 2 model of Lassa fever virus as it produces similar pathologies in guinea pigs and humans, to compare the host cell responses between infections which lead to either a mild, self-limiting infection or lethal disease. Using this model, we can begin to understand the differences in signaling events which give rise to these markedly different outcomes. By contextualizing these data using pathway analysis, we have identified key differences in cellular signaling matrices. By comparing these differentially involved networks, we have identified a number of key signaling "nodes" which show differential phosphorylations between mild and lethal infections. We believe that these nodes provide potential targets for the development of antiviral therapies by acting at the level of the host response rather than by directly targeting viral proteins.

3.879 **The reduced GM-CSF priming of ROS production in granulocytes from patients with myelodysplasia is associated with an impaired lipid raft formation**
Fuhler, G.M., Blom, N.R., Coffer, P.J., Drayer, A.L. and Vellenga, E.
J. Leukoc. Biol., ***81***, *449-457 (2007)*

Patients with myelodysplasia (MDS) show an impaired reactive oxygen species (ROS) production in response to fMLP stimulation of GM-CSF-primed neutrophils. In this study, we investigated the involvement of lipid rafts in this process and showed that treatment of neutrophils with the lipid raft-disrupting agent methyl-ß-cyclodextrin abrogates fMLP-induced ROS production and activation of ERK1/2 and protein kinase B/Akt, two signal transduction pathways involved in ROS production in unprimed and GM-CSF-primed neutrophils. We subsequently showed that there was a decreased presence of Lyn, $gp91^{phox}$, and $p22^{phox}$ in lipid raft fractions from neutrophils of MDS. Furthermore, the plasma membrane expression of the lipid raft marker GM1, which increases upon stimulation of GM-CSF-primed cells with fMLP, was reduced significantly in MDS patients. By electron microscopy, we showed that the fMLP-induced increase in GM1 expression in GM-CSF-primed cells was a result of de novo synthesis, which was less efficient in MDS neutrophils. Taken together, these data indicate an involvement of lipid rafts in activation of signal transduction pathways leading to ROS production and show that in MDS neutrophils, an impaired lipid raft formation in GM-CSF-primed cells results in an impaired ROS production.

3.880 Novel peroxisomal protease Tysnd1 processes PTS1- and PTS2-containing enzymes involved in β-oxidation of fatty acids
Kurochkin, I.V. et al
*EMBO J., **26**, 835-845 (2007)*

Peroxisomes play an important role in β-oxidation of fatty acids. All peroxisomal matrix proteins are synthesized in the cytosol and post-translationally sorted to the organelle. Two distinct peroxisomal signal targeting sequences (PTSs), the C-terminal PTS1 and the N-terminal PTS2, have been defined. Import of precursor PTS2 proteins into the peroxisomes is accompanied by a proteolytic removal of the N-terminal targeting sequence. Although the PTS1 signal is preserved upon translocation, many PTS1 proteins undergo a highly selective and limited cleavage. Here, we demonstrate that Tysnd1, a previously uncharacterized protein, is responsible both for the removal of the leader peptide from PTS2 proteins and for the specific processing of PTS1 proteins. All of the identified Tysnd1 substrates catalyze peroxisomal β-oxidation. Tysnd1 itself undergoes processing through the removal of the presumably inhibitory N-terminal fragment. Tysnd1 expression is induced by the proliferator-activated receptor αagonist bezafibrate, along with the increase in its substrates. A model is proposed where the Tysnd1-mediated processing of the peroxisomal enzymes promotes their assembly into a supramolecular complex to enhance the rate of β-oxidation.

3.881 Relationships between the Sequence of α-Synuclein and its Membrane Affinity, Fibrillization Propensity, and Yeast Toxicity
Volles, M.J. and Lansbury, P.T.
*J. Mol. Biol., **366(5)**, 1510-1522 (2007)*

To investigate the α-synuclein protein and its role in Parkinson's disease, we screened a library of random point mutants both *in vitro* and in yeast to find variants in an unbiased way that could help us understand the sequence–phenotype relationship. We developed a rapid purification method that allowed us to screen 59 synuclein mutants *in vitro* and discovered two double-point mutants that fibrillized slowly relative to wild-type, A30P, and A53T α-synucleins. The yeast toxicity of all of these proteins was measured, and we found no correlation with fibrillization rate, suggesting that fibrillization is not necessary for synuclein-induced yeast toxicity. We found that β-synuclein was of intermediate toxicity to yeast, and γ-synuclein was non-toxic. Co-expression of Parkinson's disease-related genes DJ-1, parkin, Pink1, UCH-L1, or synphilin, with synuclein, did not affect synuclein toxicity. A second screen, of several thousand library clones in yeast, identified 25 non-toxic α-synuclein sequence variants. Most of these contained a mutation to either proline or glutamic acid that caused a defect in membrane binding. We hypothesize that yeast toxicity is caused by synuclein binding directly to membranes at levels sufficient to non-specifically disrupt homeostasis.

3.882 Asymmetric Localization of Calpain 2 during Neutrophil Chemotaxis
Nuzzi, P.A., Senetar, M.A., Huttenlocher, A.
*Mol. Biol. Cell, **18**, 795-805 (2007)*

Chemoattractants induce neutrophil polarization through localized polymerization of F-actin at the leading edge. The suppression of rear and lateral protrusions is required for efficient chemotaxis and involves the temporal and spatial segregation of signaling molecules. We have previously shown that the intracellular calcium-dependent protease calpain is required for cell migration and is involved in regulating neutrophil chemotaxis. Here, we show that primary neutrophils and neutrophil-like HL-60 cells express both calpain 1 and calpain 2 and that chemoattractants induce the asymmetric recruitment of calpain 2, but not calpain 1, to the leading edge of polarized neutrophils and differentiated HL-60 cells. Using time-lapse microscopy, we show that enrichment of calpain 2 at the leading edge occurs during early pseudopod formation and that its localization is sensitive to changes in the chemotactic gradient. We demonstrate that calpain 2 is recruited to lipid rafts and that cholesterol depletion perturbs calpain 2 localization, suggesting that its enrichment at the front requires proper membrane organization. Finally, we show that catalytic activity of calpain is required to limit pseudopod formation in the direction of chemoattractant and for efficient chemotaxis. Together, our findings identify calpain 2 as a novel component of the frontness signal that promotes polarization during chemotaxis.

3.883 PALS1 Regulates E-Cadherin Trafficking in Mammalian Epithelial Cells
Wang, Q., Chen, X-W. and Margolis, B.
*Mol. Biol. Cell, **18**, 874-885 (2007)*

Protein Associated with *Lin Seven 1* (PALS1) is an evolutionarily conserved scaffold protein that targets to the tight junction in mammalian epithelia. Prior work in our laboratory demonstrated that the knockdown of PALS1 in Madin Darby canine kidney cells leads to tight junction and polarity defects. We have created new PALS1 stable knockdown cell lines with more profound reduction of PALS1 expression, and a more severe defect in tight junction formation was observed. Unexpectedly, we also observed a severe adherens junction defect, and both defects were corrected when PALS1 wild type and certain PALS1 mutants were expressed in the knockdown cells. We found that the adherens junction structural component E-cadherin was not effectively delivered to the cell surface in the PALS1 knockdown cells, and E-cadherin puncta accumulated in the cell periphery. The exocyst complex was also found to be mislocalized in PALS1 knockdown cells, potentially explaining why E-cadherin trafficking is disrupted. Our results suggest a broad and evolutionarily conserved role for the tight junction protein PALS1 in the biogenesis of adherens junction.

3.884 Role of the Sec61 Translocon in EGF Receptor Trafficking to the Nucleus and Gene Expression
Liao, H-J. and Carpenter, G.
*Mol. Biol. Cell, **18**, 1064-1072 (2007)*

The epidermal growth factor (EGF)-dependent trafficking of the intact EGF receptor to the nucleus and its requirement for growth factor induction of cyclin D and other genes has been reported. Unresolved is the mechanism by which this or other transmembrane proteins are excised from a lipid bilayer before nuclear translocalization. We report that, after the addition of EGF, the cell surface EGF receptor is trafficked to the endoplasmic reticulum (ER) where it associates with Sec61β, a component of the Sec61 translocon, and is retrotranslocated from the ER to the cytoplasm. Abrogation of Sec61β expression prevents EGF-dependent localization of EGF receptors to the nucleus and expression of cyclin D. This indicates that EGF receptors are trafficked from the ER to the nucleus by a novel pathway that involves the Sec61 translocon.

3.885 Conservation of the TRAPPII-specific subunits of a Ypt/Rab exchanger complex
Cox, R., Chen, S.H., Yoo, E. and Segev, N.
*BMC Evolutionary Biol., **7(12)**, 1-15 (2007)*

Background
Ypt/Rab GTPases and their GEF activators regulate intra-cellular trafficking in all eukaryotic cells. In *S. cerivisiae*, the modular TRAPP complex acts as a GEF for the Golgi gatekeepers: Ypt1 and the functional pair Ypt31/32. While TRAPPI, which acts in early Golgi, is conserved from fungi to animals, not much is known about TRAPPII, which acts in late Golgi and consists of TRAPPI plus three additional subunits.
Results
Here, we show a phylogenetic analysis of the three TRAPPII-specific subunits. One copy of each of the two essential subunits, Trs120 and Trs130, is present in almost every fully sequenced eukaryotic genome. Moreover, the primary, as well as the predicted secondary, structure of the Trs120- and Trs130-related sequences are conserved from fungi to animals. The mammalian orthologs of Trs120 and Trs130, NIBP and TMEM1, respectively, are candidates for human disorders. Currently, NIBP is implicated in signaling, and TMEM1 is suggested to have trans-membrane domains (TMDs) and to function as a membrane channel. However, we show here that the yeast Trs130 does not function as a trans-membrane protein, and the human TMEM1 does not contain putative TMDs. The non-essential subunit, Trs65, is conserved only among many fungi and some unicellular eukaryotes. Multiple alignment analysis of each TRAPPII-specific subunit revealed conserved domains that include highly conserved amino acids.
Conclusion
We suggest that the function of both NIBP and TMEM1 in the regulation of intra-cellular trafficking is conserved from yeast to man. The conserved domains and amino acids discovered here can be used for functional analysis that should help to resolve the differences in the assigned functions of these proteins in fungi and animals.

3.886 Transcriptome analysis reveals the population of dendritic RNAs and their redistribution by neural activity
Matsumoto, M., Setou, M. and Inokuchi, K.
*Neurosci. Res., **57**, 411-423 (2007)*

Subcellular localization of RNA is an efficient way to localize proteins to a specific region of a cell. The dendritic localization of RNAs underlies the establishment and maintenance of the synaptic functions of neuronal cells. A requirement for dendritic RNA localization and subsequent local translation has been demonstrated in several forms of experience-dependent synaptic plasticity. In spite of several attempts to identify these RNAs, the population of RNA species present in dendrites as a whole has not been well described. Here we show the results of microarray analyses with RNAs isolated from heavy portion of polysome (HP) fraction where RNA granules are enriched in and synaptosome fraction, prepared from the rat brain. These analyses revealed the complex nature of the dendritic RNA population, which included RNAs that were not expected to be in the dendrites. Neural activity caused by an electroconvulsive shock triggered a redistribution of the population of dendritic transcriptome towards the area of overlap between the HP and the synaptosome, which is assumed to be neck of spine. This redistribution may accompany some changes in the translatability of those transcriptome, which suggests complex mechanisms of local translation in response to synaptic inputs.

3.887 Retinoschisin Is a Peripheral Membrane Protein with Affinity for Anionic Phospholipids and Affected by Divalent Cations

Vijayasarathy, C., Takada, Y., Zeng, Y., Bush, R.A. and Sieving, P.A.
Invest. Ophtalmol. Vis. Sci., ***48****, 991-1000 (2007)*

PURPOSE. Retinoschisin (RS) is a retina-specific, secreted protein implicated in X-linked juvenile retinoschisis and essential for the structural and functional integrity of the retina. This biochemical characterization and ultrastructural localization of RS in intact murine retina was performed to further understanding of the molecular basis of its function.
METHODS. Subcellular fractions and fractions enriched in photoreceptor inner and outer segments were prepared from mouse retina by differential or density gradient ultracentrifugation. Immunoblot analysis was used to assess the expression of RS in various subcellular compartments and its fractionation into soluble phase on treatment of retinal cell membranes with several solubilizing reagents. RS–lipid interactions were evaluated by a protein–lipid overlay assay that used wild-type and mutant forms of RS discoidin domain glutathione S-transferase (GST) fusion proteins. The subcellular localization of RS in mouse retina was visualized by pre-embedding immunogold electron microscopy. Ultrastructure was evaluated by transmission electron microscopy.
RESULTS. RS was intimately associated with cell membranes of the retina. It was found to cluster on the outer leaflet of the plasma membrane of the photoreceptor inner segments, which synthesize and secrete it. It was released from the membrane at high pH, which is characteristic of a peripheral membrane protein. It was extracted from the membrane by the nonionic detergent NP-40, together with glycerophospholipids. Protein–lipid overlay assays indicated a preferential interaction between RS and anioic phospholipids. Extraction of RS from the membrane was inhibited by divalent cations. Photoreceptor inner segment morphology was markedly affected in $RS^{-/y}$ mice, which failed to express RS protein.
CONCLUSIONS. RS in intact retina is a peripheral membrane protein. Although distributed over the two membrane faces, RS is associated primarily with the outer leaflet of the inner segment plasma membrane through anionic phospholipids and divalent cations. RS's localization in photoreceptors and its biochemical properties suggest a functional role locally, at the site of secretion and membrane adhesion, in maintaining the photoreceptor inner segment stability and architecture.

3.888 Insulin-stimulated exocytosis of GLUT4 is enhanced by IRAP and its partner tankyrase

Yeh, T-Y.J., Sbodio, J.I., Tsun, Z-Y., Luo, B. and Chi, N-W.
Biochem. J., ***402****, 279-290 (2007)*

The glucose transporter GLUT4 and the aminopeptidase IRAP (insulin-responsive aminopeptidase) are the major cargo proteins of GSVs (GLUT4 storage vesicles) in adipocytes and myocytes. In the basal state, most GSVs are sequestered in perinuclear and other cytosolic compartments. Following insulin stimulation, GSVs undergo exocytic translocation to insert GLUT4 and IRAP into the plasma membrane. The mechanisms regulating GSV trafficking are not fully defined. In the present study, using 3T3-L1 adipocytes transfected with siRNAs (small interfering RNAs), we show that insulin-stimulated IRAP translocation remained intact despite substantial GLUT4 knockdown. By contrast, insulin-stimulated GLUT4 translocation was impaired upon IRAP knockdown, indicating that IRAP plays a role in GSV trafficking. We also show that knockdown of tankyrase, a Golgi-associated IRAP-binding protein that co-localizes with perinuclear GSVs, attenuated insulin-stimulated GSV translocation and glucose uptake without disrupting insulin-induced phosphorylation cascades. Moreover, iodixanol density gradient

analyses revealed that tankyrase knockdown altered the basal-state partitioning of GLUT4 and IRAP within endosomal compartments, apparently by shifting both proteins toward less buoyant compartments. Importantly, the afore-mentioned effects of tankyrase knockdown were reproduced by treating adipocytes with PJ34, a general PARP (poly-ADP-ribose polymerase) inhibitor that abrogated tankyrase-mediated protein modification known as poly-ADP-ribosylation. Collectively, these findings suggest that physiological GSV trafficking depends in part on the presence of IRAP in these vesicles, and that this process is regulated by tankyrase and probably its PARP activity.

3.889 **p56lck, LFA-1 and PI3K but not SHP-2 interact with GM1- or GM3-enriched microdomains in a CD4–p56lck association-dependent manner**
Barbat, C. et al
Biochem. J., ***402(3)***, *471-481 (2007)*

We previously showed that the association of CD4 and G_{M3} ganglioside induced by CD4 ligand binding was required for the down-regulation of adhesion and that aggregation of ganglioside-enriched domains was accompanied by transient co-localization of LFA-1 (lymphocyte function-associated antigen-1), PI3K (phosphoinositide 3-kinase) and CD4. We also showed that these proteins co-localized with the G_{M1} ganglioside that partially co-localized with G_{M3} in these domains. In the present study, we show that CD4–$p56^{lck}$ association in CD4 signalling is required for the redistribution of $p56^{lck}$, PI3K and LFA-1 in ganglioside-enriched domains, since ganglioside aggregation and recruitment of these proteins were not observed in a T-cell line (A201) expressing the mutant form of CD4 that does not bind $p56^{lck}$. In addition, we show that although these proteins associated in different ways with G_{M1} and G_{M3}, all of the associations were dependent on CD4–$p56^{lck}$ association. Gangliosides could associate with these proteins that differ in affinity binding and could be modified following CD4 signalling. Our results suggest that through these associations, gangliosides transiently sequestrate these proteins and consequently inhibit LFA-1-dependent adhesion. Furthermore, while structural diversity of gangliosides may allow association with distinct proteins, we show that the tyrosine phosphatase SHP-2 (Src homology 2 domain-containing protein tyrosine phosphatase 2), also required for the down-regulation of LFA-1-dependent adhesion, transiently and partially co-localized with PI3K and $p56^{lck}$ in detergent-insoluble membranes without association with G_{M1} or G_{M3}. We propose that CD4 ligation and binding with $p56^{lck}$ and their interaction with G_{M3} and/or G_{M1} gangliosides induce recruitment of distinct proteins important for CD4 signalling to form a multimolecular signalling complex.

3.890 **EDEM1 reveals a quality control vesicular transport pathway out of the endoplasmic reticulum not involving the COPII exit sites**
Zuber, C. et al
PNAS, ***104(11)***, *4407-4412 (2007)*

Immature and nonnative proteins are retained in the endoplasmic reticulum (ER) by the quality control machinery. Folding-incompetent glycoproteins are eventually targeted for ER-associated protein degradation (ERAD). EDEM1 (ER degradation-enhancing α-mannosidase-like protein 1), a putative mannose-binding protein, targets misfolded glycoproteins for ERAD. We report that endogenous EDEM1 exists mainly as a soluble glycoprotein. By high-resolution immunolabeling and serial section analysis, we find that endogenous EDEM1 is sequestered in buds that form along cisternae of the rough ER at regions outside of the transitional ER. They give rise to ≈150-nm vesicles scattered throughout the cytoplasm that are lacking a recognizable COPII coat. About 87% of the immunogold labeling was over the vesicles and ≈ 11% over the ER lumen. Some of the EDEM1 vesicles also contain Derlin-2 and the misfolded Hong Kong variant of α-1-antitrypsin, a substrate for EDEM1 and ERAD. Our results demonstrate the existence of a vesicle budding transport pathway out of the rough ER that does not involve the canonical transitional ER exit sites and therefore represents a previously unrecognized passageway to remove potentially harmful misfolded luminal glycoproteins from the ER.

3.891 **WD40 protein Mda1 is purified with Dnm1 and forms a dividing ring for mitochondria before Dnm1 in Cyanidioschyzon merolae**
Nishida, K., Yagisawa, F., Kuroiwa, H., Yoshida, Y. and Kuroiwa, T.
PNAS, ***104(11)***, *4736-4741 (2007)*

Mitochondria are not produced *de novo* but are maintained by division. Mitochondrial division is a coordinated process of positioning and constriction of the division site and fission of double membranes, in which dynamin-related protein is believed to mediate outer membrane fission. Part of the mitochondrial

division machinery was purified from M phase-arrested *Cyanidioschyzon merolae* cells through biochemical fractionation. The dynamin-related protein Dnm1 was one of the two major proteins in the purified fraction and was accompanied by a newly identified protein CMR185C, named Mda1. Mda1 contained a predictable coiled-coil region and WD40 repeats, similarly to Mdv1 and Caf4 in yeasts. Immunofluorescence and immunoelectron microscopy showed that Mda1 localizes as a medial belt or ring on the mitochondrial outer surface throughout the division. The ring formation of Mda1 followed the plane of the ring of FtsZ, a protein that resides in the matrix. Dnm1 consistently colocalized with Mda1 only in the late stages of division. Mda1 protein was expressed through S to M phases and was phosphorylated specifically in M phase when Mda1 transformed from belt into foci and became colocalizing with Dnm1. Dephosphorylation of Mda1 *in vitro* increased its sedimentation coefficient, suggesting conformational changes of the macromolecule. Disassembly of the purified mitochondrial division machinery was performed by adding GTP to independently release Dnm1, suggesting that Mda1 forms a stable homo-oligomer by itself as a core structure of the mitochondrial division machinery.

3.892 The novel cargo Alcadein induces vesicle association of kinesin-1 motor components and activates axonal transport
Araki, Y. et al
EMBO J., ***26***, *1475-1486 (2007)*

Alcadeinα (Alcα) is an evolutionarily conserved type I membrane protein expressed in neurons. We show here that Alcα strongly associates with kinesin light chain ($K_D \approx 4–8 \times 10^{-9}$ M) through a novel tryptophan- and aspartic acid-containing sequence. Alcα can induce kinesin-1 association with vesicles and functions as a novel cargo in axonal anterograde transport. JNK-interacting protein 1 (JIP1), an adaptor protein for kinesin-1, perturbs the transport of Alcα, and the kinesin-1 motor complex dissociates from Alcα-containing vesicles in a JIP1 concentration-dependent manner. Alcα-containing vesicles were transported with a velocity different from that of amyloid β-protein precursor (APP)-containing vesicles, which are transported by the same kinesin-1 motor. Alcα- and APP-containing vesicles comprised mostly separate populations in axons *in vivo*. Interactions of Alcα with kinesin-1 blocked transport of APP-containing vesicles and increased β-amyloid generation. Inappropriate interactions of Alc- and APP-containing vesicles with kinesin-1 may promote aberrant APP metabolism in Alzheimer's disease.

3.893 Accumulation of Mutant Neuroserpin Precedes Development of Clinical Symptoms in Familial Encephalopathy with Neuroserpin Inclusion Bodies
Galliciotti, G. et al
Am. J. Pathol., ***170(4)***, *1305-1313 (2007)*

Intracellular protein deposition due to aggregation caused by conformational alteration is the hallmark of a number of neurodegenerative disorders, including Parkinson's disease, tauopathies, Huntington's disease, and familial encephalopathy with neuroserpin inclusion bodies. The latter is an autosomal dominant disorder caused by point mutations in neuroserpin resulting in its destabilization. Mutant neuroserpin polymerizes and forms intracellular aggregates that eventually lead to neurodegeneration. We generated genetically modified mice expressing the late-onset S49P-Syracuse or the early-onset S52R-Portland mutation of neuroserpin in central nervous system neurons. Mice exhibited morphological, biochemical, and clinical features resembling those found in the human disease. Analysis of brains revealed large intraneuronal inclusions composed exclusively of mutant neuroserpin, accumulating long before the development of clinical symptoms in a time-dependent manner. Clinical symptoms and amount of neuroserpin inclusions correlated with the predicted instability of the protein. The presence of inclusion bodies in subclinical mice indicates that in humans the prevalence of the disease could be higher than anticipated. In addition to shedding light on the pathophysiology of the human disorder, these mice provide an excellent model to study mechanisms of neurodegeneration or establish novel therapies for familial encephalopathy with neuroserpin inclusion bodies and other neurodegenerative diseases with intracellular protein deposition.

3.894 Cytosolic Activation of Cathepsins Mediates Parvovirus H-1-Induced Killing of Cisplatin and TRAIL-Resistant Glioma Cells
Di Piazza, M. et al
J. Virol., ***81(8)***, *4186-4198 (2007)*

Gliomas are often resistant to the induction of apoptotic cell death as a result of the development of survival mechanisms during astrocyte malignant transformation. In particular, the overexpression of Bcl-2-

family members interferes with apoptosis initiation by DNA-damaging agents (e.g., cisplatin) or soluble death ligands (e.g., TRAIL). Using low-passage-number cultures of glioma cells, we have shown that parvovirus H-1 is able to induce death in cells resistant to TRAIL, cisplatin, or both, even when Bcl-2 is overexpressed. Parvovirus H-1 triggers cell death through both the accumulation of lysosomal cathepsins B and L in the cytosol of infected cells and the reduction of the levels of cystatin B and C, two cathepsin inhibitors. The impairment of either of these effects protects glioma cells from the viral lytic effect. In normal human astrocytes, parvovirus H-1 fails to induce a killing mechanism. In vivo, parvovirus H-1 infection of rat glioma cells intracranially implanted into recipient animals triggers cathepsin B activation as well. This report identifies for the first time cellular effectors of the killing activity of parvovirus H-1 against malignant brain cells and opens up a therapeutic approach which circumvents their frequent resistance to other death inducers.

3.895 Knockdown of ACAT-1 reduces amyloidogenic processing of APP
Huttunen, H.J., Greco, C. and Kovacs, D.M.
FEBS Lett., ***581***, *1688-1692 (2007)*

Previous studies have shown that acyl-coenzyme A:cholesterol acyl transferase (ACAT), an enzyme that controls cellular equilibrium between free cholesterol and cholesteryl esters, modulates proteolytic processing of APP in cell-based and animal models of Alzheimer's disease. Here we report that ACAT-1 RNAi reduced cellular ACAT-1 protein by ~50% and cholesteryl ester levels by 22% while causing a slight increase in the free cholesterol content of ER membranes. This correlated with reduced proteolytic processing of APP and 40% decrease in Aβ secretion. These data show that even a modest decrease in ACAT activity can have robust suppressive effects on Aβ generation.

3.896 The Nicastrin-like Protein Nicalin Regulates Assembly and Stability of the Nicalin-Nodal Modulator (NOMO) Membrane Protein Complex
Haffner, C., Dettmer, U., Weiler, T. And Haass, C.
J. Biol. Chem., ***282(14)***, *10632-10638 (2007)*

The assembly of the γ-secretase complex, an Alzheimer disease-related protease required for β-amyloid generation, is tightly regulated and predominantly limited by the stoichiometrical availability of its components. We have identified a novel endoplasmic reticulum-located protein complex that is regulated in a similar fashion. It contains the recently identified Nodal signaling antagonists Nicalin (a distant homolog of the γ-secretase component Nicastrin) and NOMO (Nodal modulator). Using an RNA interference approach, we found that Nicalin and NOMO became unstable in the absence of the respective binding partner, suggesting that complex formation has a stabilizing effect. Overexpression of Nicalin resulted in an increase in NOMO, whereas endogenous Nicalin was reduced below the detection limit. Both effects were shown to occur at a post-transcriptional level. Thus, NOMO is most likely produced in excess amounts and either stabilized by Nicalin or rapidly degraded. In contrast, Nicalin levels are limited independently of NOMO. We, therefore, propose that Nicalin controls the assembly and stability of the Nicalin-NOMO complex.

3.897 Free Cholesterol Alters Lipid Raft Structure and Function Regulating Neutrophil Ca2+ Entry and Respiratory Burst: Correlations with Calcium Channel Raft Trafficking
Kannan, K.B., Barlos, D. and Hauser, C.J.
J. Immunol., ***178***, *5253-5261 (2007)*

Recent studies associate cholesterol excess and atherosclerosis with inflammation. The link between these processes is not understood, but cholesterol is an important component of lipid rafts. Rafts are thought to concentrate membrane signaling molecules and thus regulate cell signaling through G protein-coupled pathways. We used methyl β-cyclodextrin to deplete cholesterol from polymorphonuclear neutrophil (PMN) rafts and thus study the effects of raft disruption on G protein-coupled Ca^{2+} mobilization. Methyl β-cyclodextrin had no effect on Ca^{2+} store depletion by the G protein-coupled agonists platelet-activating factor or fMLP, but abolished agonist-stimulated Ca^{2+} entry. Free cholesterol at very low concentrations regulated Ca^{2+} entry into PMN via nonspecific Ca^{2+} channels in a biphasic fashion. The specificity of cholesterol regulation for Ca^{2+} entry was confirmed using thapsigargin studies. Responses to cholesterol appear physiologic because they regulate respiratory burst in a proportional biphasic fashion. Investigating further, we found that free cholesterol accumulated in PMN lipid raft fractions, promoting formation and polarization of membrane rafts. Finally, the transient receptor potential calcium channel protein TRPC1 redistributed to raft fractions in response to cholesterol. The uniformly biphasic relationships between

cholesterol availability, Ca^{2+} signaling and respiratory burst suggest that Ca^{2+} influx and PMN activation are regulated by the quantitative relationships between cholesterol and other environmental lipid raft components. The association between symptomatic cholesterol excess and inflammation may therefore in part reflect free cholesterol- dependent changes in lipid raft structure that regulate immune cell Ca^{2+} entry. Ca^{2+} entry-dependent responses in other cell types may also reflect cholesterol bioavailability and lipid incorporation into rafts.

3.898 Association of putative ammonium exporters Ato with detergent-resistant compartments of plasma membrane during yeast colony development: pH affects Ato1p localisation in patches
Ricicova, M., Kucerova, H., Vachova, L. and Palkova, Z.
*Biochim. Biophys. Acta, **1768**, 1170-1178 (2007)*

It was proposed that Ato1p, Ato2p and Ato3p have a role in ammonia production by *Saccharomyces cerevisiae* colonies (Palkova et al., Mol Biol Cell 13: 3901–3914, 2002). In this study, we show that all three Ato proteins localise to the plasma membrane and their appearance correlates with the beginning of ammonia release. The expression of *ATO* genes is controlled by ammonia. All three Ato–GFP proteins associate with detergent-resistant membranes; two of them, Ato1p–GFP and Ato3p–GFP, localise to patches visible under the fluorescence microscope. In contrast with Ato3p–GFP which forms stable patches, the formation of those of Ato1p–GFP is pH dependent. Ato1p–GFP patches form at pH above 6 and they disappear at pH 5 or lower. Both changes, Ato1p–GFP clustering and patches spreading are reversible. The Ato1p–GFP spreading at low pH is independent on endocytosis. These data suggest that besides the ammonia induction of Ato protein synthesis, pH may rapidly regulate Ato1p function.

3.899 Polybasic KKR Motif in the Cytoplasmic Tail of Nipah Virus Fusion Protein Modulates Membrane Fusion by Inside-Out Signaling
Aguilar, H et al
*J. Virol., **81(9)**, 4520-4532 (2007)*

The cytoplasmic tails of the envelope proteins from multiple viruses are known to contain determinants that affect their fusogenic capacities. Here we report that specific residues in the cytoplasmic tail of the Nipah virus fusion protein (NiV-F) modulate its fusogenic activity. Truncation of the cytoplasmic tail of NiV-F greatly inhibited cell-cell fusion. Deletion and alanine scan analysis identified a tribasic KKR motif in the membrane-adjacent region as important for modulating cell-cell fusion. The K1A mutation increased fusion 5.5-fold, while the K2A and R3A mutations decreased fusion 3- to 5-fold. These results were corroborated in a reverse-pseudotyped viral entry assay, where receptor-pseudotyped reporter virus was used to infect cells expressing wild-type or mutant NiV envelope glycoproteins. Differential monoclonal antibody binding data indicated that hyper- or hypofusogenic mutations in the KKR motif affected the ectodomain conformation of NiV-F, which in turn resulted in faster or slower six-helix bundle formation, respectively. However, we also present evidence that the hypofusogenic phenotypes of the K2A and R3A mutants were effected via distinct mechanisms. Interestingly, the K2A mutant was also markedly excluded from lipid rafts, where ~20% of wild-type F and the other mutants can be found. Finally, we found a strong negative correlation between the relative fusogenic capacities of these cytoplasmic-tail mutants and the avidities of NiV-F and NiV-G interactions ($P = 0.007$, $r^2 = 0.82$). In toto, our data suggest that inside-out signaling by specific residues in the cytoplasmic tail of NiV-F can modulate its fusogenicity by multiple distinct mechanisms.

3.900 Participation of Rab5, an Early Endosome Protein, in Hepatitis C Virus RNA Replication Machinery
Stone, M., Jia, S., Do Heo, W., Meyer, T. and Konan, K.V.
*J. Virol., **81(9)**, 4551-4563 (2007)*

Like most positive-strand RNA viruses, hepatitis C virus (HCV) is believed to replicate its genome on the surface of rearranged membranes. We have shown previously that HCV NS4AB, but not the product NS4B, inhibits endoplasmic reticulum (ER)-to-Golgi protein traffic (K. V. Konan, T. H. Giddings, Jr., M. Ikeda, K. Li, S. M. Lemon, and K. Kirkegaard, J. Virol. 77:7843-7855). However, both NS4AB and NS4B can induce "membranous web" formation, first reported by Egger et al. (D. B Egger, R. Gosert, L. Bianchi, H. E. Blum, D. Moradpour, and K. Bienz, J. Virol. 76:5974-5984), which is also observed in HCV-infected cells (Y. Rouille, F. Helle, D. Delgrange, P. Roingeard, C. Voisset, E. Blanchard, S. Belouzard, J. McKeating, A. H. Patel, G. Maertens, T. Wakita, C. Wychowski, and J. Dubuisson, J. Virol. 80:2832-2841) and cells that bear a subgenomic NS5A-green fluorescent protein (GFP) replicon (D. Moradpour, M.

J. Evans, R. Gosert, Z. Yuan, H. E. Blum, S. P. Goff, B. D. Lindenbach, and C. M. Rice, J. Virol. 78:7400-7409). To determine the intracellular origin of the web, we examined NS4B colocalization with endogenous cellular markers in the context of the full-length or subgenomic replicon. We found that, in addition to ER markers, early endosome (EE) proteins, including Rab5, were associated with web-inducing protein NS4B. Furthermore, an immunoisolated fraction containing NS4B was found to contain both ER and EE proteins. Using fluorescence microscopy, we showed that wild-type and constitutively active Rab5 proteins were associated with NS4B. Interestingly, expression of dominant-negative Rab5 resulted in significant loss of GFP fluorescence in NS5A-GFP replicon cells. We also found that a small reduction in Rab5 protein expression decreased HCV RNA synthesis significantly. Furthermore, transfection of labeled Rab5 small interfering RNAs into NS5A-GFP replicon cells resulted in a significant decrease in GFP fluorescence. Finally, Rab5 protein was found to coimmunoprecipitate with HCV NS4B. These studies suggest that EE proteins, including Rab5, may play a role in HCV genome replication or web formation.

3.901 ***Measles virus*** **nucleocapsid transport to the plasma membrane requires stable expression and surface accumulation of the viral matrix protein**
Runkler, N., Pohl, C., Schneider-Schaulies, S., Klenk, H-D. and Maisner, A.
Cell. Microbiol., ***9(5)****, 1203-1214 (2007)*

In measles virus (MV)-infected cells the matrix (M) protein plays a key role in virus assembly and budding processes at the plasma membrane because it mediates the contact between the viral surface glycoproteins and the nucleocapsids. By exchanging valine 101, a highly conserved residue among all paramyxoviral M proteins, we generated a recombinant MV (rMV) from cloned cDNA encoding for a M protein with an increased intracellular turnover. The mutant rMV was barely released from the infected cells. This assembly defect was not due to a defective M binding to other matrix- or nucleoproteins, but could rather be assigned to a reduced ability to associate with cellular membranes, and more importantly, to a defective accumulation at the plasma membrane which was accompanied by the deficient transport of nucleocapsids to the cell surface. Thus, we show for the first time that M stability and accumulation at intracellular membranes is a prerequisite for M and nucleocapsid co-transport to the plasma membrane and for subsequent virus assembly and budding processes.

3.902 **Establishment of subcellular fractionation techniques to monitor the intracellular fate of polymer therapeutics II. Identification of endosomal and lysosomal compartments in HepG2 cells combining single-step subcellular fractionation with fluorescent imaging**
Manunta, M., Izzo, L., Duncan, R. and Jones, A.T.
J. Drug. Target., ***15(1)****, 37-50 (2007)*

As they are often designed for lysosomotropic, endosomotropic and/or transcellular delivery, an understanding of intracellular trafficking pathways is essential to enable optimised design of novel polymer therapeutics. Here, we describe a single-step density gradient subcellular fractionation method combined with fluorescent detection analysis that provides a new tool for characterisation of endocytic traffic of polymer therapeutics. Hepatoma (HepG2) cells were used as a model and cell breakage was optimised using a cell cracker to ensure assay of the whole cell population. After removal of unbroken cells and nuclei, the cell lysate as a post-nuclear supernatant (PNS) was layered onto an iodixanol (OptiPrep) density gradient optimised to 5-20%. Early endosomes, late endosomes and lysosomes were identified from gradient fractions by immunoblotting for marker proteins early endosome antigen 1 (EEA 1) and lysosomal associated membrane protein 1 (LAMP 1) using horseradish peroxidase or fluorescently-labelled secondary antibodies. Lysosomes were also detected using N-acetyl-beta-glucosamindase (Hex A) activity. In addition, cells were incubated with Texas-red labelled transferrin (TxR-Tf) for 5 min to specifically label early endosomes and this was directly detected from SDS-PAGE gels. Internalised macromolecules and colloidal particles can potentially alter vesicle buoyant density. To see if typical macromolecules of interest would alter vesicle density or perturb vesicle traffic, HepG2 cells were incubated with dextran or a polyethyleneglycol (PEG)-polyester dendron G4 (1 mg/ml for 24 h). The PEG-polyester dendron G4 caused a slight redistribution of endocytic structures to lower density fractions but immunofluorescence microscopy showed no obvious dendron effects. In conclusion, the combined subcellular fractionation with fluorescent imaging approach described here can be used as a tool for both fundamental cell biology research and/or the quantitative localisation of polymer therapeutics in the endocytic pathway.

3.903 Differential stimulation-induced receptor localization in lipid rafts for interleukin-6 family cytokines signaling through the gp130/leukemia inhibitory factor receptor complex
Port, M.D., Gibson, R.-M. and Nathanson, N.M.
J. Neurochem., ***101***, *782-793 (2007)*

Leukemia inhibitory factor (LIF) and ciliary neurotrophic factor (CNTF) are cytokines which signal through receptor complexes that include the receptor subunits glycoprotein 130 (gp130) and the LIF receptor (LIFR), but CNTF also requires the non-signal transducing CNTF receptor (CNTFR) for binding. We show here that in IMR-32 neuronal cells endogenously expressing the receptor subunits for LIF and CNTF, CNTFR, but not gp130 or LIFR, is found in detergent-resistant lipid rafts. In addition, stimulation of these cells with CNTF resulted in a rapid translocation of a portion of gp130 and LIFR into detergent-resistant lipid rafts while an equivalent stimulation with LIF did not. Disruption of lipid rafts by cholesterol depletion of cell membranes blocked the CNTF-induced translocation of LIFR and gp130. Interestingly, while cholesterol-depletion did not inhibit signal transducer and activator of transcription 3 phosphorylation by either CNTF or LIF stimulation, it strongly inhibited both CNTF- and LIF-mediated phosphorylation of extracellular signal-regulated kinases 1 and 2 and Akt. LIF and CNTF generally appear to have redundant effects in cells responsive to both cytokines. Intriguingly, the data presented here suggest a possible mechanism whereby CNTF or other cytokines that signal through CNTFR could generate signals distinct from those elicited by cytokines such as LIF which utilize a LIFR/gp130 heterodimer, via association with or exclusion from lipid rafts.

3.904 Molecular characterization of GDD1/TMEM16E, the gene product responsible for autosomal dominant gnathodiaphyseal dysplasia
Mizuta, K. et al
Biochem. Biophys. Acta, ***357***, *126-132 (2007)*

The human *GDD1/TMEM16E* gene has been found to be mutated in *gnathodiaphyseal dysplasia*, an unusual skeletal syndrome with autosomal dominant inheritance. The molecular and biochemical function(s) of GDD1 protein has not yet been elucidated. In this study, we examined the murine *GDD1* gene expression pattern during embryonic development, and characterized the cellular and tissue localizations of its gene product using a GDD1-specific antibody. In the developing embryos, *GDD1* mRNA expression was principally associated with differentiating and developing somites, with a highly complex spatiotemporal pattern that involved the myotomal and sclerotomal lineages of somites. Biochemical studies indicated that GDD1 protein is an integral membrane glycoprotein that resides predominantly in intracellular vesicles. Immunohistochemical analysis showed a high level of murine GDD1 protein expression in cardiac and skeletal muscle tissues, and in growth-plate chondrocytes and osteoblasts in bone. These observations suggest diverse cellular role(s) of GDD1 in the development of musculoskeletal system.

3.905 UK114, a YjgF/Yer057p/UK114 family protein highly conserved from bacteria to mammals, is localized in rat liver peroxisomes
Antonenkov, V., Ohlmeier, S., Sormunen, R.T. and Hiltunen, J.K.
Biochem. Biophys. Acta, ***357***, *252-257 (2007)*

Mammalian UK114 belongs to a highly conserved family of proteins with unknown functions. Although it is believed that UK114 is a cytosolic or mitochondrial protein there is no detailed study of its intracellular localization. Using analytical subcellular fractionation, electron microscopic colloidal gold technique, and two-dimensional gel electrophoresis of peroxisomal matrix proteins combined with mass spectrometric analysis we show here that a large portion of UK114 is present in rat liver peroxisomes. The peroxisomal UK114 is a soluble matrix protein and it is not inducible by the peroxisomal proliferator clofibrate. The data predict involvement of UK114 in peroxisomal metabolism.

3.906 Fis1, DLP1, and Pex11p coordinately regulate peroxisome morphogenesis
Kobayashi, S., Tanaka, A. and Fujika, Y.
Exp. Cell Res., ***313***, *1675-1686 (2007)*

Dynamin-like protein 1 (DLP1) and Pex11pβ function in morphogenesis of peroxisomes. In the present work, we investigated whether Fis1 is involved in fission of peroxisomes. Endogenous Fis1 was morphologically detected in peroxisomes as well as mitochondria in wild-type CHO-K1 and *DLP1*-defective ZP121 cells. Subcellular fractionation studies also revealed the presence of Fis1 in peroxisomes.

Peroxisomal Fis1 showed the same topology, i.e., C-tail anchored membrane protein, as the mitochondrial one. Furthermore, ectopic expression of *FIS1* induced peroxisome proliferation in CHO-K1 cells, while the interference of *FIS1* RNA resulted in tubulation of peroxisomes, hence reducing the number of peroxisomes. Fis1 interacted with Pex11pβ, by direct binding apparently involving the C-terminal region of Pex11pβ in the interaction. Pex11pβ also interacted with each other, whereas the binding of Pex11pβ to DLP1 was not detectable. Moreover, ternary complexes comprising Fis1, Pex11pβ, and DLP1 were detected by chemical cross-linking. We also showed that the highly conserved N-terminal domain of Pex11pβ was required for the homo-oligomerization of Pex11pβ and indispensable for the peroxisome-proliferating activity. Taken together, these findings indicate that Fis1 plays important roles in peroxisome division and maintenance of peroxisome morphology in mammalian cells, possibly in a concerted manner with Pex11pβ and DLP1.

3.907 Opposing Actions of Endocannabinoids on Cholangiocarcinoma Growth: RECRUITMENT OF Fas AND Fas LIGAND TO LIPID RAFTS
DeMorrow, S. et al
J. Biol. Chem., ***282(17)***, *13098-13113 (2007)*

Cholangiocarcinomas are devastating cancers of biliary origin with limited treatment options. Modulation of the endocannabinoid system is being targeted to develop possible therapeutic strategies for a number of cancers; therefore, we evaluated the effects of the two major endocannabinoids, anandamide and 2-arachidonylglycerol, on numerous cholangiocarcinoma cell lines. Although anandamide was antiproliferative and proapoptotic, 2-arachidonylglycerol stimulated cholangiocarcinoma cell growth. Specific inhibitors for each of the cannabinoid receptors did not prevent either of these effects nor did pretreatment with pertussis toxin, a $G_{i/o}$ protein inhibitor, suggesting that anandamide and 2-arachidonylglycerol did not exert their diametric effects through any known cannabinoid receptor or through any other $G_{i/o}$ protein-coupled receptor. Using the lipid raft disruptors methyl-β-cyclodextrin and filipin, we demonstrated that anandamide, but not 2-arachidonylglycerol, requires lipid raft-mediated events to inhibit cellular proliferation. Closer inspection of the lipid raft structures within the cell membrane revealed that although anandamide treatment had no observable effect 2-arachidonylglycerol treatment effectively dissipated the lipid raft structures and caused the lipid raft-associated proteins lyn and flotillin-1 to disperse into the surrounding membrane. In addition, anandamide, but not 2-arachidonylglycerol, induced an accumulation of ceramide, which was required for anandamide-induced suppression of cell growth. Finally we demonstrated that anandamide and ceramide treatment of cholangiocarcinoma cells recruited Fas and Fas ligand into the lipid rafts, subsequently activating death receptor pathways. These findings suggest that modulation of the endocannabinoid system may be a target for the development of possible therapeutic strategies for the treatment of this devastating cancer.

3.908 RhoB plays an essential role in CXCR2 sorting decisions
Neel, N.F., Lapierre, L.A., Goldenring, J.R. and Richmond, A.
J. Cell Sci., ***120***, *1559-1571 (2007)*

The CXCR2 chemokine receptor is a G-protein-coupled receptor that undergoes clathrin-mediated endocytosis upon ligand binding. The trafficking of CXCR2 is crucial for cells to maintain a proper chemotactic response. The mechanisms that regulate the recycling/degradation sorting decision are unknown. In this study, we used dominant-negative (T19N) and GTPase-deficient activated (Q63L) RhoB mutants, as well as RhoB small interfering RNA (siRNA) to investigate the role of RhoB in CXCR2 trafficking. Expression of either of the RhoB mutants or transfection of RhoB siRNA impaired CXCR2-mediated chemotaxis. Expression of RhoB T19N and transfection of RhoB siRNA impaired sorting of CXCR2 to the lysosome after 3 hours of CXCL8 stimulation and impaired CXCL8-induced CXCR2 degradation. In cells expressing the RhoB Q63L mutant, CXCR2 recycling through the Rab11a recycling compartment was impaired after 30 minutes of CXCL8 stimulation as was CXCL8-induced CXCR2 degradation. For cells expressing activated RhoB, CXCR2 colocalized with Rab4, a marker for the rapid recycling pathway, and with the mannose-6-phosphate receptor, which traffics between the trans-Golgi network and endosomes. These data suggest that CXCR2 recycles through alternative pathways. We conclude that oscillation of RhoB GTPase activity is essential for appropriate sorting decisions, and for directing CXCR2 degradation and recycling – events that are required for optimal chemotaxis.

3.909 Tyrosine phosphorylation and lipid raft association of pseudorabies virus glycoprotein E during antibody-mediated capping
Desplanques, A.S., Nauwynck, H.J., Tilleman, K., Deforce, D. and Favoreel, H.W.

Virology, ***362(1)***, *60-66 (2007)*

In specific cell types infected with the alphaherpesviruses herpes simplex virus and pseudorabies virus (PRV), addition of virus-specific antibodies results in redistribution of cell-surface-anchored viral proteins. This redistribution is triggered by the viral protein gE and consists of the directional movement of the antibody–antigen complexes to one pole of the cell. This viral capping process has been associated with increased antibody-resistant virus spread and strongly resembles immunoreceptor capping, a process that is crucial in activation of different immune cells (e.g. capping of Fcγ-receptors, B and T cell receptors). Here, we report that the PRV gE-mediated viral capping process results in increased Src kinase-mediated tyrosine phosphorylation of the cytoplasmic domain of gE and that a fraction of gE associates with lipid rafts, all very reminiscent of immunoreceptor capping. These results provide evidence that gE-mediated capping is a viral mimicry of immunoreceptor capping.

3.910 APOBEC3G Multimers Are Recruited to the Plasma Membrane for Packaging into Human Immunodeficiency Virus Type 1 Virus-Like Particles in an RNA-Dependent Process Requiring the NC Basic Linker
Burnett, A. and Spearman, P.
J. Virol., ***81(10)***, *5000-5013 (2007)*

APOBEC3G is an endogenous host restriction factor that inhibits human immunodeficiency virus (HIV) replication. The antiviral activity of APOBEC3G is dependent upon its incorporation into the virus particle. The mechanisms governing incorporation of APOBEC3G into virus particles are not completely understood. In particular, some investigators have reported that APOBEC3G interacts directly with the nucleocapsid (NC) subunit of Gag, while others have found that an RNA intermediate is required for Gag-APOBEC3G interactions. In this study, we confirmed the RNA dependence of APOBEC3G packaging and performed detailed mapping of the determinants within NC that are required for virion incorporation. Surprisingly, APOBEC3G packaging did not correlate well with the presence of the N-terminal "I," or interaction, domain within NC. Specifically, Gag constructs containing only the N-terminal region of NC packaged minimal amounts of APOBEC3G, while significant levels of APOBEC3G packaging were achieved with Gag constructs containing the basic linker region of NC. Furthermore, membrane-binding experiments revealed that the basic linker region was essential for the membrane association of APOBEC3G in a Gag-APOBEC3G complex. Fluorescence resonance energy transfer was detected between labeled APOBEC3G in cells and in particles, indicating that APOBEC3G is packaged as a multimer that is bound to packaged RNA. Regions of APOBEC3G-Gag colocalization at the plasma membrane were detected that were distinct from the punctate cytoplasmic bodies where APOBEC3G accumulates within the cell. Together, our results indicate that APOBEC3G multimerizes in an RNA-dependent fashion and that RNA-APOBEC3G multimers are recruited to the plasma membrane and subsequently into virion particles by Gag.

3.911 The Tyrosine Kinase Fyn Determines the Localization of TrkB Receptors in Lipid Rafts
Pereira, D.R. and Chao, M.V.
J. Neurosci., ***27(18)***, *4859-4869 (2007)*

Localization of Trk neurotrophin receptors is an important factor in directing cellular communication in developing and mature neurons. One potential site of action is in lipid raft membrane microdomains. Although Trk receptors have been localized to lipid rafts, little is known about how these neurotrophin receptors are directed there or how localization to these membrane microdomains regulates Trk signaling. Here, we report that the TrkB brain-derived neurotrophic factor (BDNF) receptor specifically localized to intracellular lipid rafts in cortical and hippocampal membranes in response to BDNF and that this process was critically dependent on the tyrosine kinase Fyn. BDNF-induced TrkB accumulation at lipid rafts was prevented by blocking the internalization of TrkB. BDNF stimulation also resulted in the association between endogenous TrkB and Fyn. Moreover, in neurons derived from Fyn knock-out mice, the translocation of TrkB to lipid rafts in response to BDNF was compromised, whereas the corticohippocampal region of Fyn mutants displayed lower amounts of TrkB in lipid rafts *in vivo*. In support of a role for lipid rafts in neurotrophin signaling, inhibiting TrkB translocation to lipid rafts, either by using Fyn knock-out neurons or lipid raft-disturbing agents, prevented the full activation of TrkB and of downstream phospholipase C-γ. These results indicate that the lipid raft localization of TrkB receptors is regulated by Fyn and represents an important factor in determining the outcome of BDNF signaling in neurons.

3.912 Coupling of the de Novo Fatty Acid Biosynthesis and Lipoylation Pathways in Mammalian Mitochondria

Witkowski, A., Joshi, A. and Smith, S.
J. Biol. Chem., ***282(19)***, *14178-14185 (2007)*

The objective of this study was to identify the products and possible role of a putative pathway for *de novo* fatty acid synthesis in mammalian mitochondria. Bovine heart mitochondrial matrix preparations were prepared free from contamination by proteins from other subcellular components and, using a combination of radioisotopic labeling and mass spectrometry, were shown to contain all of the enzymes required for the extension of a 2-carbon precursor by malonyl moieties to saturated acyl-ACP thioesters containing up to 14 carbon atoms. A major product was octanoyl-ACP and, in the presence of the apo-H-protein of the glycine cleavage complex, the newly synthesized octanoyl moieties were translocated to the lipoylation site on the acceptor protein. These studies demonstrate that one of the functions of the *de novo* fatty acid biosynthetic pathway in mammalian mitochondria is to provide the octanoyl precursor required for the essential protein lipoylation pathway.

3.913 Separation of cell-cell adhesion complexes by differential centrifugation

Vogelmann, R. and Nelson, W.J.
Methods in Mol. Biol., ***370***, *11-22 (2007)*

The number of proteins found associated with cell-cell adhesion substructures is growing rapidly. Based on potential protein-protein interactions, complex protein networks at cell-cell contacts can be modeled. Traditional studies to examine protein-protein interactions include co-immunoprecipitation or pull-down experiments of tagged proteins. These studies provide valuable information that proteins can associate directly or indirectly through other proteins in a complex. However, they do not clarify if a given protein is part of other protein complexes or inform about the specificity of those interactions in the context of adhesion substructures. Thus, it is not clear if models compiled from these types of studies reflect the combination of protein interactions in the adhesion complex in vivo for a specific cell type. Therefore, we present here a method to separate cell-cell contact membrane substructures with their associated protein complexes based on their buoyant behavior in iodixanol density gradients. Analysis of 16 proteins of the apical junctional complex (AJC) in epithelial Madin-Darby canine kidney cells revealed a more simple organization of the AJC adhesion complex than that predicted from the combination of all possible protein-protein interactions defined from co-immunoprecipitation and pull-down experiments.

3.914 HSV Viral Envelope Proteins Partition With Lipid Rafts in Infected Retinal Ganglion Cell Axons

Cortez, D.A., Sucher, A. and LaVail, J.H.
Invest. Ophthalmol. Vis. Sci., ***48***, *E-abstract 3166 (2007)*

Purpose: Herpes simplex virus type 1 (HSV) is responsible for recurrent scarring of the corneal epithelium in ocular herpetic keratitis, a common cause of blindness. HSV envelope glycoproteins are essential for cell-cell spread of infection from trigeminal axons to corneal cells. What has been lacking is details of how newly made envelope proteins are transported within axons. By analogy to the transport of synaptic membrane precursors, lipid raft membranes may also support the transport of viral glycoproteins. We have tested the hypothesis that HSV glycoproteins are transported in association with lipid raft membranes in infected retinal axons in vivo.
Methods: Murine retinal ganglion cells were infected with a wild-type (wt) virus, and after 24 hrs the mice were given Valacyclovir to pulse infect the neurons. The optic pathways were dissected 5 days postinfection, and the tissues were processed for Western blotting using antibodies to gB, gC and gD. Additional animals were infected and treated as above, but the optic pathways were dissected and prepared in an **Optiprep** flotation assay to separate detergent-resistant membranes (DRM) and detergent-soluble membranes (DSM). We used GM1 and caveolin as control proteins for DRM and transferrin receptor as a control for DSM.
Results: By 5 days postinfection all three glycoproteins were transported to the OT. However, the transport of gD appeared to be more efficient than that of gC or gB. In preliminary studies all of the tested glycoproteins, (gB, gC, and gD) as well as GM1 and caveolin were present in the DRM fractions. We also found gB, gC and gD in the DSM fraction. Transferrin receptor was found principally in the DSM fraction.
Conclusions: By five days after infection the three glycoproteins had been transported to the most distal portion of the retinal axons. The three envelope glycoproteins associated with the lipid raft membrane fraction. Further experiments to define host membrane components that associate with transported viral glycoproteins will be essential to understanding the intracellular localization and mechanisms of transport.

3.915 Myelin protein zero/P0 phosphorylation and function require an adaptor protein linking it to RACK1 and PKCα
Gaboreanu, A-M. et al
J. Cell Biol., ***177(4)***, *707-716 (2007)*

Point mutations in the cytoplasmic domain of myelin protein zero (P0; the major myelin protein in the peripheral nervous system) that alter a protein kinase Cα (PKCα) substrate motif (198HRSTK201) or alter serines 199 and/or 204 eliminate P0-mediated adhesion. Mutation in the PKCα substrate motif (R198S) also causes a form of inherited peripheral neuropathy (Charcot Marie Tooth disease [CMT] 1B), indicating that PKCα-mediated phosphorylation of P0 is important for myelination. We have now identified a 65-kD adaptor protein that links P0 with the receptor for activated C kinase 1 (RACK1). The interaction of p65 with P0 maps to residues 179–197 within the cytoplasmic tail of P0. Mutations or deletions that abolish p65 binding reduce P0 phosphorylation and adhesion, which can be rescued by the substitution of serines 199 and 204 with glutamic acid. A mutation in the p65-binding sequence G184R occurs in two families with CMT, and mutation of this residue results in the loss of both p65 binding and adhesion function.

3.916 Characterization of Mammalian Par 6 as a Dual-Location Protein
Cline, E.G. and Nelson, W.J.
Mol. Cell. Biol., ***27(12)***, *4431-4443 (2007)*

Par 6 acts as a scaffold protein to facilitate atypical protein kinase C-mediated phosphorylation of cytoplasmic protein complexes, leading to epithelial and neuronal cell polarization. In addition to its location in the cytoplasm, Par 6 is localized to the nucleus. However, its organization and potential functions in the nucleus have not been examined. Using an affinity-purified Par 6 antibody and a chimera of Par 6 and green fluorescent protein, we show that Par 6 localizes precisely to nuclear speckles, but not to other nuclear structures, and displays characteristics of speckle proteins. We show that Par 6 colocalizes in the nucleus with Tax, a transcriptional activator of the human T-cell leukemia virus type 1 long terminal repeat, but multiple lines of evidence show that Par 6 is not directly involved in known functions of speckle proteins, including general transcription, splicing, or mRNA transport. Significantly, however, the structure of nuclear speckles is lost when Par 6 levels are reduced by Par 6-specific small interfering RNA. Therefore, we hypothesize that Par 6 in the nucleus acts as a scaffolding protein in nuclear speckle complexes, similar to its role in the cytoplasm.

3.917 The Host Protein Staufen1 Participates in Human Immunodeficiency Virus Type 1 Assembly in Live Cells by Influencing pr55Gag Multimerization
Chatel-Chaix, L., Abrahamyan, L., Frechima, C., Mouland, A.J. and DesGroseillers, L.
J. Virol., ***81(12)***, *6216-6230 (2007)*

Human immunodeficiency virus type 1 (HIV-1) requires the sequential activities of virus-encoded proteins during replication. The activities of several host cell proteins and machineries are also critical to the completion of virus assembly and the release of infectious virus particles from cells. One of these proteins, the double-stranded RNA-binding protein Staufen1 (Stau1), selectively associates with the HIV-1 genomic RNA and the viral precursor Gag protein, $pr55^{Gag}$. In this report, we tested whether Stau1 modulates $pr55^{Gag}$ assembly using a new and specific $pr55^{Gag}$ oligomerization assay based on bioluminescence resonance energy transfer (BRET) in both live cells and extracts after cell fractionation. Our results show that both the overexpression and knockdown of Stau1 increase the $pr55^{Gag}$-$pr55^{Gag}$ BRET levels, suggesting a role for Stau1 in regulating $pr55^{Gag}$ oligomerization during assembly. This effect of Stau1 on $pr55^{Gag}$ oligomerization was observed only in membranes, a cellular compartment in which $pr55^{Gag}$ assembly primarily occurs. Consistently, expression of Stau1 harboring a vSrc myristylation signal led to a 6.5-fold enrichment of Stau1 in membranes and a corresponding enhancement in the Stau1-mediated effect on $pr55^{Gag}$-$pr55^{Gag}$ BRET, demonstrating that Stau1 acts on assembly when targeted to membranes. A role for Stau1 in the formation of particles is further supported by the detection of membrane-associated detergent-resistant $pr55^{Gag}$ complexes and the increase of virus-like particle release when Stau1 expression levels are modulated. Our results indicate that Stau1 influences HIV-1 assembly by modulating $pr55^{Gag}$-$pr55^{Gag}$ interactions, as shown in a live cell interaction assay. This likely occurs when Stau1 interacts with membrane-associated assembly intermediates.

3.918 Binding Dynamics of Hepatitis C Virus' NS5A Amphipathic Peptide to Cell and Model Membranes
Cho, N-J., Cheong, K.H., Lee, CH., Frank, C.F. and Glenn, J.S.

J. Virol., ***81(12)***, *6682-6689 (2007)*

Membrane association of the hepatitis C virus NS5A protein is required for viral replication. This association is dependent on an N-terminal amphipathic helix (AH) within NS5A and is restricted to a subset of host cell intracellular membranes. The mechanism underlying this specificity is not known, but it may suggest a novel strategy for developing specific antiviral therapy. Here we have probed the mechanistic details of NS5A AH-mediated binding to both cell-derived and model membranes by use of biochemical membrane flotation and quartz crystal microbalance (QCM) with dissipation. With both assays, we observed AH-mediated binding to model lipid bilayers. When cell-derived membranes were coated on the quartz nanosensor, however, significantly more binding was detected, and the QCM-derived kinetic measurements suggested the existence of an interacting receptor in the target membranes. Biochemical flotation assays performed with trypsin-treated cell-derived membranes exhibited reduced AH-mediated membrane binding, while membrane binding of control cytochrome b5 remained unaffected. Similarly, trypsin treatment of the nanosensor coated with cellular membranes abolished AH peptide binding to the cellular membranes but did not affect the binding of a control lipid-binding peptide. These results therefore suggest that a protein plays a critical role in mediating and stabilizing the binding of NS5A's AH to its target membrane. These results also demonstrate the successful development of a new nanosensor technology ideal both for studying the interaction between a protein and its target membrane and for developing inhibitors of that interaction.

3.919 Membrane microdomain formation is crucial in epiboly during gastrulation of medaka
Adachi, T., Sato, C. and Kitajima, K.
Biochem. Biophys. Res. Comm., ***358(3)***, *848-853 (2007)*

Membrane microdomain (microdomain) was isolated from early gastrula embryos. The isolated microdomain was characterized by enrichment of cholesterol and sphingomyelin, and by the presence of huge glycoproteins containing Lewis X structure. Importance of the microdomain in the progress of epiboly was assessed using methyl β-cyclodextrin (MBCD) and C2-ceramide that disrupt microdomains through different mechanisms. Both reagents efficiently disrupted the microdomain structure and concomitantly impaired epiboly. Interestingly, when embryos pretreated with MBCD, a cholesterol-binding molecule, were exogenously supplemented with cholesterol, the embryos underwent not only reconstitution of the microdomain, but also complete restoration to the normal epiboly. Thus, normal or impaired development is reversibly controlled by the cholesterol-dependent formation or disruption of microdomains. The most typical phenotype of the microdomain-disrupted embryos is detachment of cells from the blastoderm, suggesting that a major contribution of microdomains to epiboly is cell adhesion of blastodermal cells.

3.920 Quantification and regulation of the subcellular distribution of bile acid coenzyme A:amino acid N-acyltransferase activity in rat liver
Styles, N.A., Falany, J.L., Barnes, S. and Falany, C.N.
J. Lipid Res., ***48***, *1305-1315 (2007)*

Bile acid coenzyme A:amino acid N-acyltransferase (BAT) is responsible for the amidation of bile acids with the amino acids glycine and taurine. To quantify total BAT activity in liver subcellular organelles, livers from young adult male and female Sprague-Dawley rats were fractionated into multiple subcellular compartments. In male and female rats, 65–75% of total liver BAT activity was found in the cytosol, 15–17% was found in the peroxisomes, and 5–10% was found in the heavy mitochondrial fraction. After clofibrate treatment, male rats displayed an increase in peroxisomal BAT specific activity and a decrease in cytosolic BAT specific activity, whereas females showed an opposite response. However, there was no overall change in BAT specific activity in whole liver homogenate. Treatment with rosiglitazone or cholestyramine had no effect on BAT activity in any subcellular compartment. These experiments indicate that the majority of BAT activity in the rat liver resides in the cytosol. Approximately 15% of BAT activity is present in the peroxisomal matrix. These data support the novel finding that clofibrate treatment does not directly regulate BAT activity but does alter the subcellular localization of BAT.

3.921 Contact-dependent inhibition of EGFR signaling by Nf2/Merlin
Curto, M., Cole, B.K., Lallemand, D., Liu, C-H. and McClatchey, A.I.
J. Cell Biol., ***177(5)***, *893-903 (2007)*

The neurofibromatosis type 2 (NF2) tumor suppressor, Merlin, is a membrane/cytoskeleton-associated protein that mediates contact-dependent inhibition of proliferation. Here we show that upon cell-cell contact Merlin coordinates the processes of adherens junction stabilization and negative regulation of epidermal growth factor receptor (EGFR) signaling by restraining the EGFR into a membrane compartment from which it can neither signal nor be internalized. In confluent *Nf2*$^{-/-}$ cells, EGFR activation persists, driving continued proliferation that is halted by specific EGFR inhibitors. These studies define a new mechanism of tumor suppression, provide mechanistic insight into the poorly understood phenomenon of contact-dependent inhibition of proliferation, and suggest a therapeutic strategy for *NF2*-mutant tumors.

3.922 Three-dimensional architecture of murine rod outer segments determined by cryoelectron tomography
Nickel, S., Park, P.S-H., Baumeister, W. and Polczewski, K.
J. Cell Biol., ***177(5)***, *917-925 (2007)*

The rod outer segment (ROS) of photoreceptor cells houses all components necessary for phototransduction, a set of biochemical reactions that amplify and propagate a light signal. Theoretical approaches to quantify this process require precise information about the physical boundaries of the ROS. Dimensions of internal structures within the ROS of mammalian species have yet to be determined with the precision required for quantitative considerations. Cryoelectron tomography was utilized to obtain reliable three-dimensional morphological information about this important structure from murine retina. Vitrification of samples permitted imaging of the ROS in a minimally perturbed manner and the preservation of substructures. Tomograms revealed the characteristic highly organized arrangement of disc membranes stacked on top of one another with a surrounding plasma membrane. Distances among the various membrane components of the ROS were measured to define the space available for phototransduction to occur. Reconstruction of segments of the ROS from single-axis tilt series images provided a glimpse into the three-dimensional architecture of this highly differentiated neuron. The reconstructions revealed spacers that likely maintain the proper distance between adjacent discs and between discs and the plasma membrane. Spacers were found distributed throughout the discs, including regions that are distant from the rim region of discs.

3.923 Role of caveolae in the pathogenesis of cholesterol-induced gallbladder muscle hypomotility
Xiao, Z., Schmitz, F., Pricolo, V.E., Biancani, P. and Behar, J.
Am. J. Physiol. Gastrointest. Liver Physiol., ***292***, *G1641-G1649 (2007)*

Muscle cells from human gallbladders (GB) with cholesterol stones (ChS) exhibit a defective contraction, excess cholesterol (Ch) in the plasma membrane, and lower binding of CCK-1 receptors. These abnormalities improved after muscle cells were incubated with Ch-free liposomes that remove the excess Ch from the plasma membrane. The present studies were designed to investigate the role of caveolin-3 proteins (Cav-3) in the pathogenesis of these abnormalities. Muscle cells from GB with ChS exhibit higher Ch levels in the plasma membrane that were mostly localized in caveolae and associated with parallel increases in the expression of Cav-3 in the caveolae compared with that in GB with pigment stones (PS). The overall number of CCK-1 receptors in the plasma membrane was not different between muscle cells from GB with ChS and PS, but they were increased in the caveolae in muscle cells from GB with ChS. Treatment of muscle cells from GB with ChS with a $G\alpha_{i3}$ protein fragment increased the total binding of CCK-1 receptors (from 8.3 to 11.2%) and muscle contraction induced by CCK-8 (from 11.2 to 17.3% shortening). However, $G\alpha_{q/11}$ protein fragment had no such effect. Moreover, neither fragment had any effect on muscle cells from GB with PS. We conclude that the defective contraction of muscle cells with excessive Ch levels in the plasma membrane is due to an increased expression of Cav-3 that results in the sequestration of CCK-1 receptors in the caveolae, probably by inhibiting the functions of $G\alpha_{i3}$ proteins.

3.924 Subcellular Localization and Physiological Significance of Intracellular Mannan-binding Protein
Nonaka, M. et al
J. Biol. Chem., ***282(24)***, *17908-17920 (2007)*

Mannan-binding protein (MBP) is a C-type mammalian lectin specific for mannose and *N*-acetylglucosamine. MBP is mainly synthesized in the liver and occurs naturally in two forms, serum MBP (S-MBP) and intracellular MBP (I-MBP). S-MBP activates complement in association with MBP-associated serine proteases via the lectin pathway. Despite our previous study (Mori, K., Kawasaki, T., and Yamashina, I. (1984) *Arch. Biochem. Biophys.* 232, 223-233), the subcellular localization of I-MBP and its

functional implication have not been clarified yet. Here, as an extension of our previous studies, we have demonstrated that the expression of human MBP cDNA reproduces native MBP differentiation of S-MBP and I-MBP in human hepatoma cells. I-MBP shows distinct accumulation in cytoplasmic granules, and is predominantly localized in the endoplasmic reticulum (ER) and involved in COPII vesicle-mediated ER-to-Golgi transport. However, the subcellular localization of either a mutant (C236S/C244S) I-MBP, which lacks carbohydrate-binding activity, or the wild-type I-MBP in tunicamycin-treated cells shows an equally diffuse cytoplasmic distribution, suggesting that the unique accumulation of I-MBP in the ER and COPII vesicles is mediated by an *N*-glycan-lectin interaction. Furthermore, the binding of I-MBP with glycoprotein intermediates occurs in the ER, which is carbohydrate- and pH-dependent, and is affected by glucose-trimmed high-mannose-type oligosaccharides. These results strongly indicate that I-MBP may function as a cargo transport lectin facilitating ER-to-Golgi traffic in glycoprotein quality control.

3.925 Stepwise proteolysis liberates tau fragments that nucleate the Alzheimer-like aggregation of full-length tau in a neuronal cell model
Wang, Y.P., Biernat, J., Pickjardt, M., Mandelkow, E. Amd Mandelkow, E-M.
*PNAS, **104(24)**, 10252-10257 (2007)*

Tau is a highly soluble protein, yet it aggregates abnormally in Alzheimer's disease. Here, we address the question of proteolytic processing of tau and the nucleation of aggregates by tau fragments. We show in neuronal cell models that fragments of the repeat domain of tau containing mutations of FTDP17 (frontotemporal dementia with parkinsonism linked to chromosome 17), produced by endogenous proteases, can induce the aggregation of full-length tau. Fragments are generated by successive cleavages, first N-terminally between K257 and S258, then C-terminally around residues 353–364; conversely, when the N-terminal cleavage is inhibited, no fragmentation and aggregation takes place. The C-terminal truncation and the coaggregation of fragments with full-length tau depends on the propensity for β-structure. The aggregation is modulated by phosphorylation but does not depend on it. Aggregation but not fragmentation as such is toxic to cells; conversely, toxicity can be prevented by inhibiting either aggregation or proteolysis. The results reveal a novel pathway of abnormal tau aggregation in neuronal cells.

3.926 Lipid Rafts Are Triage Centers for Multimeric and Monomeric Thyrotropin Receptor Regulation
Latif, R., Ando, T. and Davies, T.F.
*Endocrinology, **148(7)**, 3164-3175 (2007)*

The TSH receptor (TSHR), a heptahelical G protein-coupled receptor on the surface of thyrocytes, is a major autoantigen and physiological regulator of the thyroid gland. Unlike other G protein-coupled receptors, the TSHR undergoes posttranslational cleavage of its ectodomain, leading to the existence of several forms of the receptor on the plasma membrane. We previously hypothesized that to achieve high fidelity and specificity of TSH ligand or TSHR autoantibody signaling, the TSHR may compartmentalize into microdomains within the plasma membrane. In support of this hypothesis we have shown previously that TSHRs reside in GM_1 ganglioside-enriched lipid rafts in the plasma membrane of TSHR-expressing cells. In this study, we further explored the different forms of TSHRs that reside in lipid rafts. We studied both TSHR-transfected cells and rat thyrocytes, using both nondetergent biochemical analyses and receptor-lipid raft colocalization. Using the biochemical approach, we observed that monomeric receptors existed in both raft and nonraft fractions of the cell surface in the steady state. We also demonstrated that the multimeric forms of the receptor were preferentially partitioned into the lipid microdomains. Different TSHR forms, including multimers, were dynamically regulated both by receptor-specific and postreceptor-specific modulators. TSH ligand and TSHR antibody of the stimulating variety induced a decrease of multimeric forms in the raft fractions. In addition, multimeric and monomeric forms of the receptor were both associated with $G_{s\alpha}$ within and without the rafts. Although failure to achieve total lipid raft disruption prevented a conclusion regarding the relative power of TSHR signaling within and without the raft domains, these data showed clearly that not only were a significant proportion of TSHRs residing within lipid microdomains but that constitutive multimerization of TSHRs was actually regulated within the lipid rafts.

3.927 Correlation of Golgi localization of ZW10 and centrosomal accumulation of dynactin
Arasaki, K., Uemura, T., Tani, K. and Tagaya, M.
*Biochem. Biophys. Res. Comm., **359(3)**, 811-816 (2007)*

ZW10 participates in the termination of the spindle checkpoint during mitosis by interacting with dynamitin, a subunit of the dynein accessory complex dynactin. We previously showed that ZW10 is attached to the endoplasmic reticulum through RINT-1 in interphase HeLa cells and involved in membrane transport between the endoplasmic reticulum and Golgi. Although a recent study demonstrated that ZW10 is localized in the Golgi in COS7 cells, the mechanism that regulates ZW10 localization remains unknown. In this study we showed a correlation between the Golgi localization of ZW10 and the centrosomal accumulation of dynactin. The amounts of ZW10 associated with dynactin were larger in cells where ZW10 was present in the Golgi than those where ZW10 was not in the Golgi. The targeting of ZW10 to the perinuclear Golgi region was found to depend on the perinuclear accumulation of dynactin, suggesting that dynactin regulates ZW10 localization.

3.928 Siva is an apoptosis-selective p53 target gene important for neuronal cell death
Jacobs, S.B.R., Basak, S., Murray, J., Pathak, N. and Attardi, L.D.
*Cell Death and Differentiation, **14**, 1374-1385 (2007)*

p53 plays a central role in neuronal cell death resulting from acute injury or disease. To define the pathway by which p53 triggers apoptosis, we used microarray analysis to identify p53 target genes specifically upregulated during apoptosis but not cell cycle arrest. This analysis identified a small subset of targets highly selective for the p53 apoptotic response, including Siva, a proapoptotic protein whose function is not well understood. *Siva*'s expression pattern suggests that it plays an instructive role in apoptosis, and accordingly, we demonstrate that Siva is essential for p53-dependent apoptosis in cerebellar granule neurons. In addition, we determine that endogenous Siva is associated with the plasma membrane and that Caspase-8 and Bid are important for neuronal apoptosis. Our studies highlight the participation of membrane signaling events in p53's apoptotic program in primary neurons and have significant implications for understanding the mechanisms underlying pathogenesis after neuronal injury and in neurodegenerative diseases.

3.929 Identification of an ADAM2-ADAM3 Complex on the Surface of Mouse Testicular Germ Cells and Cauda Epididymal Sperm
Nishimura, H., Myles, D.G. and Primakoff, P.
*J. Biol. Chem., **282(24)**, 17900-17907 (2007)*

Male mice lacking ADAM2 (fertilin β) or ADAM3 (cyritestin) are infertile; cauda epididymal sperm (mature sperm) from these mutant mice cannot bind to the egg zona pellucida. ADAM3 is barely present in *Adam2*-null sperm, despite normal levels of this protein in *Adam2*-null testicular germ cells (TGCs; sperm precursor cells). Here, we have explored the molecular basis for the loss of ADAM3 in *Adam2*-null TGCs to clarify the biosynthetic and functional linkage of ADAM2 and ADAM3. A small portion of total ADAM3 was found present on the surface of wild-type and *Adam2*$^{-/-}$ TGCs at similar levels. In the *Adam2*-null TGCs, however, surface-localized ADAM3 exhibited an increased amount of an endoglycosidase H-resistant form that may be related to instability of ADAM3. Moreover, we found a complex between ADAM2 and ADAM3 on the surface of TGCs and sperm. The intracellular chaperone calnexin was a component of the testicular ADAM2-ADAM3 complex. Our findings suggest that the association with ADAM2 is a key element for stability of ADAM3 in epididymal sperm. The presence of the ADAM2-ADAM3 complex in sperm also suggests a potential role of ADAM2 with ADAM3 in sperm binding to the egg zona pellucida.

3.930 Productive Human Immunodeficiency Virus Type 1 Assembly Takes Place at the Plasma Membrane
Finzi, A., Orthwein, A., Mercier, J. and Cohen, E.A.
*J. Virol., **81(14)**, 7476-7490 (2007)*

Gag proteins are necessary and sufficient to direct human immunodeficiency virus type 1 (HIV-1) particle assembly and budding. Recent evidence suggests that Gag targeting to late endosomal/multivesicular body (LE/MVB) compartments occurs prior to viral particle budding at the plasma membrane (PM). However, the route that Gag follows before reaching its steady-state destinations still remains a subject of debate. Using a subcellular fractionation method that separates PM from LE/MVB combined with pulse-chase labeling, we analyzed Gag trafficking in HIV-1-producing HEK 293T cells. Our results reveal that the majority of newly synthesized Gag is primarily targeted to the PM. While PM-targeted Gag was efficiently released, a significant fraction of the remaining cell surface-associated Gag was found to be subsequently internalized to LE/MVB, where it accumulated, thus accounting for the majority of LE/MVB-associated Gag. Importantly, this accumulation of Gag in LE/MVB was found to be cholesterol dependent since it was

sensitive to the sterol-binding drugs filipin and methyl-ß-cyclodextrin. These results point towards the PM as being the primary site of productive HIV-1 assembly in cells that also support Gag accumulation in intracellular compartments.

3.931 Pitfalls in isolating lipid rafts
Nothdurfter, C., Rammes, G., Rein, T. and Rupprecht, R.
Nature review Neurosci., 8 567 (2007)

The recent Review by Allen *et al*. on lipid raft microdomains and neurotransmitter receptor signalling[1] provides an excellent overview of important structural and functional aspects of these specific membrane microdomains, with a particular focus on their role in the nervous system. Nevertheless, we would like to emphasize two important aspects. As outlined in the Review, the valid and reproducible isolation of lipid rafts is not trivial, but mandatory to draw correct conclusions. Inconsistencies in raft isolation procedures, for example the type, amount and duration of detergent use, make results difficult to compare and may contribute to some controversies in the field. A particularly important issue is the presentation of both a positive and a negative control. Mostly, caveolin 1 or flotillin 1 are used as raft marker proteins[2, 3, 4], whereas the transferrin receptor or other proteins such as the Na^+/K^+-ATPase are reported as non-raft proteins[5, 6, 7]. Only a few studies show convincing data of a clear separation of raft from non-raft proteins[5, 6, 8]. This separation relies highly on the preparation procedure, in particular the use of detergent, for which the type of detergent, the concentration and the duration of incubation are the main determinants. Furthermore, the preparation procedure should be chosen according to the type of tissue under investigation. An example from our laboratory, in which we isolated caveolin 1 and flotillin 1 as raft-associated proteins and the transferrin receptor as a non-raft protein, illustrates this need to vary conditions for different tissue types (Fig. 1). When investigating the concentration of detergent and incubation time needed to separate raft from non-raft proteins within the range reported in the literature[5, 6], we also observed a dose–response relationship[8]. Future studies should therefore clearly demonstrate that the method selected is appropriate for the tissue type under investigation to separate raft from non-raft proteins when claiming raft association of particular proteins.

3.932 Caspase-8 and c-FLIPL Associate in Lipid Rafts with NF-κB Adaptors during T Cell Activation
Misra, R.S. et al
J. Biol. Chem., ***282(27)***, *19365-19374 (2007)*

Humans and mice lacking functional caspase-8 in T cells manifest a profound immunodeficiency syndrome due to defective T cell antigen receptor (TCR)-induced NF-κB signaling and proliferation. It is unknown how caspase-8 is activated following T cell stimulation, and what is the caspase-8 substrate(s) that is necessary to initiate T cell cycling. We observe that following TCR ligation, a small portion of total cellular caspase-8 and c-$FLIP_L$ rapidly migrate to lipid rafts where they associate in an active caspase complex. Activation of caspase-8 in lipid rafts is followed by rapid cleavage of c-$FLIP_L$ at a known caspase-8 cleavage site. The active caspase·c-FLIP complex forms in the absence of Fas (CD95/APO1) and associates with the NF-κB signaling molecules RIP1, TRAF2, and TRAF6, as well as upstream NF-κB regulators PKCθ, CARMA1, Bcl-10, and MALT1, which connect to the TCR. The lack of caspase-8 results in the absence of MALT1 and Bcl-10 in the active caspase complex. Consistent with this observation, inhibition of caspase activity attenuates NF-κB activation. The current findings define a link among TCR, caspases, and the NF-κB pathway that occurs in a sequestered lipid raft environment in T cells.

3.933 Lack of a role of membrane-protein interactions in flow-dependent activation of EnaC
Carattino, M.D., Lin, W., Hill, W.G., Satlin, L.M. and Kleyman, T.R.
Am. J. Physiol. Renal Physiol., ***293,*** *F316-F324 (2007)*

Rates of Na^+ absorption in the distal nephron increase proportionally with the rates of tubular flow. We tested the hypothesis that the deformation or tension generated in the plasma membrane in response to flow activates the epithelial sodium channel (ENaC). We modified the physical properties of the membrane by changing the temperature and the content of cholesterol. Rates of net Na^+ absorption measured in cortical collecting ducts (CCDs) perfused at room temperature at slow (~1) and fast (~5 $nl \cdot min^{-1} \cdot mm^{-1}$) flow rates were less than those measured at 37°C at the same flow rates, although increases in tubular fluid flow rates led to comparable relative increases in net Na^+ absorption at both temperatures. *Xenopus laevis* oocytes expressing ENaC responded to an increase in shear stress at 22–25°C with a discrete delay followed by a monoexponential increase in whole-cell Na^+ currents. We observed that temperature affected *1*) basal

currents, *2*) delay times, *3*) kinetics of activation, and *4*) fold-increase in macroscopic currents in response to flow. The magnitude of the response to flow displayed biphasic behavior as a function of temperature, with a minimal value at 25°C. Steady-state fluorescence anisotropic measurements of purified plasma membranes did not show any obvious phase transition behavior over a temperature range from 8.3°C to 36.5°C. Modification of the content of membrane cholesterol did not affect the response to flow. Our results suggest that the flow-dependent activation of ENaC is not influenced by modifications in the intrinsic properties of the plasma membrane.

3.934 Ceramide transfer protein function is essential for normal oxidative stress response and lifespan
Rao, R.P. et al
*PNAS, **104(27)**, 11364-11369 (2007)*

Ceramide transfer protein (CERT) transfers ceramide from the endoplasmic reticulum to the Golgi complex, a process critical in synthesis and maintenance of normal levels of sphingolipids in mammalian cells. However, how its function is integrated into development and physiology of the animal is less clear. Here, we report the *in vivo* consequences of loss of functional CERT protein. We generated *Drosophila melanogaster* mutant flies lacking a functional CERT (Dcert) protein using chemical mutagenesis and a Western blot-based genetic screen. The mutant flies die early between days 10 and 30, whereas controls lived between 75 and 90 days. They display >70% decrease in ceramide phosphoethanolamine (the sphingomyelin analog in *Drosophila*) and ceramide. These changes resulted in increased plasma membrane fluidity that renders them susceptible to reactive oxygen species and results in enhanced oxidative damage to cellular proteins. Consequently, the flies showed reduced thermal tolerance that was exacerbated with aging and metabolic compromise such as decreasing ATP and increasing glucose levels, reminiscent of premature aging. Our studies demonstrate that maintenance of physiological levels of ceramide phosphoethanolamine by CERT *in vivo* is required to prevent oxidative damages to cellular components that are critical for viability and normal lifespan of the animal.

3.935 Regulatory Binding Partners and Complexes of NHE3
Donowitz, M. and Li, X.
*Physiol. Rev., **87**, 825-972 (2007)*

NHE3 is the brush-border (BB) Na^+/H^+ exchanger of small intestine, colon, and renal proximal tubule which is involved in large amounts of neutral Na^+ absorption. NHE3 is a highly regulated transporter, being both stimulated and inhibited by signaling that mimics the postprandial state. It also undergoes downregulation in diarrheal diseases as well as changes in renal disorders. For this regulation, NHE3 exists in large, multiprotein complexes in which it associates with at least nine other proteins. This review deals with short-term regulation of NHE3 and the identity and function of its recognized interacting partners and the multiprotein complexes in which NHE3 functions.

3.936 Filamin-A regulates actin-dependent clustering of HIV receptors
Jimenez-Baranda, S. et al
*Nature Cell Biol., **9(7)**, 838-846 (2007)*

Human immunodeficiency virus (HIV)-1 infection requires envelope (Env) glycoprotein gp120-induced clustering of CD4 and coreceptors (CCR5 or CXCR4) on the cell surface; this enables Env gp41 activation and formation of a complex that mediates fusion between Env-containing and target-cell membranes1. Kinetic studies show that viral receptors are actively transported to the Env-receptor interface in a process that depends on plasma membrane composition and the actin cytoskeleton2, 3, 4, 5, 6, 7. The mechanisms by which HIV-1 induces F-actin rearrangement in the target cell remain largely unknown. Here, we show that CD4 and the coreceptors interact with the actin-binding protein filamin-A, whose binding to HIV-1 receptors regulates their clustering on the cell surface. We found that gp120 binding to cell receptors induces transient cofilin-phosphorylation inactivation through a RhoA–ROCK-dependent mechanism. Blockade of filamin-A interaction with CD4 and/or coreceptors inhibits gp120-induced RhoA activation and cofilin inactivation. Our results thus identify filamin-A as an adaptor protein that links HIV-1 receptors to the actin cytoskeleton remodelling machinery, which may facilitate virus infection.

3.937 Cholesterol depletion alters detergent-specific solubility profiles of selected tight junction proteins and the phosphorylation of occluding
Lynch, R.D. et al

Exp. Cell Res., ***313(2)***, *2597-2610 (2007)*

Differential centrifugation of Triton X-100 or CHAPS lysates from control and cholesterol (CH)-depleted MDCK II cells, segregated integral tight junction (TJ) proteins associated with detergent-resistant membranes (DRMs) into two groups. Group A proteins (occludin, claudin-2 and -3) were detected in large, intermediate and small aggregates in both detergents, whereas group B proteins (claudin-1, -4 and -7) were observed in small aggregates in TX-100 and in intermediate and small aggregates in CHAPS. Depletion of CH altered the distribution of group A and B proteins among the three size categories in a detergent-specific manner. In lysates produced with octyl glucoside, a detergent that selectively extracts proteins from DRMs, group A proteins were undetectable in large aggregates and CH depletion did not alter the distribution of either group A or B proteins in intermediate or small aggregates. Neither occludin (group A) nor claudin-1 (group B) was in intimate enough contact with CH to be cross-linked to [^{3}H]-photo-cholesterol. However, antibodies to either TJ protein co-immunoprecipitated caveolin-1, a CH-binding protein. Unlike claudins, occludin's presence in TJs and DRMs did not require palmitoylation. Equilibrium density centrifugation on discontinuous OptiPrep gradients revealed detergent-related differences in the densities of TJ-bearing DRMs. There was little or no change in those densities after CH depletion. Removing CH from the plasma membrane increased tyrosine and threonine phosphorylation of occludin, and transepithelial electrical resistance (TER) within 30 min. After 2 h of CH efflux, phospho-occludin levels and TER fell below control values. We conclude that the association of integral TJ proteins with DRMS, pelleted at low speeds, is partially CH-dependent. However, the buoyant density of TJ-associated DRMs is a function of the detergent used and is insensitive to decreases in CH.

3.938

3.939 **The Pseudomonas aeruginosa Secreted Protein PA2934 Decreases Apical Membrane Expression of the Cystic Fibrosis Transmembrane Conductance Regulator**
MacEachran, D.P. et al
Infect. Immun., ***75(8)***, *3902-3912 (2007)*

We previously reported that *Pseudomonas aeruginosa* PA14 secretes a protein that can reduce the apical membrane expression of the *c*ystic *f*ibrosis *t*ransmembrane conductance *r*egulator (CFTR) protein. Here we report that we have used a proteomic approach to identify this secreted protein as PA2394, and we have named the gene *cif*, for *C*FTR *i*nhibitory *f*actor. We demonstrate that Cif is a secreted protein and is found associated with outer membrane-derived vesicles. Expression of Cif in *Escherichia coli* and purification of the C-terminal six-His-tagged Cif protein showed that Cif is necessary and sufficient to mediate the reduction in apical membrane expression of CFTR and a concomitant reduction in CFTR-mediated Cl^- ion secretion. Cif demonstrates epoxide hydrolase activity in vitro and requires a highly conserved histidine residue identified in α/ß hydrolase family enzymes to catalyze this reaction. Mutating this histidine residue also abolishes the ability of Cif to reduce apical membrane CFTR expression. Finally, we demonstrate that the *cif* gene is expressed in the cystic fibrosis (CF) lung and that nonmucoid isolates of *P. aeruginosa* show greater expression of the gene than do mucoid isolates. We propose a model in which the Cif-mediated decrease in apical membrane expression of CFTR by environmental isolates of *P. aeruginosa* facilitates the colonization of the CF lung by this microbe.

3.940 **Caveolin-associated Accumulation of Globotriaosylceramide in the Vascular Endothelium of α-Galactosidase A Null Mice**
Shu, L. and Shayman, J.A.
J. Biol. Chem., ***282(29)***, *20960-20967 (2007)*

Cardiovascular complications, including stroke and myocardial infarction, result in premature mortality in patients with Fabry disease, an X-linked deficiency of α-galactosidase A (α-Gal A). The enzymatic defect results in the deposition of globotriaosylceramide (Gb3) in the vascular endothelium. To better understand the underlying pathogenesis of Fabry disease, the caveolar lipid content of primary cultured mouse aortic endothelial cells isolated from α-Gal A null mice was measured. Lipid mass analysis revealed that the excessive Gb3 in cultured α-*Gal A*-deficient mouse aortic endothelial cells accumulated in endothelial plasma membrane caveolar fractions. The levels of glucosylceramide and lactosylceramide increased in parallel with Gb3 levels in an age-dependent manner, whereas globotetraosylceramide (Gb4) levels reached maximal levels by 6 months of age and then rapidly decreased at older ages. The levels of

cholesterol enriched in caveolar membranes declined in parallel with the progressive deposition of Gb3. Depleting Gb3 with recombinant human α-Gal A protein or D-*threo*-ethylenedioxyphenyl-P4, an inhibitor of glucosylceramide synthase, restored cholesterol in cultured α-Gal A-deficient mouse aortic endothelial cell caveolae. By contrast, recombinant human α-Gal A was less effective in normalizing the cholesterol content. These results demonstrate the caveolar accumulation of glycosphingolipids in an *in vitro* model of a lysosomal storage disease and raise the possibility that dynamic changes in the composition of plasma membrane lipid microdomains may mediate the endothelial dysfunction seen in Fabry disease.

3.941 Lipid Rafts Establish Calcium Waves in Hepatocytes
Nagata, J. et al
*Gastroenterology, **133(1)**, 256-267 (2007)*

Background & Aims: Polarity is critical for hepatocyte function. Ca^{2+} waves are polarized in hepatocytes because the inositol 1,4,5-trisphosphate receptor (InsP3R) is concentrated in the pericanalicular region, but the basis for this localization is unknown. We examined whether pericanalicular localization of the InsP3R and its action to trigger Ca^{2+} waves depends on lipid rafts. Methods: Experiments were performed using isolated rat hepatocyte couplets and pancreatic acini, plus SkHep1 cells as nonpolarized controls. The cholesterol depleting agent methyl-beta-cyclodextrin (mβCD) was used to disrupt lipid rafts. InsP3R isoforms were examined by immunoblot and immunofluorescence. Ca^{2+} waves were examined by confocal microscopy. *Results:* Type II InsP3Rs initially were localized to only some endoplasmic reticulum fractions in hepatocytes, but redistributed into all fractions in mβCD-treated cells. This InsP3R isoform was concentrated in the pericanalicular region, but redistributed throughout the cell after mβCD treatment. Vasopressin-induced Ca^{2+} signals began as apical-to-basal Ca^{2+} waves, and mβCD slowed the wave speed and prolonged the rise time. MβCD had a similar effect on Ca^{2+} waves in acinar cells but did not affect Ca^{2+} signals in SkHep1 cells, suggesting that cholesterol depletion has similar effects among polarized epithelia, but this is not a nonspecific effect of mβCD. *Conclusions:* Lipid rafts are responsible for the pericanalicular accumulation of InsP3R in hepatocytes, and for the polarized Ca^{2+} waves that result. Signaling microdomains exist not only in the plasma membrane, but also in the nearby endoplasmic reticulum, which in turn, helps establish and maintain structural and functional polarity.

3.942 Alzheimer's presenilin 1 modulates sorting of APP and its carboxyl-terminal fragments in cerebral neurons in vivo
Gandy, S. et al
*J. Neurochem., **102**, 619-626 (2007)*

Studies in continuously cultured cells have established that familial Alzheimer's disease (FAD) mutant presenilin 1 (PS1) delays exit of the amyloid precursor protein (APP) from the *trans*-Golgi network (TGN). Here we report the first description of PS1-regulated APP trafficking in cerebral neurons in culture and *in vivo*. Using neurons from transgenic mice or a cell-free APP transport vesicle biogenesis system derived from the TGN of those neurons, we demonstrated that knocking-in an FAD-associated mutant PS1 transgene was associated with delayed kinetics of APP arrival at the cell surface. Apparently, this delay was at least partially attributable to impaired exit of APP from the TGN, which was documented in the cell-free APP transport vesicle biogenesis assay. To extend the study to APP and carboxyl terminal fragment (CTF) trafficking to cerebral neurons *in vivo*, we performed subcellular fractionation of brains from APP transgenic mice, some of which carried a second transgene encoding an FAD-associated mutant form of PS1. The presence of the FAD mutant PS1 was associated with a slight shift in the subcellular localization of both holoAPP and APP CTFs toward iodixanol density gradient fractions that were enriched in a marker for the TGN. In a parallel set of experiments, we used an APP : furin chimeric protein strategy to test the effect of artificially forcing TGN concentration of an APP : furin chimera that could be a substrate for β- and γ-cleavage. This chimeric substrate generated excess Aβ42 when compared with wildtype APP. These data indicate that the presence of an FAD-associated mutant human PS1 transgene is associated with redistribution of the APP and APP CTFs in brain neurons toward TGN-enriched fractions. The chimera experiment suggests that TGN-enrichment of a β-/γ-secretase substrate may play an integral role in the action of mutant PS1 to elevate brain levels of Aβ42.

3.943 Probing the Membrane Environment of the TOR Kinases Reveals Functional Interactions between TORC1, Actin, and Membrane Trafficking in Saccharomyces cerevisiae
Aronova, S., wedaman, K., Anderson, S., Yates III, J. and Powers, T.
*Mol. Biol. Cell, **18**, 2779-2794 (2007)*

The TOR kinases are regulators of growth in eukaryotic cells that assemble into two distinct protein complexes, TORC1 and TORC2, where TORC1 is inhibited by the antibiotic rapamycin. Present models favor a view wherein TORC1 regulates cell mass accumulation, and TORC2 regulates spatial aspects of growth, including organization of the actin cytoskeleton. Here, we demonstrate that in yeast both TORC1 and TORC2 fractionate with a novel form of detergent-resistant membranes that are distinct from detergent-resistant plasma membrane "rafts." Proteomic analysis of these TOR-associated membranes revealed the presence of regulators of endocytosis and the actin cytoskeleton. Genetic analyses revealed a significant number of interactions between these components and TORC1, demonstrating a functional link between TORC1 and actin/endocytosis-related genes. Moreover, we found that inhibition of TORC1 by rapamycin 1) disrupted actin polarization, 2) delayed actin repolarization after glucose starvation, and 3) delayed accumulation of lucifer yellow within the vacuole. By combining our genetic results with database mining, we constructed a map of interactions that led to the identification of additional genetic interactions between TORC1 and components involved in membrane trafficking. Together, these results reveal the broad scope of cellular processes influenced by TORC1, and they underscore the functional overlap between TORC1 and TORC2.

3.944 Evidence for Coupled Biogenesis of Yeast Gap1 Permease and Sphingolipids: Essential Role in Transport Activity and Normal Control by Ubiquitination
Lauwers, E., Grossmann, G. and Andre, B.
*Mol. Biol. Cell, **18**, 3068-3080 (2007)*

Current models for plasma membrane organization integrate the emerging concepts that membrane proteins tightly associate with surrounding lipids and that biogenesis of surface proteins and lipids may be coupled. We show here that the yeast general amino acid permease Gap1 synthesized in the absence of sphingolipid (SL) biosynthesis is delivered to the cell surface but undergoes rapid and unregulated down-regulation. Furthermore, the permease produced under these conditions but blocked at the cell surface is inactive, soluble in detergent, and more sensitive to proteases. We also show that SL biogenesis is crucial during Gap1 production and secretion but that it is dispensable once Gap1 has reached the plasma membrane. Moreover, the defects displayed by cell surface Gap1 neosynthesized in the absence of SL biosynthesis are not compensated by subsequent restoration of SL production. Finally, we show that down-regulation of Gap1 caused by lack of SL biogenesis involves the ubiquitination of the protein on lysines normally not accessible to ubiquitination and close to the membrane. We propose that coupled biogenesis of Gap1 and SLs would create an SL microenvironment essential to the normal conformation, function, and control of ubiquitination of the permease.

3.945 Naked2 Acts as a Cargo Recognition and Targeting Protein to Ensure Proper Delivery and Fusion of TGF-α–containing Exocytic Vesicles at the Lower Lateral Membrane of Polarized MDCK Cells
Li, C. et al
*Mol. Biol. Cell, **18**, 3081-3093 (2007)*

Transforming growth factor-α (TGF-α) is the major autocrine EGF receptor ligand in vivo. In polarized epithelial cells, proTGF-α is synthesized and then delivered to the basolateral cell surface. We previously reported that Naked2 interacts with basolateral sorting determinants in the cytoplasmic tail of a Golgi-processed form of TGF-α and that TGF-α is not detected at the basolateral surface of Madin-Darby canine kidney (MDCK) cells expressing myristoylation-deficient (G2A) Naked2. By high-resolution microscopy, we now show that wild-type, but not G2A, Naked2-associated vesicles fuse at the plasma membrane. We further demonstrate that Naked2-associated vesicles are delivered to the lower lateral membrane of polarized MDCK cells independent of μ1B adaptin. We identify a basolateral targeting segment within Naked2; residues 1-173 redirect NHERF-1 from the apical cytoplasm to the basolateral membrane, and internal deletion of residues 37-104 results in apical mislocalization of Naked2 and TGF-α. Short hairpin RNA knockdown of Naked2 leads to a dramatic reduction in the 16-kDa cell surface isoform of TGF-α and increased cytosolic TGF-α immunoreactivity. We propose that Naked2 acts as a cargo recognition and targeting (CaRT) protein to ensure proper delivery, tethering, and fusion of TGF-α–containing vesicles to a distinct region at the basolateral surface of polarized epithelial cells.

3.946 Characterization of the Properties and Trafficking of an Anchorless Form of the Prion Protein
Campana, V. et al
*J. Biol. Chem., **282(31)**, 22747-22756 (2007)*

Conversion of PrP^{C} into PrP^{Sc} is the central event in the pathogenesis of transmissible prion diseases. Although the molecular basis of this event and the intracellular compartment where it occurs are not yet understood, the association of PrP with cellular membranes and in particular its presence in detergent-resistant microdomains appears to be of critical importance. In addition it appears that scrapie conversion requires membrane-bound glycosylphosphatidylinositol (GPI)-linked PrP. The GPI anchor may affect either the conformation, the intracellular localization, or the association of the prion protein with specific membrane domains. However, how this occurs is not known. To understand the relevance of the GPI anchor for the cellular behavior of PrP, we have studied the biosynthesis and localization of a PrP version which lacks the GPI anchor attachment signal (PrPΔGPI). We found that PrPΔGPI is tethered to cell membranes and associates to membrane detergent-resistant microdomains but does not assume a transmembrane topology. Differently to PrP^{C}, this protein does not localize at the cell surface but is mainly released in the culture media in a fully glycosylated soluble form. The cellular behavior of anchorless PrP explains why PrPΔGPI Tg mice can be infected but do not show the classical signs of the disorder, thus indicating that the plasma membrane localization of PrP^{C} and/or of the converted scrapie form might be necessary for the development of a symptomatic disease.

3.947 The SUMO Conjugating Enzyme Ubc9 is a Regulator of GLUT4 Turnover and Targeting to the Insulin-Responsive Storage Compartment in 3T3-L1 Adipocytes
Liu, L-B., Omatra, W., Kojima, I. and Shibata, H.
*Diabetes, **56**, 1977-1985 (2007)*

The small ubiquitin-related modifier (SUMO) conjugating enzyme Ubc9 has been shown to upregulate GLUT4 in L6 myoblast cells, although the mechanism of action has remained undefined. Here we investigated the physiological significance of Ubc9 in GLUT4 turnover and subcellular targeting by adenovirus vector–mediated overexpression and by small interfering RNA (siRNA)-mediated gene silencing of Ubc9 in 3T3-L1 adipocytes. Overexpression of Ubc9 resulted in an inhibition of GLUT4 degradation and promoted its targeting to the unique insulin-responsive GLUT4 storage compartment (GSC), leading to an increase in GLUT4 amount and insulin-responsive glucose transport in 3T3-L1 adipocytes. Overexpression of Ubc9 also antagonized GLUT4 downregulation and its selective loss in GSC induced by long-term insulin stimulation. By contrast, siRNA-mediated depletion of Ubc9 accelerated GLUT4 degradation and decreased the amount of the transporter, concurrent with its selective loss in GSC, which resulted in attenuated insulin-responsive glucose transport. Intriguingly, overexpression of the catalytically inactive mutant Ubc9-C93A produced effects indistinguishable from those with wild-type Ubc9, suggesting that Ubc9 regulates GLUT4 turnover and targeting to GSC by a mechanism independent of its catalytic activity. Thus, Ubc9 is a pivotal regulator of the insulin sensitivity of glucose transport in adipocytes.

3.948 Core Protein Machinery for Mammalian Phosphatidylinositol 3,5-Bisphosphate Synthesis and Turnover That Regulates the Progression of Endosomal Transport: NOVEL SAC PHOSPHATASE JOINS THE ArPIKfyve-PIKfyve COMPLEX
Sbrissa, D. et al
*J. Biol. Chem., **282(33)**, 23878-23891 (2007)*

Perturbations in phosphatidylinositol 3,5-bisphosphate (PtdIns(3,5)P_2)-synthesizing enzymes result in enlarged endocytic organelles from yeast to humans, indicating evolutionarily conserved function of PtdIns(3,5)P_2 in endosome-related events. This is reinforced by the structural and functional homology of yeast Vac14 and human Vac14 (ArPIKfyve), which activate yeast and mammalian PtdIns(3,5)P_2-producing enzymes, Fab1 and PIKfyve, respectively. In yeast, PtdIns(3,5)P_2-specific phosphatase, Fig4, in association with Vac14, turns over PtdIns(3,5)P_2, but whether such a mechanism operates in mammalian cells and what the identity of mammalian Fig4 may be are unknown. Here we have identified and characterized Sac3, a Sac domain phosphatase, as the Fig4 mammalian counterpart. Endogenous Sac3, a widespread 97-kDa protein, formed a stable ternary complex with ArPIKfyve and PIKfyve. Concordantly, Sac3 cofractionated and colocalized with ArPIKfyve and PIKfyve. The intrinsic $Sac3^{WT}$ phosphatase activity preferably hydrolyzed PtdIns(3,5)P_2 *in vitro*, although the other D5-phosphorylated polyphosphoinositides were also substrates. Ablation of endogenous Sac3 by short interfering RNAs elevated PtdIns(3,5)P_2 in ^{32}P-labeled HEK293 cells. Ectopically expressed $Sac3^{WT}$ in COS cells colocalized with and dilated EEA1-positive endosomes, consistent with the PtdIns(3,5)P_2 requirement in early endosome dynamics. *In vitro* reconstitution of carrier vesicle formation from donor early endosomes revealed a gain of function upon Sac3 loss, whereas PIKfyve or ArPIKfyve protein depletion produced a loss of function. These data demonstrate a coupling between the machinery for PtdIns(3,5)P_2 synthesis and

turnover achieved through a physical assembly of PIKfyve, ArPIKfyve, and Sac3. We suggest that the tight regulation in PtdIns(3,5)P_2 homeostasis is mechanistically linked to early endosome dynamics in the course of cargo transport.

3.949 Catalase Takes Part in Rat Liver Mitochondria Oxidative Stress Defense
Salvi, M. et al
J. Biol. Chem., ***282(33)***, *24407-24451 (2007)*

Highly purified rat liver mitochondria (RLM) when exposed to *tert*-butylhydroperoxide undergo matrix swelling, membrane potential collapse, and oxidation of glutathione and pyridine nucleotides, all events attributable to the induction of mitochondrial permeability transition. Instead, RLM, if treated with the same or higher amounts of H_2O_2 or tyramine, are insensitive or only partially sensitive, respectively, to mitochondrial permeability transition. In addition, the block of respiration by antimycin A added to RLM respiring in state 4 conditions, or the addition of H_2O_2, results in O_2 generation, which is blocked by the catalase inhibitors aminotriazole or KCN. In this regard, H_2O_2 decomposition yields molecular oxygen in a 2:1 stoichiometry, consistent with a catalatic mechanism with a rate constant of 0.0346 s^{-1}. The rate of H_2O_2 consumption is not influenced by respiratory substrates, succinate or glutamate-malate, nor by *N*-ethylmaleimide, suggesting that cytochrome *c* oxidase and the glutathione-glutathione peroxidase system are not significantly involved in this process. Instead, H_2O_2 consumption is considerably inhibited by KCN or aminotriazole, indicating activity by a hemoprotein. All these observations are compatible with the presence of endogenous heme-containing catalase with an activity of 825 ± 15 units, which contributes to mitochondrial protection against endogenous or exogenous H_2O_2. Mitochondrial catalase in liver most probably represents regulatory control of bioenergetic metabolism, but it may also be proposed for new therapeutic strategies against liver diseases. The constitutive presence of catalase inside mitochondria is demonstrated by several methodological approaches as follows: biochemical fractionating, proteinase K sensitivity, and immunogold electron microscopy on isolated RLM and whole rat liver tissue.

3.950 Cell-Surface Thioredoxin-1: Possible Involvement in Thiol-Mediated Leukocyte-Endothelial Cell Interaction Through Lipid Rafts
Hara, T. et al
Antioxidants & Redox Signaling, ***9(9)***, *1427-1437 (2007)*

Human thioredoxin-1 (hTrx) exhibits a disulfide reducing activity and was originally identified as a soluble cytokine-like factor secreted from cells of a human T-cell leukemia virus type I (HTLV-I)-transformed cell line. Recent studies have revealed that endogenous Trx plays an important role in cytoprotection against various oxidative stress–associated disorders. However, the function of exogenous Trx is still not fully understood. We report here that a cysteine-modified mutant of recombinant human Trx (rhTrx-C35S) binds to human umbilical vein endothelial cells (HUVECs) as well as stimulated T cells and rapidly enters these cells *via* lipid rafts. In addition, we found that endogenous Trx is expressed on the surface of HUVECs, including lipid rafts. These events suggest cell-surface Trx as a possible target of rhTrx-C35S. Furthermore, we found that anti-human Trx mouse monoclonal antibody inhibits adherence of LPS-stimulated human peripheral blood polymorphonuclear cells (PMNs) to HUVECs. This adherence was also suppressed by a recombinant human Trx (rhTrx), but not by a mutant rhTrx (rhTrx-C32S/C35S) with no reducing activity. Cell-surface Trx may be involved in the process of interaction between PMNs and HUVECs and a possible target of cysteine-modified exogenous Trx as well as wild-type exogenous Trx through redox regulation.

3.951 Lipid Raft–Mediated Uptake of Cysteine-Modified Thioredoxin-1: Apoptosis Enhancement by Inhibiting the Endogenous Thioredoxin-1
Kondo, N. et al
Antioxidants & Redox Signaling, ***9(9)***, *1439-1448 (2007)*

Thioredoxin-1 (TRX) plays important roles in cellular signaling by controlling the redox state of cysteine residues in target proteins. TRX is released in response to oxidative stress and shows various biologic functions from the extracellular environment. However, the mechanism by which extracellular TRX transduces the signal into the cells remains unclear. Here we report that the cysteine modification at the active site of TRX promotes the internalization of TRX into the cells. TRX-C35S, in which the cysteine at residue 35 of the active site was replaced with serine, was internalized more effectively than wild-type TRX in human T-cell leukemia virus–transformed T cells. TRX-C35S bound rapidly to the cell surface and was internalized into the cells dependent on lipid rafts in the plasma membrane. This process was

inhibited by wild-type TRX, reducing reagents such as dithiothreitol, and methyl-β-cyclodextrin, which disrupts lipid rafts. Moreover, the internalized TRX-C35S binds to endogenous TRX, resulting in the generation of intracellular reactive oxygen species (ROS) and enhanced *cis*-diamine-dichloroplatinum (II) (CDDP)-induced apoptosis *via* a ROS-mediated pathway involving apoptosis signal-regulating kinase-1 (ASK-1) activation. These findings suggest that the cysteine at the active site of TRX plays a key role in the internalization and signal transduction of extracellular TRX into the cells.

3.952 P-Glycoprotein is not present in mitochondrial membranes
Paterson, J.K. and Gottesman, M.M.
*Exp. Cell Res., **313(14)**, 3100-3103 (2007)*

Recent reports have indicated the presence of P-glycoprotein in crude mitochondrial membrane fractions, leading to the assumption that P-glycoprotein is present in mitochondrial membranes, and may be involved in transport across these membranes. To determine the validity of this claim, two cell lines overexpressing endogenous P-glycoprotein were investigated. Using various centrifugation steps, mitochondria were purified from these cells and analyzed by Western blot reaction with the anti-P-glycoprotein antibody C219 and organelle-specific antibodies. While P-glycoprotein is present in crude mitochondrial fractions, these fractions are contaminated with plasma membranes. Further purification of the mitochondria to remove plasma membranes revealed that P-glycoprotein is not expressed in mitochondria of the KB-V1 (vinblastine-resistant KB-3-1 cells) or MCF-7^{ADR} (adriamycin-resistant MCF-7 cells) cell lines. To further substantiate these findings, we used confocal microscopy and the anti-P-glycoprotein antibody 17F9. This demonstrated that in intact cells, P-glycoprotein is not present in mitochondria and is primarily localized to the plasma membrane. These findings are consistent with the role of P-glycoprotein in conferring multidrug resistance by decreasing cellular drug accumulation. Therefore, contrary to previous speculation, P-glycoprotein does not confer cellular protection by residing in mitochondrial membranes.

3.953 Ubiquitination of Human Immunodeficiency Virus Type 1 Gag Is Highly Dependent on Gag Membrane Association
Jäger, S., Gottwein, E. and Kräusslich, H-G.
*J. Virol., **81(17)**, 9193-9201 (2007)*

Ubiquitin is important for the release of human immunodeficiency virus 1 (HIV-1) and several other retroviruses. All major domains of the HIV-1 Gag protein are monoubiquitinated, but the modifying machinery and the function of HIV-1 Gag ubiquitination remain unclear. Here, we show that the induction of a late budding arrest by mutation of the HIV-1 PTAP motif or by specific inhibition of selected ESCRT components leads to an increase of Gag-ubiquitin conjugates in cells, which coincides with an accumulation of detergent-insoluble, multimerized Gag at the plasma membrane. Membrane flotation experiments revealed that ubiquitinated Gag is highly enriched in membrane-bound fractions. Based on these findings, we propose that a blocking of virus release results in increased Gag ubiquitination as a consequence of its prolonged membrane association. Consistent with this, ubiquitination of a membrane-binding-defective (G2A)Gag mutant was dramatically reduced and the ubiquitination levels of truncated Gag proteins correlated with their abilities to bind to membranes. We therefore propose that membrane association and multimerization of HIV-1 Gag proteins, rather than a specific motif within Gag, trigger recognition by the cellular ubiquitination machinery.

3.954 Organellar proteomics to create the cell map
Au, C.E. et al
*Current Opinion in Cell Biology, **19**, 376-385 (2007)*

The elucidation of a complete, accurate, and permanent representation of the proteome of the mammalian cell may be achievable piecemeal by an organellar based approach. The small volume of organelles assures high protein concentrations. Providing isolated organelles are homogenous, this assures reliable protein characterization within the sensitivity and dynamic range limits of current mass spec based analysis. The stochastic aspect of peptide selection by tandem mass spectrometry for sequence determination by fragmentation is dealt with by multiple biological replicates as well as by prior protein separation on 1-D gels. Applications of this methodology to isolated synaptic vesicles, clathrin coated vesicles, endosomes, phagosomes, endoplasmic reticulum, and Golgi apparatus, as well as Golgi-derived COPI vesicles, have led to mechanistic insight into the identity and function of these organelles.

3.955 Cholesterol-Dependent and -Independent CD40 Internalization and Signaling Activation in Cardiovascular Endothelial Cells

Chen, J., Chen, L., Wang, G. and Tang, H.

*Artioscler. Thtomb. Vasc. Biol., **27**, 2005-2013 (2007)*

***Objective*—** It remains elusive how CD40 endocytosis or clustering on the cell surface is induced by different forms of CD40 agonist. This study aims to investigate whether lipid rafts differentially regulate CD40 traffic and signaling in proinflammatory activation of cardiovascular endothelial cells (ECs).
***Methods and Results*—** Using fluorescent microscopy and flow cytometry, we demonstrated that soluble CD40L and agonistic antibody G28.5 induced CD40 internalization via clathrin-independent pathway. Furthermore, depletion of cholesterol by methyl-ß-cyclodextrin (MCD) or siRNA knockdown of caveolin-1 efficiently blocked CD40 internalization, suggesting that caveolae-rafts pathway regulates CD40 internalization. In contrast, a membrane-bound CD40L mimic (megamer) triggered aggregation of CD40 rafts outside of the conventional cholera toxin B subunit-positive lipid rafts resistant to cholesterol depletion. Finally, both G28.5 and megamer induced CD40 translocation to Brij58-insoluble, low buoyant density rafts, a movement insensitive to cholesterol depletion. However, MCD effectively inhibited G28.5 but not megamer-induced CD40 activation, and such inhibition could be alleviated by cholesterol reconstitution, suggesting that 2 different raft structures of CD40 induced by G28.5 or megamer possess differential sensitivity to cellular cholesterol levels in downstream signaling.
***Conclusions*—** Depending on different forms of agonist, CD40 uses either a cholesterol-dependent or -independent mode for trafficking and signaling in ECs.
Although activated CD40 can translocate to lipid rafts despite cholesterol depletion, different forms of CD40L, either soluble or membrane-bound, required distinct membrane constituents and microdomains for CD40 internalization and signaling activation. In particular, stimulation with G28.5, but not membrane-bound CD40L, required cellular cholesterol for CD40 internalization and downstream signaling.

3.956 Localization of the Mouse 5-Hydroxytryptamine1A Receptor in Lipid Microdomains Depends on Its Palmitoylation and Is Involved in Receptor-Mediated Signaling

Renner, U. et al

*Mol. Pharmacol., **72(3)**, 502-513 (2007)*

In the present study, we have used wild-type and palmitoylation-deficient mouse 5-hydroxytryptamine$_{1A}$ receptor (5-HT1A) receptors fused to the yellow fluorescent protein- and the cyan fluorescent protein (CFP)-tagged α_{i3} subunit of heterotrimeric G-protein to study spatiotemporal distribution of the 5-HT1A-mediated signaling in living cells. We also addressed the question on the molecular mechanisms by which receptor palmitoylation may regulate communication between receptors and G_i-proteins. Our data demonstrate that activation of the 5-HT1A receptor caused a partial release of $G\alpha_i$ protein into the cytoplasm and that this translocation is accompanied by a significant increase of the intracellular Ca^{2+} concentration. In contrast, acylation-deficient 5-HT1A mutants failed to reproduce both $G\alpha_{i3}$-CFP relocation and changes in $[Ca^{2+}]_i$ upon agonist stimulation. By using gradient centrifugation and copatching assays, we also demonstrate that a significant fraction of the 5-HT1A receptor resides in membrane rafts, whereas the yield of the palmitoylation-deficient receptor in these membrane microdomains is reduced considerably. Our results suggest that receptor palmitoylation serves as a targeting signal responsible for the retention of the 5-HT1A receptor in membrane rafts. More importantly, the raft localization of the 5-HT1A receptor seems to be involved in receptor-mediated signaling.

3.957 Activated Ezrin Promotes Cell Migration through Recruitment of the GEF Dbl to Lipid Rafts and Preferential Downstream Activation of Cdc42

Prag, S. et al

*Mol. Biol. Cell, **18**, 2935-2948 (2007)*

Establishment of polarized cell morphology is a critical factor for migration and requires precise spatial and temporal activation of the Rho GTPases. Here, we describe a novel role of the actin-binding ezrin/radixin/moesin (ERM)-protein ezrin to be involved in recruiting Cdc42, but not Rac1, to lipid raft microdomains, as well as the subsequent activation of this Rho GTPase and the downstream effector p21-activated kinase (PAK)1, as shown by fluorescence lifetime imaging microscopy. The establishment of a leading plasma membrane and the polarized morphology necessary for random migration are also dependent on ERM function and Cdc42 in motile breast carcinoma cells. Mechanistically, we show that the recruitment of the ERM-interacting Rho/Cdc42-specific guanine nucleotide exchange factor Dbl to the plasma membrane and to lipid raft microdomains requires the phosphorylated, active conformer of ezrin,

which serves to tether the plasma membrane or its subdomains to the cytoskeleton. Together these data suggest a mechanism whereby precise spatial guanine nucleotide exchange of Cdc42 by Dbl is dependent on functional ERM proteins and is important for directional cell migration.

3.958 Human Papillomavirus Type 31 Uses a Caveolin 1- and Dynamin 2-Mediated Entry Pathway for Infection of Human Keratinocytes
Smith, J.L., Campos, S.K. and Ozbun, M.A.
J. Virol., ***81(18)****, 9922-9931 (2007)*

Papillomaviruses are species-specific and epitheliotropic DNA viruses that cause tumors in their natural hosts. Certain infections with genital human papillomavirus (HPV) types are causally related to cervical cancer development. Most papillomaviruses are thought to infect cells via a clathrin-dependent pathway, yet no studies have determined the entry route in permissive host epithelial cells. Employing fluorescently labeled and native virions, we tested the effects of dominant-negative and biochemical inhibitors of cellular endocytosis pathways. Infections of human keratinocytes, a natural host cell type for HPVs, were assessed visually and by infectious entry assays. We found that HPV type 31 (HPV31) entry and initiation of early infection events require both caveolin 1 and dynamin 2 and occur independently of clathrin-mediated endocytosis. Treatment with chlorpromazine and filipin had opposing effects on HPV31 and HPV16 infection. HPV31 entry was remarkably slow, with a half-time of ≈14 h, whereas the entry half-time of HPV16 was 4 h. Consistent with a caveola-mediated entry pathway for HPV31, the virions associated with detergent-resistant lipid rafts. During a 16-h microscopic tracking of HPV31 and HPV16 virions, no colocalization of the two viral types was observed. These data suggest that HPV31 and HPV16 virions use distinct routes for host epithelial cell entry.

3.959 Detergent resistance as a tool in membrane research
Lingwood, D. and Simons, K.
Nature Protocols, ***2(9)****, 2159-2165 (2007)*

The biological membrane is a complicated matrix wherein different lipid environments are thought to exist. The more ordered or raft environment has been perceived biochemically accessible via its relative resistance to detergent. This paper outlines the protocols developed in our laboratory for the analysis of such detergent-resistant membranes (DRMs). We stress the fact that DRMs are artifactual in nature and should not be equivocated to lipid rafts, their usefulness being limited to assigning raft-association potential most convincingly when changes in DRM composition are induced by biochemically/physiologically relevant events. These protocols are completed in 1–2 d.

3.960 Light-induced recruitment of INAD-signaling complexes to detergent-resistant lipid rafts in Drosophila photoreceptors
Sanxaridis, P.D. et al
Mol. Cell. Neurosci., ***36(1)****, 36-46 (2007)*

Here, we reveal a novel feature of the dynamic organization of signaling components in *Drosophila* photoreceptors. We show that the multi-PDZ protein INAD and its target proteins undergo light-induced recruitment to detergent-resistant membrane (DRM) rafts. Reduction of ergosterol, considered to be a key component of lipid rafts in *Drosophila*, resulted in a loss of INAD-signaling complexes associated with DRM fractions. Genetic analysis demonstrated that translocation of INAD-signaling complexes to DRM rafts requires activation of the entire phototransduction cascade, while constitutive activation of the light-activated channels resulted in recruitment of complexes to DRM rafts in the dark. Mutations affecting INAD and TRP showed that PDZ4 and PDZ5 domains of INAD, as well as the INAD–TRP interaction, are required for translocation of components to DRM rafts. Finally, selective recruitment of phosphorylated, and therefore activatable, eye-PKC to DRM rafts suggests that DRM domains are likely to function in signaling, rather than trafficking.

3.961 Involvement of cell surface ATP synthase in flow-induced ATP release by vascular endothelial cells
Yamamoto, K. et al
*Am. J. Physiol. Heart Circ. Physiol.,****293,*** *H1646-H1653 (2007)*

Endothelial cells (ECs) release ATP in response to shear stress, a mechanical force generated by blood flow, and the ATP released modulates EC functions through activation of purinoceptors. The molecular mechanism of the shear stress-induced ATP release, however, has not been fully elucidated. In this study,

we have demonstrated that cell surface ATP synthase is involved in shear stress-induced ATP release. Immunofluorescence staining of human pulmonary arterial ECs (HPAECs) showed that cell surface ATP synthase is distributed in lipid rafts and co-localized with caveolin-1, a marker protein of caveolae. Immunoprecipitation indicated that cell surface ATP synthase and caveolin-1 are physically associated. Measurement of the extracellular metabolism of [^{3}H]ADP confirmed that cell surface ATP synthase is active in ATP generation. When exposed to shear stress, HPAECs released ATP in a dose-dependent manner, and the ATP release was markedly suppressed by the membrane-impermeable ATP synthase inhibitors angiostatin and piceatannol and by an anti-ATP synthase antibody. Depletion of plasma membrane cholesterol with methyl-β-cyclodextrin (MβCD) disrupted lipid rafts and abolished co-localization of ATP synthase with caveolin-1, which resulted in a marked reduction in shear stress-induced ATP release. Pretreatment of the cells with cholesterol prevented these effects of MβCD. Downregulation of caveolin-1 expression by transfection of caveolin-1 siRNA also markedly suppressed ATP-releasing responses to shear stress. Neither MβCD, MβCD plus cholesterol, nor caveolin-1 siRNA had any effect on the amount of cell surface ATP synthase. These results suggest that the localization and targeting of ATP synthase to caveolae/lipid rafts is critical for shear stress-induced ATP release by HPAECs.

3.962 Lipid Raft–Specific Knockdown of Src Family Kinase Activity Inhibits Cell Adhesion and Cell Cycle Progression of Breast Cancer Cells
Hitosugi, T., Sato, M., Sasaki, K and Umezawa, Y.
Cancer Res., ***(67/17)***, *8139-8148 (2007)*

Src family kinase (SFK) is known to control various cell functions, but the significance of the location of its activation was largely unknown. We herein revealed that SFK activation occurs in lipid rafts. Based on this finding, we have developed a lipid raft–targeted SFK inhibitory fusion protein (LRT-SIFP) that inhibits the SFK activity in lipid rafts. LRT-SIFP has a peptide inhibitor of SFK and a lipid raft–targeting sequence in which two cysteine residues are palmitoylated for clustering in lipid rafts. LRT-SIFP was found to inhibit cell adhesion and cell cycle progression of human breast cancer cell lines MCF-7 and MDA-MB231. On the other hand, the cell functions of MCF-7 cells were found to be not affected with a previously developed peptide inhibitor of SFK that lacks the lipid raft–targeting sequence. In addition, when we replaced the targeting sequence of LRT-SIFP with the consensus sequence for geranylgeranylation to make LRT-SIFP unable to cluster in lipid rafts, this mutated LRT-SIFP did not show any effect on the above cell functions of MCF-7 cells. Furthermore, in contrast to the breast cancer cell lines, LRT-SIFP did not show any inhibitory effect on cell adhesion and cell cycle progression of human normal cell line HEK293. The present lipid raft–specific knockdown of SFK activity would potentially be useful for selective cancer therapy to prevent tumorigenesis and metastasis of breast cancer cells.

3.963 Intracellular Trafficking of Pseudomonas ExoS, a Type III Cytotoxin
Deng, Q., Zhang, Y. and Barbier, J.T.
Traffic, ***8***, *1331-1345 (2007)*

Pseudomonas aeruginosa ExoS is a bifunctional type III cytotoxin that disrupts Ras- and Rho-signaling pathways in mammalian cells. A hydrophobic region (residues 51–77, termed the membrane localization domain) targets ExoS to the plasma membrane (PM) and late endosomes of host cells. In the current study, metabolic inhibitors and dominant-negative proteins that disrupt known vesicle-trafficking pathways were used to define the intracellular trafficking of ExoS. Release of ExoS from PM was independent of dynamin and ADP ribosylation factor 6 but inhibited by methyl-β-cyclodextrin, a cholesterol-depleting reagent, and perinuclear localization of ExoS was disrupted by nocodazole. p50 dynamitin, a dynein inhibitor partially disrupted perinuclear localization of ExoS. Methyl-β-cyclodextrin and nocodazole inhibited the ability of type-III-delivered ExoS to ADP-ribosylated Golgi/endoplasmic reticulum-resident Ras. Methyl-β-cyclodextrin also relocated ExoS from the perinuclear region to the PM, indicating that ExoS can cycle through anterograde as well as through retrograde trafficking pathways. These findings show that ExoS endocytosis is cholesterol dependent, and it utilizes host microtubules, for intracellular trafficking. Understanding how type III cytotoxins enter and traffic within mammalian cells may identify new targets for therapeutic intervention of gram-negative bacterial pathogens.

3.964 Biochemical consequences of the NOS3 Glu298Asp variation in human endothelium: altered caveolar localization and impaired response to shear
Joshi, M.S., Mineo, C., Shaul, P.W. and Bauer, J.A.
FASEB J., ***21***, *2655-2663 (2007)*

Human endothelial nitric oxide synthase (NOS3) gene polymorphism at Exon 7 (Glu298Asp) has been linked to vascular endothelial dysfunction, but the mechanisms are not defined. Shear is a key modulator of NOS3 function *in vivo* and association with caveolae is important for the control of NOS3 protein activity. Here we tested the hypothesis that altered enrichment of NOS3 in the caveolar membrane defines Glu298Asp genotype-specific responses and NOS3 activity. Basal caveolar membrane enrichment was carried out to quantitate the NOS3 enrichment in caveolae. Cells were subjected to shear and NOS3 protein levels, phosphorylation, enzyme function were investigated. Variant genotypes had lower NOx production pre- and post-shear, but no genotype-dependent alterations in pNOS3 were observed. Asp variants had significantly lower NOS3 enrichment in the caveolar membrane fraction. Further, immunoprecipitation studies demonstrated that Asp variants had substantially less NOS3/Cav-1 association (~40%) during static conditions. Furthermore, acute shear causes impaired NOS3/Cav-1 dissociation in Asp variants. The results from immunoprecipitation studies were in complete agreement with caveolar membrane preparation findings. Collectively, these data demonstrate functional consequences of the Glu298Asp NOS3 variation and further define disruption of NOS3 caveolar localization and shear-induced mobilization as the primary mechanism responsible for these differences.—Joshi, M. S., Mineo, C., Shaul, P. W., Bauer, J. A. Biochemical consequences of the NOS3 Glu298Asp variation in human endothelium: altered caveolar localization and impaired response to shear.

3.965 Peroxisomes Contain a Specific Phytanoyl-CoA/Pristanoyl-CoA Thioesterase Acting as a Novel Auxiliary Enzyme in α- and β-Oxidation of Methyl-branched Fatty Acids in Mouse
Westin, M.A., Hunt, M.C. and Elexson, S.E.H.
J. Biol. Chem., ***282(37)***, *26707-26716 (2007)*

Phytanic acid and pristanic acid are derived from phytol, which enter the body via the diet. Phytanic acid contains a methyl group in position three and, therefore, cannot undergo β-oxidation directly but instead must first undergo α-oxidation to pristanic acid, which then enters β-oxidation. Both these pathways occur in peroxisomes, and in this study we have identified a novel peroxisomal acyl-CoA thioesterase named ACOT6, which we show is specifically involved in phytanic acid and pristanic acid metabolism. Sequence analysis of ACOT6 revealed a putative peroxisomal targeting signal at the C-terminal end, and cellular localization experiments verified it as a peroxisomal enzyme. Subcellular fractionation experiments showed that peroxisomes contain by far the highest phytanoyl-CoA/pristanoyl-CoA thioesterase activity in the cell, which could be almost completely immunoprecipitated using an ACOT6 antibody. *Acot6* mRNA was mainly expressed in white adipose tissue and was co-expressed in tissues with *Acox3* (the pristanoyl-CoA oxidase). Furthermore, *Acot6* was identified as a target gene of the peroxisome proliferator-activated receptor α(PPARα) and is up-regulated in mouse liver in a PPARα-dependent manner.

3.966 Nuclear Import and Export of Venezuelan Equine Encephalitis Virus Nonstructural Protein 2
Montgomery, S.A. and Johnston, R.E.
J. Virol., ***81(19)***, *10268-10279 (2007)*

Many RNA viruses, which replicate predominantly in the cytoplasm, have nuclear components that contribute to their life cycle or pathogenesis. We investigated the intracellular localization of the multifunctional nonstructural protein 2 (nsP2) in mammalian cells infected with Venezuelan equine encephalitis virus (VEE), an important, naturally emerging zoonotic alphavirus. VEE nsP2 localizes to both the cytoplasm and the nucleus of mammalian cells in the context of infection and also when expressed alone. Through the analysis of a series of enhanced green fluorescent protein fusions, a segment of nsP2 that completely localizes to the nucleus of mammalian cells was identified. Within this region, mutation of the putative nuclear localization signal (NLS) PGKMV diminished, but did not obliterate, the ability of the protein to localize to the nucleus, suggesting that this sequence contributes to the nuclear localization of VEE nsP2. Furthermore, VEE nsP2 specifically interacted with the nuclear import protein karyopherin-α1 but not with karyopherin-α2, -3, or -4, suggesting that karyopherin-α1 transports nsP2 to the nucleus during infection. Additionally, a novel nuclear export signal (NES) was identified, which included residues L526 and L528 of VEE nsP2. Leptomycin B treatment resulted in nuclear accumulation of nsP2, demonstrating that nuclear export of nsP2 is mediated via the CRM1 nuclear export pathway. Disruption of either the NLS or the NES in nsP2 compromised essential viral functions. Taken together, these results establish the bidirectional transport of nsP2 across the nuclear membrane, suggesting that a critical function of nsP2 during infection involves its shuttling between the cytoplasm and the nucleus.

3.967 Association of the Astrovirus Structural Protein VP90 with Membranes Plays a Role in Virus Morphogenesis

Mendez, E., Aguirre-Crespo, G., Zavala, G. and Arias, C.F.
J. Virol., ***81(19)***, *10649-10658 (2007)*

VP90, the capsid polyprotein precursor of human astrovirus Yuc8, is assembled into viral particles, and its processing at the carboxy terminus by cellular caspases, to yield VP70, has been correlated with the cell release of the virus. Here, we characterized the effect of the VP90-VP70 processing on the properties of these proteins, as well as on their intracellular distribution. VP90 was found in membrane-enriched fractions (^{m}VP90), as well as in fractions enriched in cytosolic proteins (^{c}VP90), while VP70 was found exclusively in the latter fractions. Upon trypsin activation, infectivity was detected in all VP90-containing fractions, confirming that both ^{m}VP90 and ^{c}VP90 are able to assemble into particles; however, the two forms of VP90 showed differential sensitivities to trypsin, especially at their carboxy termini, which in the case of ^{m}VP90 was shown to remain membrane associated after protease digestion. Structural protein oligomers were detected in purified VP70-containing viruses, as well as in membrane-enriched fractions, but they were less evident in cytosolic fractions. Ultrastructural studies of infected cells revealed different types of viral particles, some of which appeared to be associated with membranes. By immunoelectron microscopy, structural proteins were shown to form virus particles in clusters and to associate with the edges of vesicles induced during infection, which also appear to contain subviral particles inside. Nonstructural proteins and viral RNA colocalized with ^{m}VP90, but not with ^{c}VP90, suggesting that ^{m}VP90 might represent the form of the protein that is initially assembled into particles, at the sites where the virus genome is being replicated.

3.968 Intracellular HIV-1 Gag localization is impaired by mutations in the nucleocapsid zinc fingers

Grigorov, B. et al
Retrovirology, ***4(54)***, *1-12 (2007)*

Background
The HIV-1 nucleocapsid protein (NC) is formed of two CCHC zinc fingers flanked by highly basic regions. HIV-1 NC plays key roles in virus structure and replication *via* its nucleic acid binding and chaperoning properties. In fact, NC controls proviral DNA synthesis by reverse transcriptase (RT), gRNA dimerization and packaging, and virion assembly.
Results
We previously reported a role for the first NC zinc finger in virion structure and replication [1]. To investigate the role of both NC zinc fingers in intracellular Gag trafficking, and in virion assembly, we generated series of NC zinc fingers mutations. Results show that all Zinc finger mutations have a negative impact on virion biogenesis and maturation and rendered defective the mutant viruses. The NC zinc finger mutations caused an intracellular accumulation of Gag, which was found either diffuse in the cytoplasm or at the plasma membrane but not associated with endosomal membranes as for wild type Gag. Evidences are also provided showing that the intracellular interactions between NC-mutated Gag and the gRNA were impaired.
Conclusion
These results show that Gag oligomerization mediated by gRNA-NC interactions is required for correct Gag trafficking, and assembly in HIV-1 producing cells and the release of infectious viruses.

3.969 Effects of a New Bioactive Lipid-Based Drug Carrier on Cultured Hepatic Stellate Cells and Liver Fibrosis in Bile Duct-Ligated Rats

Adrian, J.E. et al
J. Pharmacol. Exp. Ther., ***321(2)***, *536-543 (2007)*

In the fibrotic liver, hepatic stellate cells (HSC) produce large amounts of collagen and secrete variety of mediators that promote development of fibrosis in this organ. Therefore, these cells are considered an attractive target for antifibrotic therapies. We incorporated the bioactive lipid dilinoleoylphosphatidylcholine (DLPC) into the membrane of liposomes, and then we evaluated its effect on hepatic stellate cell activation and liver fibrosis. To target DLPC-liposomes to HSC, human serum albumin modified with mannose 6-phosphate (M6P-HSA) was coupled to the surface of these liposomes. In vitro, the effects of the carrier were determined in primary cultures of HSC, Kupffer cells, and liver endothelial cells using real-time reverse transcription-polymerase chain reaction. In vivo DLPC-liposomes were tested in bile duct-ligated rats. Targeted M6P-HSA-DLPC-liposomes and DLPC-liposomes significantly reduced gene expression levels for collagen 1α1, α-smooth muscle actin (α-SMA), and

transforming growth factor-β (TGF-β) in cultured HSC. In fibrotic livers, DLPC-liposomes decreased gene expression for TGF-β and collagen 1α1 as well as α-SMA and collagen protein expression. In contrast, M6P-HSA-DLPC-liposomes enhanced expression of profibrotic and proinflammatory genes in vivo. In cultured Kupffer and endothelial cells M6P-HSA liposomes influenced the expression of proinflammatory genes. Both types of liposomes increased hepatocyte glycogen content in fibrotic livers, indicating improved functionality of the hepatocytes. We conclude that DLPC-containing liposomes attenuate activation of cultured HSC. In fibrotic livers, M6P-HSA-mediated activation of Kupffer and endothelial cells probably counteracts this beneficial effect of DLPC-liposomes. Therefore, these bioactive drug carriers modulate the activity of all liver cells during liver fibrosis.

3.970 Characterization of the Intracellular Proteolytic Cleavage of Myocilin and Identification of Calpain II as a Myocilin-processing Protease
Sanchez-Sanchez, F., Martinez-Redondo, F., Aroca-Aguilar, J.D., Coca-Prados, M. and Escrobano, J.
J. Biol. Chem., ***282(38)***, *27810-27824 (2007)*

MYOC, a gene involved in different types of glaucoma, encodes myocilin, a secreted glycoprotein of unknown function, consisting of an N-terminal leucine-zipper-like domain, a central linker region, and a C-terminal olfactomedin-like domain. Recently, we have shown that myocilin undergoes an intracellular endoproteolytic processing. We show herein that the proteolytic cleavage in the linker region splits the two terminal domains. The C-terminal domain is secreted to the culture medium, whereas the N-terminal domain mainly remains intracellularly retained. In transiently transfected 293T cells, the cleavage was prevented by calpain inhibitors, such as calpeptin, calpain inhibitor IV, and calpastatin. Since calpains are calcium-activated proteases, we analyzed how changes in either intra- or extracellular calcium affected the cleavage of myocilin. Intracellular ionomycin-induced calcium uptake enhanced myocilin cleavage, whereas chelation of extracellular calcium by EGTA inhibited the proteolytic processing. Calpains I and II cleaved myocilin *in vitro*. However, in cells in culture, only RNA interference knockdown of calpain II reduced myocilin processing. Subcellular fractionation and digestion of the obtained fractions with proteinase K showed that full-length myocilin resides in the lumen of the endoplasmic reticulum together with a subpopulation of calpain II. These data revealed that calpain II is responsible for the intracellular processing of myocilin in the lumen of the endoplasmic reticulum. We propose that this cleavage might regulate extracellular interactions of myocilin, contributing to the control of intraocular pressure.

3.971 HtrA2 Regulates β-Amyloid Precursor Protein (APP) Metabolism through Endoplasmic Reticulum-associated Degradation
Huttunen, H.J. et al
J. Biol. Chem., ***282(38)***, *28285-28295 (2007)*

Alzheimer disease-associated β-amyloid peptide is generated from its precursor protein APP. By using the yeast two-hybrid assay, here we identified HtrA2/Omi, a stress-responsive chaperone-protease as a protein binding to the N-terminal cysteinerich region of APP. HtrA2 coimmunoprecipitates exclusively with immature APP from cell lysates as well as mouse brain extracts and degrades APP *in vitro*. A subpopulation of HtrA2 localizes to the cytosolic side of the endoplasmic reticulum (ER) membrane where it contributes to ER-associated degradation of APP together with the proteasome. Inhibition of the proteasome results in accumulation of retrotranslocated forms of APP and increased association of APP with HtrA2 and Derlin-1 in microsomal membranes. In cells lacking HtrA2, APP holoprotein is stabilized and accumulates in the early secretory pathway correlating with elevated levels of APP C-terminal fragments and increased Aβ secretion. Inhibition of ER-associated degradation (either HtrA2 or proteasome) promotes binding of APP to the COPII protein Sec23 suggesting enhanced trafficking of APP out of the ER. Based on these results we suggest a novel function for HtrA2 as a regulator of APP metabolism through ER-associated degradation.

3.972 Anionic Lipid Interaction Induces Prion Protein Conformational Change
Wang, F., Wang, X. and Ma, J.
FASEB J., ***21***, *781.3 (2007)*

The conversion of the prion protein (PrP) to the pathogenic PrP^{Sc} conformation plays a central role in prion disease. However, the precise mechanism underlying this process remains unclear. Here, we report the conformational conversion of PrP upon interaction with anionic lipids. After the discontinuous **iodixanol**

density gradient centrifugation, we found strong binding between PrP and negatively charged phospholipids, involving both electrostatic and hydrophobic interactions. Under physiologically relevant conditions, interactions with lipid were sufficient to convert full-length, α-helices rich recombinant mouse PrP to a conformation similar to PrP^{Sc}, with increased ß sheet content and a PrP^{Sc}-like proteinase K (PK)-resistant pattern. Conversion is greatly influenced by lipid headgroup structures and lipid vesicle compositions. When lipid vesicles are disrupted by detergent, aggregation is necessary to maintain the PK resistant conformation. Our results imply that the strong lipid-PrP interaction is sufficient to overcome the energy barrier between the two conformational states and support the notion that lipid membrane may play a role in PrP conformational change.

3.973 SVIP interacts with Derlin1 and regulates ER-associated degradation
Ballar, P. et al
FASEB J., ***21***, *808.3 (2007)*

Production of misfolded proteins in the endoplasmic reticulum (ER) underlies pathogenesis of many diseases. Cells utilize a process, called ER-associated degradation (ERAD) to eliminate misfolded ER proteins, thereby protecting against the toxicity of the defective proteins. However, the molecular mechanisms underlying the process of ERAD remain to be fully understood. Here, we report that the SVIP is specifically and highly expressed in mouse brain as revealed by mouse multi-tissue blotting. By **Opti-Prep** density gradient fractionation, we demonstrated that SVIP is co-fractionated with ERAD machineries, including Derlin1, Hrd1, and gp78. Co-immunoprecipitation shows that SVIP strongly interacts with Derlin1 and p97/VCP, but weakly with Hrd1 and gp78. SVIP is anchored to the ER membrane probably via myristoylation, since mutation of the putative myristoylation site impaired its ER localization. Further, we found that SVIP is upregulated by tunicamycin-induced ER stress both at mRNA and protein levels. Functionally, SVIP enhances the loading of polyubiquitinated proteins to p97/VCP, suggesting that SVIP may play a role in coupling ubiquitination with retrotranslocation of misfolded proteins during ERAD. Consistently, silencing of SVIP expression by RNA interference stabilizes ERAD substrate tyrosinase(C89R). These results suggest that SVIP may facilitate the coupling of ubiquitination with retrotranslocation during ERAD and might play a protective role in brain.

3.974 CFTR Inhibitory Factor (CIF) reduces the plasma membrane expression of CFTR by altering intracellular trafficking of CFTR to the lysosomal pathway
Bomberger, J.M. et al
FASEB J., ***21***, *944.4 (2007)*

The ΔF508-CFTR mutation, the most common gene mutation in cystic fibrosis (CF), results in diminished plasma membrane expression of CFTR, leading to loss of functional CFTR and altered mucociliary clearance. This impairment promotes chronic infection of CF patients by *P. aeruginosa*. Previously we reported that a secreted factor from *P. aeruginosa* (CIF) reduces CFTR-mediated chloride secretion and the plasma membrane expression of CFTR by decreasing endocytic recycling. The aim of the current study was to investigate the mechanism by which CIF reduces the endocytic recycling of CFTR. CIF applied to the apical side of polarized human airway epithelial cells reduced CFTR in the plasma membrane, followed by a subsequent increase in CFTR labeling in the endosomes, then lysosomes, as determined by **Optiprep** subcellular compartment fractionation experiments. Co-immunoprecipitation studies revealed that CIF decreased the association of CFTR with Rab11a, concurrent with an increase in association of CFTR with Rab4a and Rab7. Lysosomal inhibitors blocked the degradation of CFTR by CIF, whereas proteosomal inhibitors had no effect. These studies demonstrate that CIF induces a redistribution of CFTR trafficking from the endocytic recycling pathway to the degradative pathway. In addition, this data suggests that chronic infection of *P. aeruginosa* in the CF lung may impact the efficacy of therapeutics developed to increase plasma membrane expression of the ΔF508-CFTR.

3.975 Cellular spelunking: exploring adipocyte caveolae
Pilch, P.F. et al
J. Lipid Res., ***48***, *2103-2111 (2007)*

It has been known for decades that the adipocyte cell surface is particularly rich in small invaginations we now know to be caveolae. These structures are common to many cell types but are not ubiquitous. They have generated considerable curiosity, as manifested by the numerous publications on the topic that describe various, sometimes contradictory, caveolae functions. Here, we review the field from an "adipocentric" point of view and suggest that caveolae may have a function of particular use for the fat cell,

namely the modulation of fatty acid flux across the plasma membrane. Other functions for adipocyte caveolae that have been postulated include participation in signal transduction and membrane trafficking pathways, and it will require further experimental scrutiny to resolve controversies surrounding these possible activities.

3.976 Lifeguard/neuronal membrane protein 35 regulates Fas ligand-mediated apoptosis in neurons via microdomain recruitment
Fernandez, M. et al
J. Neurochem., ***103***, *190-203 (2007)*

Fas ligand (FasL)-receptor system plays an essential role in regulating cell death in the developing nervous system, and it has been implicated in neurodegenerative and inflammatory responses in the CNS. Lifeguard (LFG) is a protein highly expressed in the hippocampus and the cerebellum, and it shows a particularly interesting regulation by being up-regulated during postnatal development and in the adult. We show that over-expression of LFG protected cortical neurons from FasL-induced apoptosis and decreased caspase-activation. Reduction of endogenous LFG expression by small interfering RNA sensitized cerebellar granular neurons to FasL-induced cell death and caspase-8 activation, and also increased sensitivity of cortical neurons. In differentiated cerebellar granular neurons, protection from FasL-induced cell death could be attributed exclusively to LFG and appears to be independent of FLICE inhibitor protein. Thus, LFG is an endogenous inhibitor of FasL-mediated neuronal death and it mediates the FasL resistance of CNS differentiated neurons. Finally, we also demonstrate that LFG is detected in lipid rafts microdomains, where it may interact with Fas receptor and regulate FasL-activated signaling pathways.

3.977 Mannheimia haemolytica Leukotoxin Binds to Lipid Rafts in Bovine Lymphoblastoid Cells and Is Internalized in a Dynamin-2- and Clathrin-Dependent Manner
Atapatta, D.N. and Czuprynski, C.J.
Infect. Immun., ***75(10)***, *4719-4727 (2007)*

Mannheimia haemolytica is the principal bacterial pathogen of the bovine respiratory disease complex. Its most important virulence factor is a leukotoxin (LKT), which is a member of the RTX family of exotoxins produced by many gram-negative bacteria. Previous studies demonstrated that LKT binds to the ß$_2$-integrin LFA-1 (CD11a/CD18) on bovine leukocytes, resulting in cell death. In this study, we demonstrated that depletion of lipid rafts significantly decreases LKT-induced bovine lymphoblastoid cell (BL-3) death. After binding to BL-3 cells, some of the LKT relocated to lipid rafts in an LFA-1-independent manner. We hypothesized that after binding to LFA-1 on BL-3 cells, LKT moves to lipid rafts and clathrin-coated pits via a dynamic process that results in LKT internalization and cytotoxicity. Knocking down dynamin-2 by small interfering RNA reduced both LKT internalization and cytotoxicity. Similarly, expression of dominant negative Eps15 protein expression, which is required for clathrin coat formation, reduced LKT internalization and LKT-mediated cytotoxicity to BL-3 cells. Finally, we demonstrated that inhibiting actin polymerization reduced both LKT internalization and LKT-mediated cytotoxicity. These results suggest that both lipid rafts and clathrin-mediated mechanisms are important for LKT internalization and cytotoxicity in BL-3 cells and illustrate the complex nature of LKT internalization by the cytoskeletal network.

3.978 Phosphoinositide 3-Kinase-independent Non-genomic Signals Transit from the Androgen Receptor to Akt1 in Membrane Raft Microdomains
Cinar, B., Mukhopadhyay, N.K., Meng, G. and Freeman, M.R.
J. Biol. Chem., ***282(40)***, *29584-29593 (2007)*

The serine-threonine kinase, Akt1/protein kinase Bα is an important mediator of growth, survival, and metabolic signaling. Recent studies have implicated cholesterol-rich, lipid raft microdomains in survival signals mediated by Akt1. Here we address the role of lipid raft membranes as a potential site of intersection of androgenic and Akt1 signaling. A subpopulation of androgen receptor (AR) was found to localize to a lipid raft subcellular compartment in LNCaP prostate cancer cells. Endogenous AR interacted with endogenous Akt1 preferentially in lipid raft fractions and androgen substantially enhanced the interaction between the two proteins. The association of AR with Akt1 was inhibited by the anti-androgen, bicalutamide, but was not affected by inhibition of phosphoinositide 3-kinase (PI3K). Androgen promoted endogenous Akt1 activity in lipid raft fractions, in a PI3K-independent manner, within 10 min of treatment. Fusion of a lipid raft targeting sequence to AR enhanced localization of the receptor to rafts, and stimulated Akt1 activity in response to androgen, while reducing the cells' dependence on constitutive signaling

through PI3K for cell survival. These findings suggest that signals channeled through AR and Akt1 intersect by a mechanism involving formation within lipid raft membranes of an androgen-responsive, extranuclear AR/Akt1 complex. Our results indicate that cholesterol-rich membrane microdomains play a role in transmitting non-genomic signals involving androgen and the Akt pathway in prostate cancer cells.

3.979 Ablation of a small transmembrane protein of Trypanosoma brucei (TbVTC1) involved in the synthesis of polyphosphate alters acidocalcisome biogenesis and function, and leads to a cytokinesis defect

Fang, J., Rohloff, P., Miranda, K. And Docampo, R.
Biochem. J., ***407***, *161-170 (2007)*

Inorganic poly P (polyphosphate) is an abundant component of acidocalcisomes of *Trypanosoma brucei*. In the present study we report the presence of a protein homologous with the yeast Vtc1p (vacuolar transporter chaperone 1) in *T. brucei* that is essential for poly P synthesis, acidocalcisome biogenesis and cytokinesis. Localization studies in a cell line expressing a TbVTC1 fused to GFP (green fluorescent protein) revealed its co-localization with the V-H^+-PPase (vacuolar H^+-pyrophosphatase), a marker for acidocalcisomes. Western blot analysis of acidocalcisome fractions and immunogold electron microscopy using polyclonal antibodies against a fragment of TbVTC1 confirmed the acidocalcisome localization. Ablation of *TbVTC1* expression by RNA interference caused an abnormal morphology of acidocalcisomes, indicating that their biogenesis was disturbed, with a decreased pyrophosphate-driven H^+ uptake and Ca^{2+} content, a significant decrease in the amount of poly P and a deficient response to hyposmotic stress. Ablation of *TbVTC1* expression for longer periods produced marked gross morphological alterations compatible with a defect in cytokinesis, followed by cell death. Overexpression of the *TbVTC1* gene caused mild alterations in growth rate, but had no perceptible effect on acidocalcisome morphology. We propose that the PP_i-driven H^+ pumping deficiency induced by ablation of *TbVTC1* leads to alterations in the protonmotive force of acidocalcisomes, which results in deficient fusion or budding of the organelles, decreased H^+ and Ca^{2+} content, and decreased synthesis of poly P. A decrease in the poly P content would lead to osmotic sensitivity and defects in cytokinesis.

3.980 Peroxisomal-mitochondrial oxidation in a rodent model of obesity-associated insulin resistance

Noland, R.C. et al
Am. J. Physiol. Endocrinol. Metab., ***293***, *E986-E1001 (2007)*

Peroxisomal oxidation yields metabolites that are more efficiently utilized by mitochondria. This is of potential clinical importance because reduced fatty acid oxidation is suspected to promote excess lipid accumulation in obesity-associated insulin resistance. Our purpose was to assess peroxisomal contributions to mitochondrial oxidation in mixed gastrocnemius (MG), liver, and left ventricle (LV) homogenates from lean and fatty (*fa/fa*) Zucker rats. Results indicate that complete mitochondrial oxidation (CO_2 production) using various lipid substrates was increased approximately twofold in MG, unaltered in LV, and diminished ~50% in liver of *fa/fa* rats. In isolated mitochondria, malonyl-CoA inhibited CO_2 production from palmitate 78%, whereas adding isolated peroxisomes reduced inhibition to 21%. These data demonstrate that peroxisomal products may enter mitochondria independently of CPT I, thus providing a route to maintain lipid disposal under conditions where malonyl-CoA levels are elevated, such as in insulin-resistant tissues. Peroxisomal metabolism of lignoceric acid in *fa/fa* rats was elevated in both liver and MG (LV unaltered), but peroxisomal product distribution varied. A threefold elevation in incomplete oxidation was solely responsible for increased hepatic peroxisomal oxidation (CO_2 unaltered). Alternatively, only CO_2 was detected in MG, indicating that peroxisomal products were exclusively partitioned to mitochondria for complete lipid disposal. These data suggest tissue-specific destinations for peroxisome-derived products and emphasize a potential role for peroxisomes in skeletal muscle lipid metabolism in the obese, insulin-resistant state.

3.981 Anti–ß2-microglobulin monoclonal antibodies induce apoptosis in myeloma cells by recruiting MHC class I to and excluding growth and survival cytokine receptors from lipid rafts

Yang, J. et al
Blood, ***110(8)****, 3028-3035 (2007)*

We recently showed that monoclonal antibodies (mAbs) against $ß_2$-microglobulin ($ß_2$M) have a remarkably strong apoptotic effect on myeloma cells. The mAbs induced apoptosis by recruiting major histocompatibility complex (MHC) class I to lipid rafts, activated c-Jun N-terminal kinase (JNK), and inhibited phosphatidylinositol 3-kinase (PI3K)/Akt and extracellular signal–regulated kinase (ERK)

pathways. Growth and survival cytokines such as interleukin-6 (IL-6) and insulin-like growth factor-I (IGF-I), which could protect myeloma cells from dexamethasone-induced apoptosis, did not affect mAb-mediated cell death. This study was undertaken to elucidate the mechanisms underlying anti-ß$_2$M mAb–induced PI3K/Akt and ERK inhibition and the inability of IL-6 and IGF-I to protect myeloma cells from mAb-induced apoptosis. We focused on lipid rafts and confirmed that these membrane microdomains are required for IL-6 and IGF-I signaling. By recruiting MHC class I into lipid rafts, anti-ß$_2$M mAbs excluded IL-6 and IGF-I receptors and their substrates from the rafts. The mAbs not only redistributed the receptors in cell membrane, but also abrogated IL-6– or IGF-I–mediated Janus kinase/signal transducer and activator of transcription 3 (JAK/STAT3), PI3K/Akt, and Ras/Raf/ERK pathway signaling, which are otherwise constitutively activated in myeloma cells. Thus, this study further defines the tumoricidal mechanism of the mAbs and provides strong evidence to support the potential of these mAbs as therapeutic agents for myeloma.

3.982 **Protein kinase C-ε coimmunoprecipitates with cytochrome oxidase subunit IV and is associated with improved cytochrome-c oxidase activity and cardioprotection**
Guo, D. et al
Am. J. Physiol. Heart Circ. Physiol., ***293***, *H2219-H2230 (2007)*

We have utilized an in situ rat coronary ligation model to establish a PKC-ε cytochrome oxidase subunit IV (COIV) coimmunoprecipitation in myocardium exposed to ischemic preconditioning (PC). Ischemia-reperfusion (I/R) damage and PC protection were confirmed using tetrazolium-based staining methods and serum levels of cardiac troponin I. Homogenates prepared from the regions at risk (RAR) and not at risk (RNAR) for I/R injury were fractionated into cell-soluble (S), 600 *g* low-speed centrifugation (L), Percoll/**Optiprep** density gradient-purified mitochondrial (M), and 100,000 *g* particulate (P) fractions. COIV immunoreactivity and cytochrome-*c* oxidase activity measurements estimated the percentages of cellular mitochondria in S, L, M, and P fractions to be 0, 55, 29, and 16%, respectively. We observed 18, 3, and 3% of PKC-δ, -ε, and -ζ isozymes in the M fraction under basal conditions. Following PC, we observed a 61% increase in PKC-ε levels in the RAR M fraction compared with the RNAR M fraction. In RAR mitochondria, we also observed a 2.8-fold increase in PKC-ε serine 729 phosphoimmunoreactivity (autophosphorylation), indicating the presence of activated PKC-ε in mitochondria following PC. PC administered before prolonged I/R induced a 1.9-fold increase in the coimmunoprecipitation of COIV, with anti-PKC-ε antisera and a twofold enhancement of cytochrome-*c* oxidase activity. Our results suggest that PKC-ε may interact with COIV as a component of the cardioprotection in PC. Induction of this interaction may provide a novel therapeutic target for protecting the heart from I/R damage.

3.983 **HSP60 in heart failure: abnormal distribution and role in cardiac myocyte apoptosis**
Lin, L et al
Am. J. Physiol. Heart Circ. Physiol., ***293***, *H2238-H2247 (2007)*

Heat shock protein (HSP) 60 is a mitochondrial and cytosolic protein. Previously, we reported that HSP60 doubled in end-stage heart failure, even though levels of the protective HSP72 were unchanged. Furthermore, we observed that acute injury in adult cardiac myocytes resulted in movement of HSP60 to the plasma membrane. We hypothesized that the inflammatory state of heart failure would cause translocation of HSP60 to the plasma membrane and that this would provide a pathway for cardiac injury. Two models were used to test this hypothesis: *1*) a rat model of heart failure and *2*) human explanted failing hearts. We found that HSP60 localized to the plasma membrane and was also found in the plasma early in heart failure. Plasma membrane HSP60 localized to lipid rafts and was detectable on the cell surface with the use of both flow cytometry and confocal microscopy. Localization of HSP60 to the cell surface correlated with increased apoptosis. In heart failure, HSP60 is in the plasma membrane fraction, on the cell surface, and in the plasma. Membrane HSP60 correlated with increased apoptosis. Release of HSP60 may activate the innate immune system, promoting a proinflammatory state, including an increase in TNF-α. Thus abnormal trafficking of HSP60 to the cell surface may be an early trigger for myocyte loss and the progression of heart failure.

3.984 **Metabolism and short-term metabolic effects of conjugated linoleic acids in rat hepatocytes**
Priore, P., Giudetti, A.M., Natali, F., Gnoni, G.V. and Geelen, M.J.H.
Biochim. Biophys. Acta, ***1771(10)***, *1299-1307 (2007)*

Metabolic fate and short-term effects of a 1:1 mixture of *cis*-9,*trans*-11 and *trans*-10,*cis*-12-conjugated linoleic acids (CLA), compared to linoleic acid (LA), on lipid metabolism was investigated in rat liver. In

isolated mitochondria CLA-CoA were poorer substrates than LA-CoA for carnitine palmitoyltransferase-I (CPT-I) activity. However, in digitonin-permeabilized hepatocytes, where interactions among different metabolic pathways can be simultaneously investigated, CLA induced a remarkable stimulatory effect on CPT-I activity. This stimulation can be ascribed to a reduced malonyl-CoA level in turn due to inhibition of acetyl-CoA carboxylase (ACC) activity. The ACC/malonyl-CoA/CPT-I system can therefore represent a coordinate control by which CLA may exert effects on the partitioning of fatty acids between esterification and oxidation. Moreover, the rate of oxidation to CO_2 and ketone bodies was significantly higher from CLA; peroxisomes rather than mitochondria were responsible for this difference. Interestingly, peroxisomal acyl-CoA oxidase (AOX) activity strongly increased by CLA-CoA compared to LA-CoA. CLA, metabolized by hepatocytes at a higher rate than LA, were poorer substrates for cellular and VLDL-triacylglycerol (TAG) synthesis. Overall, our results suggest that increased fatty acid oxidation with consequent decreased fatty acid availability for TAG synthesis is a potential mechanism by which CLA reduce TAG level in rat liver.

3.985 Effect of hypoxia on the binding and subcellular distribution of iron regulatory proteins
Christova, T. and Templeton, D.M.
Mol. Cell. Biochem., ***301***, *21-32 (2007)*

Iron regulatory proteins 1 and 2 (IRP1, IRP2) are key determinants of uptake and storage of iron by the liver, and are responsive to oxidative stress and hypoxia potentially at the level of both protein concentration and mRNA-binding activity. We examined the effect of hypoxia (1% O_2) on IRP1 and IRP2 levels (Western blots) and mRNA-binding activity (gel shift assays) in human hepatoma HepG2 cells, and compared them with HEK 293 cells, a renal cell line known to respond to hypoxia. Total IRP binding to an iron responsive element (IRE) mRNA probe was increased several fold by hypoxia in HEK 293 cells, maximally at 4–8 h. An earlier and more modest increase (1.5- to 2-fold, peaking at 2 h and then declining) was seen in HepG2 cells. In both cell lines, IRP1 made a greater contribution to IRE-binding activity than IRP2. IRP1 protein levels were increased slightly by hypoxia in HEK 293 but not in HepG2 cells. IRP1 was distributed between cytosolic and membrane-bound fractions, and in both cells hypoxia increased both the amount and IRE-binding activity of the membrane-associated IRP1 fraction. Further density gradient fractionation of HepG2 membranes revealed that hypoxia caused an increase in total membrane IRP1, with a shift in the membrane-bound fraction from Golgi to an endoplasmic reticulum (ER)-enriched fraction. Translocation of IRP to the ER has previously been shown to stabilize transferrin receptor mRNA, thus increasing iron availability to the cell. Iron depletion with deferoxamine also caused an increase in ER-associated IRP1. Phorbol ester caused serine phosphorylation of IRP1 and increased its association with the ER. The calcium ionophore ionomycin likewise increased ER-associated IRP1, without affecting total IRE-binding activity. We conclude that IRP1 is translocated to the ER by multiple signals in HepG2 cells, including hypoxia, thereby facilitating its role in regulation of hepatic gene expression.

3.986 Release of thioredoxin from Saccharomyces cerevisiae with environmental stimuli: solubilization of thioredoxin with ethanol
Takeuchi, Y. et al
Appl. Microbiol. Biotechnol., ***75***, *1393-1399 (2007)*

Thioredoxin is crucial for the maintenance of the redox status of cells of all types. Mammalian thioredoxin is secreted from various types of cells, although the mechanism underlying has not yet been clarified. Previously, we demonstrated that thioredoxin was released from *Saccharomyces cerevisiae* after treatment with ethanol. In this paper, we show that as well as ethanol, low-pH shock and hypoosmotic shock release thioredoxin. Low-molecular-weight proteins in yeast cells were preferentially released by treatment with ethanol and low-pH shock. A cell wall integrity pathway seems partially involved in the hypoosmotic shock-induced release of thioredoxin. Considerable amounts of thioredoxin were present in the insoluble fractions of the cells, a portion of which was associated with lipid microdomains that are resistant to nonionic detergent at 4°C. The intracellular localization of thioredoxin may influence the efficiency of its release from yeast cells with ethanol.

3.987 Flagellar membrane trafficking in kinetoplastids
Fridberg, A., Buchanan, K.T. and Engman, D.M.

This review was presented at the International Symposium on Vesicle Trafficking in Parasitic Protozoa at Caxambu, Brasil, in November, 2005.

3.988 Influence of lipid rafts on CD1d presentation by dendritic cells
Peng, W. et al
Mol. Membrane Biol., ***24(5-6)***, *475-484 (2007)*

Our main objective was to analyze the role of lipid rafts in the activation of Vα-14$^-$ and Vα-14$^+$ T hybridomas by dendritic cells. We showed that activation of Vα-14$^+$ hybridomas by dendritic cells or other CD1d-expressing cells was altered by disruption of lipid rafts with the cholesterol chelator MβCD. However, CD1d presentation to autoreactive Vα-14$^-$ anti-CD1d hybridomas which do not require the endocytic pathway was not altered. Using partitioning of membrane fractions with Brij98 at 37°C, we confirmed that CD1d was enriched in subcellular fractions corresponding to lipid rafts and we describe that α-GalCer enhanced CD1d amount in the low density detergent insoluble fraction. We conclude that the membrane environment of CD1d can influence antigen presentation mainly when the endocytic pathway is required. Flow cytometry analysis can provide additional information on lipid rafts in plasma membranes and allows a dynamics follow-up of lipid rafts partitioning. Using this method, we showed that CD1d plasma membrane expression was sensitive to low concentrations of detergent. This may suggest either that CD1d is associated with lipid rafts mainly in intracellular membranes or that its association with the lipid rafts in the plasma membrane is weak.

3.990 Plasma Membrane Proteomics
Alexandersson, E., Gustavsson, N., Bernfur, K., Kjellbom, P. and Larsson, C.
Plant Proteomics, Springer Berlin/Heidelberg, 189-206 (2007)

Proteins residing in the plasma membrane have key functions in transport, signal transduction, vesicle trafficking and many other important processes. To better understand these processes it is necessary to reveal the identity of plasma membrane proteins and to monitor modifications and regulation of their expression. This chapter is an overview of the methods used in plant plasma membrane proteomic studies and the results obtained so far. It focuses on studies using mass spectrometry for identification and includes aspects of plasma membrane fractionation, extraction and washing treatments, assessment of purity, separation methods for plasma membrane proteins and choice of techniques for protein cleavage. Finally, the results of plasma membrane proteomic studies are compared and problems with contaminating proteins are discussed.

3.991 CD44 Regulates Hepatocyte Growth Factor-mediated Vascular Integrity: ROLE OF c-Met, Tiam1/Rac1, DYNAMIN 2, AND CORTACTIN
Singleton, P.A. et al
J. Biol. Chem., ***282(42)***, *30643-30657 (2007)*

The preservation of vascular endothelial cell (EC) barrier integrity is critical to normal vessel homeostasis, with barrier dysfunction being a feature of inflammation, tumor angiogenesis, atherosclerosis, and acute lung injury. Therefore, agents that preserve or restore vascular integrity have important therapeutic implications. In this study, we explored the regulation of hepatocyte growth factor (HGF)-mediated enhancement of EC barrier function via CD44 isoforms. We observed that HGF promoted c-Met association with CD44v10 and recruitment of c-Met into caveolin-enriched microdomains (CEM) containing CD44s (standard form). Treatment of EC with CD44v10-blocking antibodies inhibited HGF-mediated c-Met phosphorylation and c-Met recruitment to CEM. Silencing CD44 expression (small interfering RNA) attenuated HGF-induced recruitment of c-Met, Tiam1 (a Rac1 exchange factor), cortactin (an actin cytoskeletal regulator), and dynamin 2 (a vesicular regulator) to CEM as well as HGF-induced

trans-EC electrical resistance. In addition, silencing Tiam1 or dynamin 2 reduced HGF-induced Rac1 activation, cortactin recruitment to CEM, and EC barrier regulation. We observed that both HGF- and high molecular weight hyaluronan (CD44 ligand)-mediated protection from lipopolysaccharide-induced pulmonary vascular hyperpermeability was significantly reduced in CD44 knock-out mice, thus validating these *in vitro* findings in an *in vivo* murine model of inflammatory lung injury. Taken together, these results suggest that CD44 is an important regulator of HGF/c-Met-mediated *in vitro* and *in vivo* barrier enhancement, a process with essential involvement of Tiam1, Rac1, dynamin 2, and cortactin.

3.992 **A reversible form of lysine acetylation in the ER and Golgi lumen controls the molecular stabilization of BACE1**
Costantini, C., Ko, M.H., Cabell, M., Jonas, M.C. and Puglielli, L.
Biochem. J., ***407***, *383-395 (2007)*

The lipid second messenger ceramide regulates the rate of β cleavage of the Alzheimer's disease APP (amyloid precursor protein) by affecting the molecular stability of the β secretase BACE1 (β-site APP cleaving enzyme 1). Such an event is stimulated in the brain by the normal process of aging, and is under the control of the general aging programme mediated by the insulin-like growth factor 1 receptor. In the present study we report that BACE1 is acetylated on seven lysine residues of the N-terminal portion of the nascent protein. This process involves lysine acetylation in the lumen of the ER (endoplasmic reticulum) and is followed by deacetylation in the lumen of the Golgi apparatus, once the protein is fully mature. We also show that specific enzymatic activities acetylate (in the ER) and deacetylate (in the Golgi apparatus) the lysine residues. This process requires carrier-mediated translocation of acetyl-CoA into the ER lumen and is stimulated by ceramide. Site-directed mutagenesis indicates that lysine acetylation is necessary for nascent BACE1 to leave the ER and move ahead in the secretory pathway, and for the molecular stabilization of the protein.

3.993 **A Functional Dynein–Microtubule Network Is Required for NGF Signaling Through the Rap1/MAPK Pathway**
Wu, C. et al
Traffic, ***8***, *1503-1520 (2007)*

Rap1 transduces nerve growth factor (NGF)/tyrosine receptor kinase A (TrkA) signaling in early endosomes, leading to sustained activation of the p44/p42 mitogen-activated protein kinases (MAPK1/2). However, the mechanisms by which NGF, TrkA and Rap1 are trafficked to early endosomes are poorly defined. We investigated trafficking and signaling of NGF, TrkA and Rap1 in PC12 cells and in cultured rat dorsal root ganglion (DRG) neurons. Herein, we show a role for both microtubule- and dynein-based transport in NGF signaling through MAPK1/2. NGF treatment resulted in trafficking of NGF, TrkA and Rap1 to early endosomes in the perinuclear region of PC12 cells where sustained activation of MAPK1/2 was observed. Disruption of microtubules with nocodazole in PC12 cells had no effect on the activation of TrkA and Ras. However, it disrupted intracellular trafficking of TrkA and Rap1. Moreover, NGF-induced activation of Rap1 and sustained activation of MAPK1/2 were markedly suppressed. Inhibition of dynein activity through overexpression of dynamitin (p50) blocked trafficking of Rap1 and the sustained phase of MAPK1/2 activation in PC12 cells. Remarkably, even in the continued presence of NGF, mature DRG neurons that overexpressed p50 became atrophic and most (>80%) developing DRG neurons died. Dynein- and microtubule-based transport is thus necessary for TrkA signaling to Rap1 and MAPK1/2.

3.994 **Angiotensin II Decreases Glucose Uptake by Downregulation of GLUT1 in the Cell Membrane of the Vascular Smooth Muscle Cell Line A10**
Masori, M. et al
J. Cardiovasc. Pharmacol., ***50(3)***, *267-273 (2007)*

Recent evidence suggests a crosstalk between angiotensin II (Ang II) and insulin. However, whether this crosstalk affects glucose uptake, particularly in terms of actin filament involvement, has not yet been studied in vascular smooth muscle cells. Pretreatment of cells with either Ang II or cytochalasin D disarranged actin filaments in a time-dependent manner and inhibited glucose uptake. However, insulin increased actin reorganization and glucose uptake. Membrane fractionation studies showed that Ang II decreased GLUT-1 at the cell membrane, whereas it increased GLUT-1 in the cytoplasm, indicating that Ang II may cause internalization of GLUT-1 via actin disorganization, consequently decreasing glucose uptake. The effects of Ang II on glucose uptake and actin reorganization were blocked by AT1 receptor antagonist, but not by AT2 antagonist. Either P38 or ERK1/2 inhibitors partially reversed the Ang II-

inhibited actin reorganization and glucose uptake, suggesting that MAPK signaling pathways could be involved as downstream events in Ang II signaling, and this signaling may interfere with insulin-induced actin reorganization and glucose uptake. These data imply that Ang II induces insulin resistance by decreasing glucose uptake via disarrangement of actin filaments, which provides a novel insight into understanding of insulin resistance by Ang II at the molecular level.

3.995 BK Channels Are Linked to Inositol 1,4,5-Triphosphate Receptors via Lipid Rafts: A NOVEL MECHANISM FOR COUPLING [Ca2+]i TO ION CHANNEL ACTIVATION
Weaver, A.K., Olsen, M.L., McFerrin, M.B. and Southeimer, H.
J. Biol. Chem., ***282(43)***, *31558-31568 (2007)*

Glioma cells prominently express a unique splice variant of a large conductance, calcium-activated potassium channel (BK channel). These channels transduce changes in intracellular calcium to changes of K^+ conductance in the cells and have been implicated in growth control of normal and malignant cells. The Ca^{2+} increase that facilitates channel activation is thought to occur via activation of intracellular calcium release pathways or influx of calcium through Ca^{2+}-permeable ion channels. We show here that BK channel activation involves the activation of inositol 1,4,5-triphosphate receptors (IP_3R), which localize near BK channels in specialized membrane domains called lipid rafts. Disruption of lipid rafts with methyl-β-cyclodextrin disrupts the functional association of BK channel and calcium source resulting in a >50% reduction in K^+ conductance mediated by BK channels. The reduction of BK current by lipid raft disruption was overcome by the global elevation of intracellular calcium through inclusion of 750 nM Ca^{2+} in the pipette solution, indicating that neither the calcium sensitivity of the channel nor their overall number was altered. Additionally, pretreatment of glioma cells with 2-aminoethoxydiphenyl borate to inhibit IP_3Rs negated the effect of methyl-β-cyclodextrin, providing further support that IP_3Rs are the calcium source for BK channels. Taken together, these data suggest a privileged association of BK channels in lipid raft domains and provide evidence for a novel coupling of these Ca^{2+}-sensitive channels to their second messenger source.

3.996 Escherichia coli Signal Recognition Particle Receptor FtsY Contains an Essential and Autonomous Membrane-binding Amphipathic Helix
Parlitz, R. et al
J. Biol. Chem., ***282(44)***, *32176-32184 (2007)*

Escherichia coli membrane protein biogenesis is mediated by a signal recognition particle and its membrane-associated receptor (FtsY). Although crucial for its function, it is still not clear how FtsY interacts with the membrane. Analysis of the structure/function differences between severely truncated active (NG+1) and inactive (NG) mutants of FtsY enabled us to identify an essential membrane-interacting determinant. Comparison of the three-dimensional structures of the mutants, combined with site-directed mutagenesis, modeling, and liposome-binding assays, revealed that FtsY contains a conserved autonomous lipid-binding amphipathic α-helix at the N-terminal end of the N domain. Deletion experiments showed that this helix is essential for FtsY function *in vivo*, thus offering, for the first time, clear evidence for the functionally important, physiologically relevant interaction of FtsY with lipids.

3.997 Saccharomyces cerevisiae CWH43 Is Involved in the Remodeling of the Lipid Moiety of GPI Anchors to Ceramides
Umemura, M., Fujita, M., Yoko-o., T., Fukamizu, A. and Jigami, Y.
Mol. Biol. Cell, ***18***, *4304-4316 (2007)*

The glycosylphosphatidylinositol (GPI)-anchored proteins are subjected to lipid remodeling during their biosynthesis. In the yeast *Saccharomyces cerevisiae*, the mature GPI-anchored proteins contain mainly ceramide or diacylglycerol with a saturated long-fatty acid, whereas conventional phosphatidylinositol (PI) used for GPI biosynthesis contains an unsaturated fatty acid. Here, we report that *S. cerevisiae* Cwh43p, whose N-terminal region contains a sequence homologous to mammalian PGAP2, is involved in the remodeling of the lipid moiety of GPI anchors to ceramides. In *cwh43* disruptant cells, the PI moiety of the GPI-anchored protein contains a saturated long fatty acid and lyso-PI but not inositolphosphorylceramides, which are the main lipid moieties of GPI-anchored proteins from wild-type cells. Moreover, the C-terminal region of Cwh43p (Cwh43-C), which is not present in PGAP2, is essential for the ability to remodel GPI lipids to ceramides. The N-terminal region of Cwh43p (Cwh43-N) is associated with Cwh43-C, and it enhanced the lipid remodeling to ceramides by Cwh43-C. Our results also indicate that mouse FRAG1 and C130090K23, which are homologous to Cwh43-N and -C, respectively, share these activities.

3.998 A novel beta-site amyloid precursor protein cleaving enzyme (BACE) isoform regulated by nonsense-mediated mRNA decay and proteasome-dependent degradation
Tanahashi, H. and Tabira, T.
Neurosci. Lett., ***428***, *103-108 (2007)*

Proteolytic cleavage of amyloid beta-peptide (Aβ) from amyloid precursor protein (APP) is a key event in the pathogenesis of Alzheimer's disease. Beta-site amyloid precursor protein cleaving enzyme (BACE) cleaves the APP at the N-terminus of Aβ. We investigated whether particular stress conditions modify the expression and activity of BACE, and found that treatment of human neuroblastoma cells with protein synthesis inhibitors induced expression of a novel splice variant of BACE. This unusual transcript, I-127, is produced by usage of an internal splicing donor site in exon 3. The splicing event leads to a premature termination codon, as well as elimination of one of two conserved aspartic protease active sites, a transmembrane domain, and a C-terminal cytoplasmic tail from BACE. Low levels of this mRNA were found in the human brain. When expressed in cells, I-127 had no effect on Aβ secretion and was retained in the endoplasmic reticulum without propeptide removal. It was also unstable with a turnover $t_{1/2}$ of ~ 2 h; normal BACE had a turnover $t_{1/2}$ of ~8 h. Finally, I-127 was degraded in a proteasome-dependent manner. Thus, I-127 is regulated by both nonsense-mediated mRNA decay (NMD) and proteasome-dependent degradation.

3.999 Plant organelle proteomics
Lilley, K.S. and Dupree, P.
Current Opinion in Plant Biol., ***10***, *594-599 (2007)*

It is important for cell biologists to know the subcellular localization of proteins to understand fully the functions of organelles and the compartmentation of plant metabolism. The accurate description of an organelle proteome requires the ability to identify genuine protein residents. Such accurate assignment is difficult in situations where a pure homogeneous preparation of the organelle cannot be achieved. Practical limitations in both organelle isolation and also analysis of low abundance proteins have resulted in limited datasets from high throughput proteomics approaches. Here, we discuss some examples of quantitative proteomic methods and their use to study plant organelle proteomes, with particular reference to methods designed to give unequivocal assignments to organelles.

3.1000 Comparison of the contributions of the nuclear and cytoplasmic compartments to global gene expression in human cells
Barthelson, R.A., Lambert, G.M., Vanier, C., Lynch, R.M. and Galbraith, D.W.
BMC Genomics, ***8(340),*** *1-15 (2007)*

Background
In the most general sense, studies involving global analysis of gene expression aim to provide a comprehensive catalog of the components involved in the production of recognizable cellular phenotypes. These studies are often limited by the available technologies. One technology, based on microarrays, categorizes gene expression in terms of the abundance of RNA transcripts, and typically employs RNA prepared from whole cells, where cytoplasmic RNA predominates.
Results
Using microarrays comprising oligonucleotide probes that represent either protein-coding transcripts or microRNAs (miRNA), we have studied global transcript accumulation patterns for the HepG2 (human hepatoma) cell line. Through subdividing the total pool of RNA transcripts into samples from nuclei, the cytoplasm, and whole cells, we determined the degree of correlation of these patterns across these different subcellular locations. The transcript and miRNA abundance patterns for the three RNA fractions were largely similar, but with some exceptions: nuclear RNA samples were enriched with respect to the cytoplasm in transcripts encoding proteins associated with specific nuclear functions, such as the cell cycle, mitosis, and transcription. The cytoplasmic RNA fraction also was enriched, when compared to the nucleus, in transcripts for proteins related to specific nuclear functions, including the cell cycle, DNA replication, and DNA repair. Some transcripts related to the ubiquitin cycle, and transcripts for various membrane proteins were sorted into either the nuclear or cytoplasmic fractions.
Conclusion
Enrichment or compartmentalization of cell cycle and ubiquitin cycle transcripts within the nucleus may be related to the regulation of their expression, by preventing their translation to proteins. In this way, these cellular functions may be tightly controlled by regulating the release of mRNA from the nucleus and

thereby the expression of key rate limiting steps in these pathways. Many miRNA precursors were also enriched in the nuclear samples, with significantly fewer being enriched in the cytoplasm. Studies of mRNA localization will help to clarify the roles RNA processing and transport play in the regulation of cellular function.

3.1001 Integral and Associated Lysosomal Membrane Proteins
Schröder, B. et al
Traffic, ***8(12)***, *1676-1686 (2007)*

We searched for novel proteins in lysosomal membranes, tentatively participating in molecular transport across the membrane and/or in interactions with other compartments. In membranes purified from placental lysosomes, we identified 58 proteins, known to reside at least partially in the lysosomal membrane. These included 17 polypeptides comprising or associated with the vacuolar adenosine triphosphatase. We report on additional 86 proteins that were significantly enriched in the lysosomal membrane fraction. Among these, 12 novel proteins of unknown functions were found. Three were orthologues of rat proteins that have been identified in tritosomes by Bagshaw RD et al. (A proteomic analysis of lysosomal integral membrane proteins reveals the diverse composition of the organelle. Mol Cell Proteomics 2005;4:133–143). Here, the proteins encoded by LOC201931 (FLJ38482) and LOC51622 (C7orf28A) were expressed with an appended fluorescent tag in HeLa cells and found to be present in lysosomal organelles. Among the lysosomally enriched proteins, also 16 enzymes and transporters were detected that had not been assigned to lysosomal membranes previously. Finally, our results identified a particular set of proteins with known functions in signaling and targeting to be at least partially associated with lysosomes.

3.1002 Function and dynamics of PKD2 in Chlamydomonas reinhardtii flagella
Huang, K. et al
J. Cell Biol., ***179(3)***, *501-514 (2007)*

To analyze the function of ciliary polycystic kidney disease 2 (PKD2) and its relationship to intraflagellar transport (IFT), we cloned the gene encoding *Chlamydomonas reinhardtii* PKD2 (CrPKD2), a protein with the characteristics of PKD2 family members. Three forms of this protein (210, 120, and 90 kD) were detected in whole cells; the two smaller forms are cleavage products of the 210-kD protein and were the predominant forms in flagella. In cells expressing CrPKD2-GFP, about 10% of flagellar CrPKD2-GFP was observed moving in the flagellar membrane. When IFT was blocked, fluorescence recovery after photobleaching of flagellar CrPKD2-GFP was attenuated and CrPKD2 accumulated in the flagella. Flagellar CrPKD2 increased fourfold during gametogenesis, and several *CrPKD2* RNA interference strains showed defects in flagella-dependent mating. These results suggest that the CrPKD2 cation channel is involved in coupling flagellar adhesion at the beginning of mating to the increase in flagellar calcium required for subsequent steps in mating.

3.1003 SorLA/LR11 Regulates Processing of Amyloid Precursor Protein via Interaction with Adaptors GGA and PACS-1
Schmidt, V. et al
J. Biol. Chem., ***282(45)***, *32956-32964 (2007)*

SorLA has been recognized as a novel sorting receptor that regulates trafficking and processing of the amyloid precursor protein (APP) and that represents a significant risk factor for sporadic Alzheimer disease. Here, we investigated the cellular mechanisms that control intracellular trafficking of sorLA and their relevance for APP processing. We demonstrate that sorLA acts as a retention factor for APP in trans-Golgi compartments/trans-Golgi network, preventing release of the precursor into regular processing pathways. Proper localization and activity of sorLA are dependent on functional interaction with GGA and PACS-1, adaptor proteins involved in protein transport to and from the trans-Golgi network. Aberrant targeting of sorLA to the recycling compartment or the plasma membrane causes faulty APP trafficking and imbalance in non-amyloidogenic and amyloidogenic processing fates. Thus, our findings identified altered routing of sorLA as a major cellular mechanism contributing to abnormal APP processing and enhanced amyloid β-peptide formation.

3.1004 Myristoylation Is Required for Human Immunodeficiency Virus Type 1 Gag-Gag Multimerization in Mammalian Cells
Li, H., Dou, J., Ding, L. and Spearman, P.

J. Virol., ***81(23)***, *12899-12910 (2007)*

The Gag protein of human immunodeficiency virus type 1 directs the virion assembly process. Gag proteins must extensively multimerize during the formation of the spherical immature virion shell. In vitro, virus-like particles can be generated from Gag proteins that lack the N-terminal myristic acid modification or the nucleocapsid (NC) protein. The precise requirements for Gag-Gag multimerization under conditions present in mammalian cells, however, have not been fully elucidated. In this study, a Gag-Gag multimerization assay measuring fluorescence resonance energy transfer was employed to define the Gag domains that are essential for homomultimerization. Three essential components were identified: protein-protein interactions contributed by residues within both the N- and C-terminal domains of capsid (CA), basic residues in NC, and the presence of myristic acid. The requirement of myristic acid for multimerization was reproduced using the heterologous myristoylation sequence from v-*src*. Only when a leucine zipper dimerization motif was placed in the position of NC was a nonmyristoylated Gag protein able to multimerize. These results support a three-component model for Gag-Gag multimerization that includes membrane interactions mediated by the myristoylated N terminus of Gag, protein-protein interactions between CA domains, and NC-RNA interactions.

3.1005 Induction of Epidermal Growth Factor Receptor Expression by Epstein-Barr Virus Latent Membrane Protein 1 C-Terminal-Activating Region 1 Is Mediated by NF-κB p50 Homodimer/Bcl-3 Complexes

Thornburg, N.J. and Raab-Traub, N.
J. Virol., ***81(23)***, *12954-12961 (2007)*

The Epstein-Barr virus (EBV) is associated with the development of numerous malignancies, including the epithelial malignancy nasopharyngeal carcinoma (NPC). The viral oncoprotein latent membrane protein 1 (LMP1) is expressed in almost all EBV-associated malignancies and has profound effects on gene expression. LMP1 acts as a constitutively active tumor necrosis factor receptor and activates multiple forms of the NF-κB family of transcription factors. LMP1 has two domains that both activate NF-κB. In epithelial cells, LMP1 C-terminal activating region 1 (CTAR1) uniquely activates p50/p50-, p50/p52-, and p65-containing complexes while CTAR2 activates canonical p50/p65 complexes. CTAR1 also uniquely upregulates the epidermal growth factor receptor (EGFR). In NPC, NF-κB p50/p50 homodimers and the transactivator Bcl-3 were detected on the EGFR promoter. In this study, the role of NF-κB p50 and Bcl-3 in LMP1-mediated upregulation of EGFR was analyzed. In LMP1-CTAR1-expressing cells, chromatin immunoprecipitation detected p50 and Bcl-3 on the NF-κB consensus sites within the *egfr* promoter. Transient overexpression of p50 and Bcl-3 increased EGFR expression, confirming the regulation of EGFR by these factors. Treatment with p105/p50 siRNA effectively reduced p105/p50 levels but unexpectedly increased Bcl-3 expression and levels of p50/Bcl-3 complexes, resulting in increased EGFR expression. These data suggest that induction of p50/p50/Bcl-3 complexes by LMP1 CTAR1 mediates LMP1-induced EGFR upregulation and that formation of the p50/p50/Bcl-3 complex is negatively regulated by the p105 precursor. The distinct forms of NF-κB that are induced by LMP1 CTAR1 likely activate distinct cellular genes.

3.1006 Human Immunodeficiency Virus Type 1 Nef protein modulates the lipid composition of virions and host cell membrane microdomains

Brügger, B. et al
Retrovirology, ***4(70)***, *1-12*

Background
The Nef protein of Human Immunodeficiency Viruses optimizes viral spread in the infected host by manipulating cellular transport and signal transduction machineries. Nef also boosts the infectivity of HIV particles by an unknown mechanism. Recent studies suggested a correlation between the association of Nef with lipid raft microdomains and its positive effects on virion infectivity. Furthermore, the lipidome analysis of HIV-1 particles revealed a marked enrichment of classical raft lipids and thus identified HIV-1 virions as an example for naturally occurring membrane microdomains. Since Nef modulates the protein composition and function of membrane microdomains we tested here if Nef also has the propensity to alter microdomain lipid composition.
Results
Quantitative mass spectrometric lipidome analysis of highly purified HIV-1 particles revealed that the presence of Nef during virus production from T lymphocytes enforced their raft character via a significant reduction of polyunsaturated phosphatidylcholine species and a specific enrichment of sphingomyelin. In

contrast, Nef did not significantly affect virion levels of phosphoglycerolipids or cholesterol. The observed alterations in virion lipid composition were insufficient to mediate Nef's effect on particle infectivity and Nef augmented virion infectivity independently of whether virus entry was targeted to or excluded from membrane microdomains. However, altered lipid compositions similar to those observed in virions were also detected in detergent-resistant membrane preparations of virus producing cells.
Conclusion
Nef alters not only the proteome but also the lipid composition of host cell microdomains. This novel activity represents a previously unrecognized mechanism by which Nef could manipulate HIV-1 target cells to facilitate virus propagation in vivo.

3.1007 Caveolins and intracellular calcium regulation in human airway smooth muscle
Prakash, Y.S. et al
Am. J. Physiol. Lung Cell Mol. Physiol., ***293***, *L1118-L1126 (2007)*

Regulation of intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) is a key factor in airway smooth muscle (ASM) tone. In vascular smooth muscle, specialized membrane microdomains (caveolae) expressing the scaffolding protein caveolin-1 are thought to facilitate cellular signal transduction. In human ASM cells, we tested the hypothesis that caveolae mediate Ca^{2+} responses to agonist stimulation. Fluorescence immunocytochemistry with confocal microscopy, as well as Western blot analysis, was used to determine that agonist receptors (M_3 muscarinic, bradykinin, and histamine) and store-operated Ca^{2+} entry (SOCE)-regulatory mechanisms colocalize with caveolin-1. Although caveolin-2 coexpressed with caveolin-1, caveolin-3 was absent. In fura 2-loaded ASM cells, $[Ca^{2+}]_i$ responses to 1 μM ACh, 10 μM histamine, and 10 nM bradykinin, as well as SOCE, were attenuated (each to a different extent) after disruption of caveolae by the cholesterol-chelating drug methyl-β-cyclodextrin. Transfection of ASM cells with 50 nM caveolin-1 small interfering RNA significantly weakened caveolin-1 expression and blunted $[Ca^{2+}]_i$ responses to bradykinin and histamine, as well as SOCE, but the response to ACh was less intense. These results indicate that caveolae are present in ASM and that caveolin-1 contributes to regulation of $[Ca^{2+}]_i$ responses to agonist.

3.1008 Mitochondrial P450-dependent arachidonic acid metabolism by TCDD-induced hepatic CYP1A5; conversion of EETs to DHETs by mitochondrial soluble epoxide hydrolase
Labitzke, E.M., Diani-Moore, S. and Rifkind, A.B.
Arch. Biochem. Biophys., ***468***, *70-81 (2007)*

Several P450 enzymes localized in the endoplasmic reticulum and thought to be involved primarily in xenobiotic metabolism, including mouse and rat CYP1A1 and mouse CYP1A2, have also been found to translocate to mitochondria. We report here that the environmental toxin 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) induces enzymatically active CYP1A4/1A5, the avian orthologs of mammalian CYP1A1/1A2, in chick embryo liver mitochondria as well as in microsomes. P450 proteins and activity levels (CYP1A4-dependent 7-ethoxyresorufin-*O*-deethylase and CYP1A5-dependent arachidonic acid epoxygenation) in mitochondria were 23–40% of those in microsomes. DHET formation by mitochondria was twice that of microsomes and was attributable to a mitochondrial soluble epoxide hydrolase as confirmed by Western blotting with antiEPHX2, conversion by mitochondria of pure 11,12 and 14,15-EET to the corresponding DHETs and inhibition of DHET formation by the soluble epoxide hydrolase inhibitor, 12(-3-adamantan-1-yl-ureido)-dodecanoic acid (AUDA). TCDD also suppressed formation of mitochondrial and microsomal 20-HETE. The findings newly identify mitochondria as a site of P450-dependent arachidonic acid metabolism and as a potential target for TCDD effects. They also demonstrate that mitochondria contain soluble epoxide hydrolase and underscore a role for CYP1A in endobiotic metabolism.

3.1009 Improved subcellular fractionation of the heavy mitochondria pellet using Free Flow Electrophoresis system
Aboldzade-Bavil, A. et al
Mitochondrion, ***7****, 419 (2007)*

The preparative dissection of cells into their substructure reduces sample complexity and facilitates functional analysis of proteins in a physiological context. According to the high morphological variability of many subcellular compartments, however, cells inhabit different organellar subpopulations supposed to be linked to specialized biological functions or developmental stages. A prerequisite for a fundamental

characterization of these organellar subpopulations on the proteome level are highly pure fractions, which could not be obtained by classical separation technologies. We developed a workflow for the subcellular fractionation of the heavy mitochondria pellet using the BD Free Flow Electrophoresis system (FFE). The FFE methodology relies on the net charge of the organelles to be separated, which is caused by protein domains extending from the membrane surface. According to charge and size, particles are deflected differently in an electric field and are separated through a buffer flow perpendicular to the electric field. With this technique a second dimension separation step, relying on physical parameters not utilized in centrifugation techniques, was added to the workflow. Successful isolations of various cellular structures have been obtained by the use of this workflow. For this reason we invented FFE as an additional purification step to purify a 2.860 g fraction of rat liver tissue which mainly contained heavy mitochondria but also peroxisomes and lysosomes, so called ''high density peroxisomes and lysosomes''. The resulting pellet was loaded on an Optiprep gradient. Thereafter, each density gradient fraction was subjected to FFE. Using this workflow we were able to purify various subcellular fractions. To validate the purity and integrity of sub-fractions we performed enzyme assays for organellar markers and immunoblots with specific antibodies as well as electron microscopy. The subcellular fractionation using the FFE-system indicated that the purification was selective on the organelle level documenting the suitability of this separation technique in proteomic research.

3.1010 Identification of SVIP as an Endogenous Inhibitor of Endoplasmic Reticulum-associated Degradation

Ballar, P. et al

J. Biol. Chem., ***282(47)***, *33908-33914 (2007)*

Misfolded proteins in the endoplasmic reticulum (ER) are eliminated by a process known as ER-associated degradation (ERAD), which starts with misfolded protein recognition, followed by ubiquitination, retrotranslocation to the cytosol, deglycosylation, and targeting to the proteasome for degradation. Actions of multisubunit protein machineries in the ER membrane integrate these steps. We hypothesized that regulation of the multisubunit machinery assembly is a mechanism by which ERAD activity is regulated. To test this hypothesis, we investigated the potential regulatory role of the small p97/VCP-interacting protein (SVIP) on the formation of the ERAD machinery that includes ubiquitin ligase gp78, AAA ATPase p97/VCP, and the putative channel Derlin1. We found that SVIP is anchored to microsomal membrane via myristoylation and co-fractionated with gp78, Derlin1, p97/VCP, and calnexin to the ER. Like gp78, SVIP also physically interacts with p97/VCP and Derlin1. Overexpression of SVIP blocks unassembled CD3δ from association with gp78 and p97/VCP, which is accompanied by decreases in CD3δ ubiquitination and degradation. Silencing SVIP expression markedly enhances the formation of gp78-p97/VCP-Derlin1 complex, which correlates with increased degradation of CD3δ and misfolded Z variant of α-1-antitrypsin, established substrates of gp78. These results suggest that SVIP is an endogenous inhibitor of ERAD that acts through regulating the assembly of the gp78-p97/VCP-Derlin1 complex.

3.1011 The Confluence-dependent Interaction of Cytosolic Phospholipase A2-α with Annexin A1 Regulates Endothelial Cell Prostaglandin E2 Generation

Herbert, S.P., Odell, A.F., Ponnambalam, S. and walker, J.H.

J. Biol. Chem., ***282(47)***, *3468-3478 (2007)*

The regulated generation of prostaglandins from endothelial cells is critical to vascular function. Here we identify a novel mechanism for the regulation of endothelial cell prostaglandin generation. Cytosolic phospholipase A_2-α (cPLA$_2\alpha$) cleaves phospholipids in a Ca^{2+}-dependent manner to yield free arachidonic acid and lysophospholipid. Arachidonic acid is then converted into prostaglandins by the action of cyclooxygenase enzymes and downstream synthases. By previously undefined mechanisms, nonconfluent endothelial cells generate greater levels of prostaglandins than confluent cells. Here we demonstrate that Ca^{2+}-independent association of cPLA$_2\alpha$ with the Golgi apparatus of confluent endothelial cells correlates with decreased prostaglandin synthesis. Golgi association blocks arachidonic acid release and prevents functional coupling between cPLA$_2\alpha$ and COX-mediated prostaglandin synthesis. When inactivated at the Golgi apparatus of confluent endothelial cells, cPLA$_2\alpha$ is associated with the phospholipid-binding protein annexin A1. Furthermore, the siRNA-mediated knockdown of endogenous annexin A1 significantly reverses the inhibitory effect of confluence on endothelial cell prostaglandin generation. Thus the confluence-dependent interaction of cPLA$_2\alpha$ and annexin A1 at the Golgi acts as a novel molecular switch controlling cPLA$_2\alpha$ activity and endothelial cell prostaglandin generation.

3.1012 **The Nuclear RhoA Exchange Factor Net1 Interacts with Proteins of the Dlg Family, Affects Their Localization, and Influences Their Tumor Suppressor Activity**
Garcia-Mata, R. et al
Mol. Cell. Biol., ***27(24)***, *8683-8697 (2007)*

Net1 is a RhoA-specific guanine nucleotide exchange factor which localizes to the nucleus at steady state. A deletion in its N terminus redistributes the protein to the cytosol, where it activates RhoA and can promote transformation. Net1 contains a PDZ-binding motif at the C terminus which is essential for its transformation properties. Here, we found that Net1 interacts through its PDZ-binding motif with tumor suppressor proteins of the Dlg family, including Dlg1/SAP97, SAP102, and PSD95. The interaction between Net1 and its PDZ partners promotes the translocation of the PDZ proteins to nuclear subdomains associated with PML bodies. Interestingly, the oncogenic mutant of Net1 is unable to shuttle the PDZ proteins to the nucleus, although these proteins still associate as clusters in the cytosol. Our results suggest that the ability of oncogenic Net1 to transform cells may be in part related to its ability to sequester tumor suppressor proteins like Dlg1 in the cytosol, thereby interfering with their normal cellular function. In agreement with this, the transformation potential of oncogenic Net1 is reduced when it is coexpressed with Dlg1 or SAP102. Together, our results suggest that the interaction between Net1 and Dlg1 may contribute to the mechanism of Net1-mediated transformation.

3.1013 **Endocytic Trafficking of Sphingomyelin Depends on Its Acyl Chain Length**
Koivusalo, M., Jansen, M., Somerharju, P and Ikonen, E.
Mol. Biol. Cell, ***18***, *5113-5123 (2007)*

To study the principles of endocytic lipid trafficking, we introduced pyrene sphingomyelins (PyrSMs) with varying acyl chain lengths and domain partitioning properties into human fibroblasts or HeLa cells. We found that a long-chain, ordered-domain preferring PyrSM was targeted Hrs and Tsg101 dependently to late endosomal compartments and recycled to the plasma membrane in an NPC1- and cholesterol-dependent manner. A short-chain, disordered domain preferring PyrSM recycled more effectively, by using Hrs-, Tsg101- and NPC1-independent routing that was insensitive to cholesterol loading. Similar chain length-dependent recycling was observed for unlabeled sphingomyelins (SMs). The findings 1) establish acyl chain length as an important determinant in the endocytic trafficking of SMs, 2) implicate ESCRT complex proteins and NPC1 in the endocytic recycling of ordered domain lipids to the plasma membrane, and 3) introduce long-chain PyrSM as the first fluorescent lipid tracing this pathway.

3.1014 **Tight junctions contain oligomeric protein assembly critical for maintaining blood–brain barrier integrity in vivo**
McCaffrey, G. et al
J. Neurochem., ***103***, *2540-2555 (2007)*

Tight junctions (TJs) are major components of the blood–brain barrier (BBB) that physically obstruct the interendothelial space and restrict paracellular diffusion of blood-borne substances from the peripheral circulation to the CNS. TJs are dynamic structures whose intricate arrangement of oligomeric transmembrane and accessory proteins rapidly alters in response to external stressors to produce changes in BBB permeability. In this study, we investigate the constitutive trafficking of the TJ transmembrane proteins occludin and claudin-5 that are essential for forming the TJ seal between microvascular endothelial cells that inhibits paracellular diffusion. Using a novel, detergent-free **OptiPrep** density-gradient method to fractionate rat cerebral microvessels, we identify a plasma membrane lipid raft domain that contains oligomeric occludin and claudin-5. Our data suggest that oligomerization of occludin involves disulfide bond formation within transmembrane regions, and that assembly of the TJ oligomeric protein complex is facilitated by an oligomeric caveolin scaffold. This is the first time that distribution of oligomeric TJ transmembrane proteins within plasma membrane lipid rafts at the BBB has been examined *in vivo*. The findings reported in this study are critical to understand the mechanism of assembly of the TJ multiprotein complex that is essential for maintaining BBB integrity.

3.1015 **Adaptor Protein LAPF Recruits Phosphorylated p53 to Lysosomes and Triggers Lysosomal Destabilization in Apoptosis**
Li, N. et al
CancerRes., ***67(23)***, *11176-11185 (2007)*

Evidence suggests a functional association between the tumor suppressor p53 and apoptosis-involved organelle lysosome; however, the detailed mechanisms remain poorly understood. We recently reported that a lysosome-targeting protein, LAPF (lysosome-associated and apoptosis-inducing protein containing PH and FYVE domains), could initiate apoptosis of L929 cells through a lysosomal-mitochondrial pathway. In this study, we show that LAPF specifically interacted with phosphorylated p53 ($Ser^{15/18}$) both *in vitro* and *in vivo*, which could be enhanced by apoptotic stimuli, such as tumor necrosis factor α(TNF-α) and ionizing irradiation. The PH domain of LAPF and the transactivation domain of p53 mediated the interaction between both molecules. Phosphorylated p53 ($Ser^{15/18}$) could translocate to lysosomes before lysosomal membrane permeabilization (LMP) in LAPF-initiated and TNF-induced apoptosis. Silencing of LAPF expression abrogated lysosomal translocation of phosphorylated p53 ($Ser^{15/18}$), whereas silencing of p53 expression had no effect on lysosomal translocation of LAPF. Similar to that of LAPF silencing, silencing of endogenous p53 expression in L929 cells could significantly impair TNF-α–induced LMP and apoptosis. However, reexpression of wild-type p53, p53S15D (substitution of Ser^{15} to Asp that mimics a phosphorylated state), and p53R175H (a transcription-deficient mutant) in p53-knockdown L929 cells could rescue the decrease in TNF-induced apoptosis. The data suggest that phosphorylated p53 ($Ser^{15/18}$) might translocate to lysosome via forming complexes with adaptor protein LAPF and subsequently result in LMP and apoptosis, which might be in a transcription-independent manner.

3.1016 EGF-induced PIP2 hydrolysis releases and activates cofilin locally in carcinoma cells
Van Rheenen, J. et al
J. Cell Biol., ***179(6)***, *1247-1259 (2007)*

Lamellipodial protrusion and directional migration of carcinoma cells towards chemoattractants, such as epidermal growth factor (EGF), depend upon the spatial and temporal regulation of actin cytoskeleton by actin-binding proteins (ABPs). It is generally hypothesized that the activity of many ABPs are temporally and spatially regulated by PIP_2; however, this is mainly based on in vitro–binding and structural studies, and generally in vivo evidence is lacking. Here, we provide the first in vivo data that directly visualize the spatial and temporal regulation of cofilin by PIP_2 in living cells. We show that EGF induces a rapid loss of PIP_2 through PLC activity, resulting in a release and activation of a membrane-bound pool of cofilin. Upon release, we find that cofilin binds to and severs F-actin, which is coincident with actin polymerization and lamellipod formation. Moreover, our data provide evidence for how PLC is involved in the formation of protrusions in breast carcinoma cells during chemotaxis and metastasis towards EGF.

3.1017 The Epithelial Sodium Channel (ENaC) Traffics to Apical Membrane in Lipid Rafts in Mouse Cortical Collecting Duct Cells
Hill, W.G. et al
J. Biol. Chem., ***282(52)***, *37402-37411 (2007)*

We previously showed that ENaC is present in lipid rafts in A6 cells, a *Xenopus* kidney cell line. We now demonstrate that ENaC can be detected in lipid rafts in mouse cortical collecting duct ($_{MPK}CCD_{14}$) cells by detergent insolubility, buoyancy on density gradients using two distinct approaches, and colocalization with caveolin 1. Less than 30% of ENaC subunits were found in raft fractions. The channel subunits also colocalized on sucrose gradients with known vesicle targeting and fusion proteins syntaxin 1A, Vamp 2, and SNAP23. Hormonal stimulation of ENaC activity by either forskolin or aldosterone, short or long term, did not alter the lipid raft distribution of ENaC. Methyl-β-cyclodextrin added apically to $_{MPK}CCD_{14}$ cells resulted in a slow decline in amiloride-sensitive sodium transport with short circuit current reductions of 38.1 ± 9.6% after 60 min. The slow decline in ENaC activity in response to apical cyclodextrin was identical to the rate of decline seen when protein synthesis was inhibited by cycloheximide. Apical biotinylation of $_{MPK}CCD_{14}$ cells confirmed the loss of ENaC at the cell surface following cyclodextrin treatment. Acute stimulation of the recycling pool of ENaC was unaffected by apical cyclodextrin application. Expression of dominant negative caveolin isoforms (CAV1-eGFP and CAV3-DGV) which disrupt caveolae, reduced basal ENaC currents by 72.3 and 78.2%, respectively; but, as with cyclodextrin, the acute response to forskolin was unaffected. We conclude that ENaC is present in and regulated by lipid rafts. The data are consistent with a model in which rafts mediate the constitutive apical delivery of ENaC.

3.1018 Age-related subproteomic analysis of mouse liver and kidney peroxisomes
Mi, J., Garcia-Arcos, I., Alvarez, R. and Cristobal, S.
Proteome Science, ***5***, *19- (2007)*

Background

Despite major recent advances in the understanding of peroxisomal functions and how peroxisomes arise, only scant information is available regarding this organelle in cellular aging. The aim of this study was to characterize the changes in the protein expression profile of aged versus young liver and kidney peroxisome-enriched fractions from mouse and to suggest possible mechanisms underlying peroxisomal aging. Peroxisome-enriched fractions from 10 weeks, 18 months and 24 months C57bl/6J mice were analyzed by quantitative proteomics.
Results
Peroxisomal proteins were enriched by differential and density gradient centrifugation and proteins were separated by two-dimensional electrophoresis (2-DE), quantified and identified by mass spectrometry (MS). In total, sixty-five proteins were identified in both tissues. Among them, 14 proteins were differentially expressed in liver and 21 proteins in kidney. The eight proteins differentially expressed in both tissues were involved in b-oxidation, a-oxidation, isoprenoid biosynthesis, amino acid metabolism, and stress response. Quantitative proteomics, clustering methods, and prediction of transcription factors, all indicated that there is a decline in protein expression at 18 months and a recovery at 24 months.
Conclusions
These results indicate that some peroxisomal proteins show a tissue-specific functional response to aging. This response is probably dependent on their differential regeneration capacity. The differentially expressed proteins could lead several cellular effects: such as alteration of fatty acid metabolism that could alert membrane protein functions, increase of the oxidative stress and contribute to decline in bile salt synthesis. The ability to detect age-related variations in the peroxisomal proteome can help in the search for reliable and valid aging biomarkers.

3.1019 Knockdown of NHERF1 Enhances Degradation of Temperature Rescued ΔF508 CFTR from the Cell Surface of Human Airway Cells
Kwon, S-H., Pollard, H. and Giggino, W.B.
*Cell. Physiol. Biochem., **20**, 763-772 (2007)*

ΔF508 CFTR can be functionally restored in the plasma membrane by exposure of the cell to lower temperature. However, restored ΔF508 CFTR has a much shorter half-life than normal. We studied whether NHERF1, which binds to the PDZ motif of CFTR, might be a critical mediator in the turnover of ΔF508 CFTR from the cell surface. We used RNAi to reduce the expression of NHERF1 in human airway epithelial cells. Knockdown of NHERF1 reversibly reduces surface expression of WT-CFTR without altering its total expression. As expected, temperature correction increased mature C band ΔF508 CFTR (rΔF508) but unexpectedly allowed immature B band of rΔF508 to traffic to the cell surface. Both surface and total expression of rΔF508 in NHERF1 knockdown cells were reduced and degradation of surface localized rΔF508 was even faster in NHERF1 knockdown cells. Proteasomal and lysosomal inhibitor treatments led to a significant decrease in the accelerated degradation of surface rΔF508 in NHERF1 knockdown cells. These results indicate that NHERF1 plays a role in the turnover of CFTR at the cell surface, and that rΔF508 CFTR at the cell surface remains highly susceptible to degradation.

3.1020 Diversity of Raft-Like Domains in Late Endosomes
Sobo, K., Chevallier, J., Parton, R.G., Gruenberg, J. and Giscou van der Goot, F.
*PloS One, **4**, e391 (2007)*

Late endosomes, the last sorting station in the endocytic pathway before lysosomes, are pleiomorphic organelles composed of tubular elements as well as vesicular regions with a characteristic multivesicular appearance, which play a crucial role in intracellular trafficking. Here, we have investigated whether, in addition to these morphologically distinguishable regions, late endosomal membranes are additionally sub-compartmentalized into membrane microdomains.
Using sub-organellar fractionation techniques, both with and without detergents, combined with electron microscopy, we found that both the limiting membrane of the organel and the intraluminal vesicles contain raft-type membrane domains. Interestingly, these differentially localized domains vary in protein composition and physico-chemical properties.
In addition to the multivesicular organization, we find that late endosomes contain cholesterol rich microdomains both on their limiting membrane and their intraluminal vesicles that differ in composition and properties. Implications of these findings for late endosomal functions are discussed.

3.1021 Late Endosomal Cholesterol Accumulation Leads to Impaired Intra-Endosomal Trafficking
Sobo, K. et al
*PloS One, **9**, e851 (2007)*

Pathological accumulation of cholesterol in late endosomes is observed in lysosomal storage diseases such as Niemann-Pick type C. We here analyzed the effects of cholesterol accumulation in NPC cells, or as phenocopied by the drug U18666A, on late endosomes membrane organization and dynamics. Cholesterol accumulation did not lead to an increase in the raft to non-raft membrane ratio as anticipated. Strikingly, we observed a 2–3 fold increase in the size of the compartment. Most importantly, properties and dynamics of late endosomal intralumenal vesicles were altered as revealed by reduced late endosomal vacuolation induced by the mutant pore-forming toxin ASSP, reduced intoxication by the anthrax lethal toxin and inhibition of infection by the Vesicular Stomatitis Virus.
These results suggest that back fusion of intralumenal vesicles with the limiting membrane of late endosomes is dramatically perturbed upon cholesterol accumulation.

3.1022 Hsp90 Inhibition Decreases Mitochondrial Protein Turnover
Margineantu, D.H., Emerson, C.B., Diaz, D. and Hockenbery, D.M.
*PloS One, **10**, e1066 (2007)*

Background
Cells treated with hsp90 inhibitors exhibit pleiotropic changes, including an expansion of the mitochondrial compartment, accompanied by mitochondrial fragmentation and condensed mitochondrial morphology, with ultimate compromise of mitochondrial integrity and apoptosis.
Findings
We identified several mitochondrial oxidative phosphorylation complex subunits, including several encoded by mtDNA, that are upregulated by hsp90 inhibitors, without corresponding changes in mRNA abundance. Post-transcriptional accumulation of mitochondrial proteins observed with hsp90 inhibitors is also seen in cells treated with proteasome inhibitors. Detailed studies of the OSCP subunit of mitochondrial F1F0-ATPase revealed the presence of mono- and polyubiquitinated OSCP in mitochondrial fractions. We demonstrate that processed OSCP undergoes retrotranslocation to a trypsin-sensitive form associated with the outer mitochondrial membrane. Inhibition of proteasome or hsp90 function results in accumulation of both correctly targeted and retrotranslocated mitochondrial OSCP.
Conclusions
Cytosolic turnover of mitochondrial proteins demonstrates a novel connection between mitochondrial and cytosolic compartments through the ubiquitin-proteasome system. Analogous to defective protein folding in the endoplasmic reticulum, a mitochondrial unfolded protein response may play a role in the apoptotic effects of hsp90 and proteasome inhibitors.

3.1023 Kv11.1 (ERG1) K^+ Channels Localize in Cholesterol and Sphingolipid Enriched Membranes and Are Modulated by Membrane Cholesterol
Balijepalli, R.C. et al
*Channels, **14**, 263-272 (2007)*

The localization of ion channels to specific membrane microdomains can impact the functional properties of channels and their role in cellular physiology. We determined the membrane localization of human Kv11.1 (hERG1) α -subunit protein, which underlies the rapidly activating, delayed rectifier K+ current (IKr) in the heart. Immunocytochemistry and membrane fractionation using discontinuous sucrose density gradients of adult canine ventricular tissue showed that Kv11.1 channel protein localized to both the cell surface and T-tubular sarcolemma. Furthermore, density gradient membrane fractionation using detergent (Triton X-100) and non-detergent (OptiPrep) methods from canine ventricular myocytes or HEK293 cells demonstrated that Kv11.1 protein, along with MiRP1 and Kv7.1 (KCNQ1) proteins, localize in cholesterol and sphingolipid enriched membrane fractions. In HEK293 cells, Kv11.1 channels, but not long QT-associated mutant G601S-Kv11.1 channels, also localized to cholesterol and sphingolipid enriched membrane fractions. Depletion of membrane cholesterol from HEK293 cells expressing Kv11.1 channels using methyl-Mβ -cyclodextrin (Mβ CD) caused a positive shift of the voltage dependence of activation and an acceleration of deactivation kinetics of Kv11.1 current (IKv11.1). Cholesterol loading of HEK293 cells reduced the steep voltage dependence of IKv11.1 activation and accelerated the inactivation kinetics of IKv11.1. Incubation of neonatal mouse myocytes in Mβ CD also accelerated the deactivation kinetics of

IKr. We conclude that Kv11.1 protein localizes in cholesterol and sphingolipid enriched membranes and that membrane cholesterol can modulate IKv11.1 and IKr.

3.1024 Association of Botulinum Neurotoxin Serotypes A and B with Synaptic Vesicle Protein Complexes
Baldwin, M.R. and Barbieri, J.T.
Biochemistry, ***46(11)***, *3200-3210 (2007)*

Botulinum neurotoxins (BoNTs) elicit flaccid paralysis through cleavage of SNARE proteins within peripheral neurons. There are seven serotypes of the BoNTs, termed A-G, which differ in the SNARE protein and/or site that is cleaved. BoNTs are single-chain toxins that comprise an N-terminal zinc metalloprotease domain that is disulfide linked to the C-terminal translocation/receptor binding domain. SV2 and synaptotagmin have been identified as receptors for BoNT serotypes A and B, respectively. Using affinity chromatography, BoNTs A and B were observed to bind synaptic vesicle protein complexes in synaptosome lysates. Tandem LC-MS/MS identified SV2, synaptotagmin I, synaptophysin, vesicle-associated membrane protein 2 (VAMP2), and the vacuolar proton pump as components of the BoNT-receptor complex. Density gradient analysis showed that BoNT serotypes A and B exhibited unique interactions with the synaptic vesicle protein complexes. The association of BoNT serotypes A and B with synaptic vesicle protein complexes implicates a physiological role for protein complexes in synaptic vesicle biology and provides insight into the interactions of BoNT and neuronal receptors.

3.1025 Vascular Endothelial Growth Factor Receptor-3 Activity Is Modulated by Its Association with Caveolin-1 on Endothelial Membrane
Galvagni, F. et al
Biochemistry, ***46(13)***, *3998-4005 (2007)*

Vascular endothelial growth factor receptor-3 (VEGFR-3) is constitutively expressed in lymphatic vessels and transiently in endothelial cells of blood vessels during angiogenesis. Here we report that VEGFR-3 localizes in the caveolae membrane of endothelial cells and co-immunoprecipitates with caveolin-1. Caveolin-1 silencing or its depletion from the cell membrane by cholesterol increases VEGFR-3 autophosphorylation, suggesting that caveolin acts as a negative regulator of VEGFR-3 activity. Receptor activation induces caveolin-1 phosphorylation on tyrosine residues including tyrosine 14. Cell treatment with Src or Abl inhibitors PP2 or STI571, prior to receptor stimulation, affects caveolin-1 phosphorylation without affecting receptor autophosphorylation, suggesting that both Src and Abl are involved in VEGFR-3-dependent caveolin-1 phosphorylation. Caveolin-1 phosphorylation in Src/Fyn/Yes knockout cells demonstrated that Abl phosphorylates caveolin-1 independently from Src family members. These results suggest a functional interaction between VEGFR-3 and caveolin-1 to modulate endothelial cell activation during angiogenesis.

3.1026 Role of the Hydrophobic Segment of Diacylglycerol Kinase ε
Dicu, A.O., Topham, M.K., Ottaay, L. and Epand, R.M.
Biochemistry, ***46(20)***, *6109-6117 (2007)*

Diacylglycerol kinase ε(DGKε) is unique among mammalian DGK isoforms in having a segment of hydrophobic amino acids. We have evaluated the contributions of this segment to the membrane interactions and functions of this protein. To test the role of the hydrophobic segment, we have compared the properties of DGKε with those of a truncated form of the protein (DGKΔε) lacking the 40 N-terminal amino acids, which includes the hydrophobic segment. The proteins were expressed in COS-7 cells from a gene for human DGKε or from a gene for a truncated form (DGKΔε), both of which had a FLAG tag at the amino terminus. Full-length FLAG-DGKε and truncated FLAG-DGKΔε were both more specific for 1-stearoyl-2-arachidonoyl-*sn*-glycerol than for 1,2-dioleoyl-*sn*-glycerol. 1-Stearoyl-2-linoleoyl-*sn*-glycerol exhibited intermediate specificity for both forms of the enzyme. The results show that the truncated form of the enzyme maintains substrate specificity for lipids with an arachidonoyl moiety present at the *sn*-2 position. The truncation increases the catalytic rate constant for all three substrates and may suggest a role in the negative regulation of this enzyme. A full-length DGKε with a C-terminal His tag exhibited substrate specificity similar to that of the other two forms of the enzyme, indicating that the nature and position of the epitope tag did not strongly affect this property. Using an ultracentrifugation floatation assay, we showed that at neutral pH DGKΔε is extracted with 1.5 M KCl while DGKε remains essentially fully membrane bound. The full-length protein had a weak tendency to oligomerize in the presence of weak detergents. DGKε was monomeric on SDS-PAGE but exhibited partial dimerization with low concentrations of perfluorooctanoic acid. The major conclusions of this work are that the hydrophobic

domain of DGKε does not contribute to substrate specificity but plays a role in permanently sequestering the enzyme to a membrane.

3.1027 Lipid Interaction Converts Prion Protein to a PrP^{Sc}-like Proteinase K-Resistant Conformation under Physiological Conditions
Wang, F. et al
Biochemistry, ***46(23)***, *7045-7053 (2007)*

The conversion of prion protein (PrP) to the pathogenic PrP^{Sc} conformation is central to prion disease. Previous studies revealed that PrP interacts with lipids and the interaction induces PrP conformational changes, yet it remains unclear whether in the absence of any denaturing treatment, PrP-lipid interaction is sufficient to convert PrP to the classic proteinase K-resistant conformation. Using recombinant mouse PrP, we analyzed PrP-lipid interaction under physiological conditions and followed lipid-induced PrP conformational change with proteinase K (PK) digestion. We found that the PrP-lipid interaction was initiated by electrostatic contact and followed by hydrophobic interaction. The PrP-lipid interaction converted full-length α-helix-rich recombinant PrP to different forms. A significant portion of PrP gained a conformation reminiscent of PrP^{Sc}, with a PrP^{Sc}-like PK-resistant core and increased β-sheet content. The efficiency for lipid-induced PrP conversion depended on lipid headgroup structure and/or the arrangement of lipids on the surface of vesicles. When lipid vesicles were disrupted by Triton X-100, PrP aggregation was necessary to maintain the lipid-induced PrP^{Sc}-like conformation. However, the PK resistance of lipid-induced PrP^{Sc}-like conformation does not depend on amyloid fiber formation. Our results clearly revealed that the lipid interaction can overcome the energy barrier and convert full-length α-helix-rich PrP to a PrP^{Sc}-like conformation under physiological conditions, supporting the relevance of lipid-induced PrP conformational change to in vivo PrP conversion.

3.1028 Human ABCB6 Localizes to Both the Outer Mitochondrial Membrane and the Plasma Membrane
Paterson, J.K. et al
Biochemistry, ***46(33)***, *9443-9452 (2007)*

Expression of the ATP-binding cassette transporter ABCB6 has been associated with multiple cellular functions, including resistance to several cytotoxic agents, iron homeostasis, and porphyrin transport. To further elucidate its physiological function and/or role in drug resistance, we determined the subcellular location of ABCB6. Using three novel ABCB6-specific antibodies, Western blot analysis of cells expressing cDNA-derived or endogenous ABCB6 revealed two distinct molecular weight forms. Confocal microscopy indicates that the protein localizes to both mitochondria and the plasma membrane. Differential centrifugation revealed that the lower molecular weight form predominantly resides in the mitochondria, while the larger protein form is more abundant in the plasma membrane. Preliminary studies indicate that ABCB6 is functionally relevant in the plasma membrane, where its expression prevents the accumulation of specific porphyrins in the cell. Digitonin solubilization of mitochondria demonstrated that ABCB6 is present in the outer mitochondrial membrane, while back-titration assays with the ABCB6-specific antibodies reveal that the nucleotide binding domain of ABCB6 is cytoplasmic. These studies are the first to demonstrate that ABCB6 exists in two molecular weight forms, is localized to both the outer mitochondrial membrane and the plasma membrane, and plays a functional role in the plasma membrane.

3.1029 Subcellular Proteome Analysis of Camptothecin Analogue NSC606985-Treated Acute Myeloid Leukemic Cells
Yu, Y. et al
J. Proteome Res., ***6(9)***, *3808-3818 (2007)*

We reported previously that NSC606985, a camptothecin analogue, induces apoptosis of acute myeloid leukemia (AML) cells through proteolytic activation of protein kinase Cδ. Here, we analyzed protein expression profiles of fractionated nuclei, mitochondria, raw endoplasmic reticula, and cytosols of NSC606985-induced apoptotic AML cell line NB4 cells by two-dimensional electrophoresis combined with MALDI-TOF/TOF tandem mass spectrometry. In total, 90 unique deregulated proteins, including 16 compartment-compartment translocated ones, were identified. They contributed to multiple functional activities such as DNA damage repairing, chromosome assembly, mRNA processing, biosynthesis, modification, and degradation of proteins. More interestingly, several increased oxidative stress-related proteins mainly presented in mitochondria, while upregulated glycolysis proteins mainly occurred in the nuclei. With their functional analyses, the possible roles of these deregulated proteins in NSC606985-

induced apoptosis were discussed. Collectively, these discoveries would shed new insights for systematically understanding the mechanisms of the camptothecin-induced apoptosis.

3.1030 Proteomic Complex Detection Using Sedimentation
Hartman, N.T., Sicilia, F., Lilley, K.S. and Dupree, P.
Anal. Chem., ***79(5)***, *2078-2083 (2007)*

Protein-protein interactions are important in many cellular processes, but there are still relatively few methods to screen for novel protein complexes. Here we present a quantitative proteomics technique called ProCoDeS (Proteomic Complex Detection using Sedimentation) for profiling the sedimentation of a large number of proteins through a rate zonal centrifugation gradient. Proteins in a putative complex can be identified since they sediment faster than predicted from their monomer molecular weight. Using solubilized mitochondrial membrane proteins from *Arabidopsis thaliana*, the relative protein abundance in fractions of a rate zonal gradient was measured with the isotopic labeling reagent ICAT and electrospray mass spectrometry. Subunits of the same protein complex had very similar gradient distribution profiles, demonstrating the reproducibility of the quantitation method. The approximate size of the unknown complex can be inferred from its sedimentation rate relative to known protein complexes. ProCoDeS will be of use in screening extracts of tissues, cells, or organelle fractions to identify specific proteins in stable complexes that can be characterized by subsequent targeted techniques such as affinity tagging.

3.1031 PINK1 Protects against Oxidative Stress by Phosphorylating Mitochondrial Chaperone TRAP1
Pridgeon, J.W., Olzmann, J.A., Chin, L-S. and Li, L.
PloS Biology, ***5(7)***, *1494-1503 (2007)*

Mutations in the *PTEN induced putative kinase 1 (PINK1)* gene cause an autosomal recessive form of Parkinson disease (PD). So far, no substrates of PINK1 have been reported, and the mechanism by which PINK1 mutations lead to neurodegeneration is unknown. Here we report the identification of TNF receptor-associated protein 1 (TRAP1), a mitochondrial molecular chaperone also known as heat shock protein 75 (Hsp75), as a cellular substrate for PINK1 kinase. PINK1 binds and colocalizes with TRAP1 in the mitochondria and phosphorylates TRAP1 both in vitro and in vivo. We show that PINK1 protects against oxidative-stress-induced cell death by suppressing cytochrome c release from mitochondria, and this protective action of PINK1 depends on its kinase activity to phosphorylate TRAP1. Moreover, we find that the ability of PINK1 to promote TRAP1 phosphorylation and cell survival is impaired by PD-linked PINK1 G309D, L347P, and W437X mutations. Our findings suggest a novel pathway by which PINK1 phosphorylates downstream effector TRAP1 to prevent oxidative-stress-induced apoptosis and implicate the dysregulation of this mitochondrial pathway in PD pathogenesis.

3.1032 Distinct role of clathrin-mediated endocytosis in the functional uptake of cholera toxin
Vanden Broeck, D., Lagrou, A.R. and De Wolf, M.J.S.
Acta Biochimica Polonica, ***54(4)***, *757-767 (2007)*

The involvement of the clathrin-mediated endocytic internalization route in the uptake of cholera toxin (CT) was investigated using different cell lines, including the human intestinal Caco-2 and T84 cell lines, green monkey Vero cells, SH-SY5Y neuroblastoma cells and Madin-Darby canine kidney cells. Suppression of the clathrin-mediated endocytic pathway by classical biochemical procedures, like intracellular acidification and potassium depletion, inhibited cholera toxin uptake by up to about 50% as well as its ability to raise intracellular levels of cAMP. Also prior exposure of these cell types to the cationic amphiphilic drug chlorpromazine reduced the functional uptake of cholera toxin, even to a greater extent. These effects were dose- and cell type-dependent, suggesting an involvement of clathrin-mediated endocytosis in the functional uptake of cholera toxin. For a more straightforward approach to study the role of the clathrin-mediated uptake in the internalization of cholera toxin, a Caco-2^{eps-} cell line was exploited. These Caco-2^{eps-} cells constitutively suppress the expression of epsin, an essential accessory protein of clathrin-mediated endocytosis, thereby selectively blocking this internalization route. CT uptake was found to be reduced by over 60% in Caco-2^{eps-} paralleled by a diminished ability of CT to raise the level of cAMP. The data presented suggest that the clathrin-mediated uptake route fulfils an important role in the functional internalization of cholera toxin in several cell types.

3.1033 Quantitative proteomic comparison of mouse peroxisomes from liver and kidney
Mi, J., Kirchner, E. and Cristobal, S.
Proteomics, ***7(11)***, *1916-1928 (2007)*

The peroxisome plays a central role in the catabolic and anabolic pathways that contribute to the lipid homeostasis. Besides this main function, this organelle has gained functional diversity. Although several approaches have been used for peroxisomal proteome analysis, a quantitative protein expression analysis of peroxisomes from different tissues has not been elucidated yet. Here, we applied a 2-DE-based method on mouse liver and kidney peroxisomal enriched fractions to study the tissue-dependent protein expression. Ninety-one spots were identified from the 2-DE maps from pH 3.0–10.0 and 51 spots from the basic range corresponding to 31 peroxisomal proteins, 10 putative peroxisomal, 6 cytosolic, 17 mitochondrial and 1 protein from endoplasmic reticulum. Based on the identification and on the equivalent quality of both tissue preparations, the differences emerging from the comparison could be quantified. In liver, proteins involved in pathways such as α- and β-oxidation, isoprenoid biosynthesis, amino acid metabolism and purine and pirimidine metabolism were more abundant whereas in kidney, proteins from the straight-chain fatty acid β-oxidation were highly expressed. These results indicate that tissue-specific functional classes of peroxisomal proteins could be relevant to study peroxisomal cellular responses or pathologies. Finally, a web-based peroxisomal proteomic database was built.

3.1034 Analysis of the linkage of MYRIP and MYO7A to melanosomes by RAB27A in retinal pigment epithelial cells

Klomp, A.E., teofilo, K., Legacki, E. and Williams, D.S.
*Cell Motil. Cytoskeleton, **64(6)**, 474-487 (2007)*

The apical region of the retinal pigment epithelium (RPE) typically contains melanosomes. Their apical distribution is dependent on RAB27A and the unconventional myosin, MYO7A. Evidence from studies using in vitro binding assays, melanocyte transfection, and immunolocalization have indicated that the exophilin, MYRIP, links RAB27A on melanosomes to MYO7A, analogous to the manner that melanophilin links RAB27A on melanocyte melanosomes to MYO5A. To test the functionality of this hypothesis in RPE cells, we have examined the relationship among MYRIP, RAB27A and MYO7A with studies of RPE cells in primary culture (including live-cell imaging), analyses of mutant mouse retinas, and RPE cell fractionation experiments. Our results indicate that the retinal distribution of MYRIP is limited to the RPE, mainly the apical region. In RPE cells, RAB27A, MYRIP, and MYO7A were all associated with melanosomes, undergoing both slow and rapid movements. Analyses of mutant mice provide genetic evidence that MYRIP is linked to melanosomes via RAB27A, but show that recruitment of MYRIP to apical RPE is independent of melanosomes and RAB27A. RAB27A and MYRIP also associated with motile small vesicles of unknown origin. The present results provide evidence from live RPE cells that the RAB27A-MYRIP-MYO7A complex functions in melanosome motility. They also demonstrate that RAB27A provides an essential link to the melanosome.

3.1035 Reduced raft-association of NF155 in active MS-lesions is accompanied by the disruption of the paranodal junction

Maier, O., Baron, W. and Hoekstra, D.
*GLIA, **55(8)**, 885-895 (2007)*

Neurofascin155 (NF155) is required for the establishment of the paranodal axo-glial junction, the predominant interaction site between myelin and axon. It has been shown that the distribution of NF155 is altered in demyelinating diseases such as multiple sclerosis (MS). However, little is known about the biochemical mechanisms underlying these changes. We therefore compared NF155 in postmortem tissue of active and chronic inactive MS lesions with white matter from healthy controls. Although NF155 showed a very similar expression in all control white matter samples, a strong individual variation was observed in MS-lesions with NF155-levels reduced in most samples. At the same time an NF155-fragment was increased in MS-lesions, suggesting that NF155 is subject to protein degradation in lesion sites. Interestingly, the association of NF155 to membrane microdomains (rafts) was reduced in all lesions, irrespective of the amount of NF155, indicating that membrane association of NF155 was generally affected. Therefore, myelin fractionation experiments were performed to analyze the fate of paranodal proteins during demyelination. Although NF155 was enriched in heavy myelin from both control white matter and active MS-lesions, association of Caspr1/paranodin with heavy myelin was abolished in MS-lesions, demonstrating that paranodal junctions are disrupted. In conclusion, the data support the hypothesis that efficient raft-association of NF155 is essential for the assembly of the paranodal junction and demonstrate that reduced association of NF155 to lipid rafts is accompanied by the disassembly of the paranodal junction and thus contributes to the demyelination process in MS.

3.1036 Mitochondrial association of myocilin, product of a glaucoma gene, in human trabecular meshwork cells

Sakai, H., Shen, X., Koga, T., Park, B-C., Noskina, Y., Tibudan, M. and Yue, B.Y.J.T.
J. Cell. Physiol., ***213(3)***, *775-784 (2007)*

The trabecular meshwork (TM), an ocular tissue next to the cornea, is a major site for regulation of the aqueous humor outflow. Malfunctioning of this tissue is believed to be responsible for development of glaucoma, a major blinding disease. Myocilin is a gene directly linked to the most common form of glaucoma. Its protein product has been localized to both intra- and extra-cellular sites in TM cells. This study was to investigate the association of myocilin with mitochondria in TM cells. In vitro mitochondrial import assays showed that myocilin was imported to the TM mitochondria, targeting to mitochondrial membranes and/or the intermembrane space. The targeting was mediated mostly via the amino-terminal region of myocilin. When myocilin expression was induced either by treatment with dexamethasone or transfection with a myocilin construct, the mitochondrial membrane potential in TM cells, as assessed by JC-1 staining, was lowered. Subcellular fractionation and Western blot analyses confirmed that a portion of myocilin sedimented with the mitochondrial fractions. Upon anti-Fas treatment to provoke apoptosis, an increase of myocilin distribution in cytosolic fraction was observed, suggesting that myocilin was partially released from mitochondrial compartments. These results confirmed the association of myocilin with TM cell mitochondria and indicated that myocilin may have a proapoptotic role in TM cells.

3.1037 Assembly and budding of a hepatitis B virus is mediated by a novel type of intracellular vesicles

Mhamdi, M., Funk, A., Hohenberg, H., Will, H. and Sirma, H.
Hepatology, ***46(1)***, *95-106 (2007)*

Formation of enveloped viruses involves assembly and budding at cellular membranes. In this study, we elucidated the morphogenesis of hepadnaviruses on the ultrastructural and biochemical level using duck hepatitis B virus (DHBV) as a model system. Formation of virus progeny initiates at the endoplasmic reticulum (ER) and is conserved both in vitro and in vivo. The morphogenesis proceeds via membrane-surrounded vesicles containing both virions and subviral particles, indicating a common morphogenetic pathway. The virus particle–containing vesicles (VCVs) are generated and maintained by reorganization of endomembranes accompanied by a striking disorganization of the rough ER (rER). VCVs are novel organelles with unique identity and properties of ER, intermediate compartment, endosomes, and multivesicular bodies. VCVs are dynamic structures whose size and shape are regulated by both membrane fusion and fission. *Conclusion:* Our data indicate a strong reorganization of endomembranes during DHBV infection, resulting in the biogenesis of novel organelles serving as multifunctional platforms for assembly and budding of virus progeny.

3.1038 Nondetergent Isolation of Rafts

Shah, M.B. and Sehgal, P.B.
Methods Mol. Biol., ***398***, *21-28 (2007)*

Raft and caveolar microdomains have been proposed to participate in numerous cellular functions including signal transduction, cholesterol trafficking, and vesicular sorting. Traditional methods of isolation of rafts from cultured cells and tissue samples have exploited the biochemical properties of these microdomains, i.e., their relative resistance to solubilization by nonionic detergents (at 4°C) and their light buoyant density attributable to their high content of cholesterol and sphingolipids. Thus, a common way to isolate raft microdomains has been their separation on a density gradient in the presence of 0.5–1% Triton X-100 (Bochringer Mannheim Roche Applied Sciences Indianapolis, IN or Sigma-Aldrich, St. Louis, MO). This and other detergent-based methods have been discussed. However, the use of detergents may not be favorable because of artifacts that may arise with their use. (The possibility of rafts solely as detergent-induced artifacts appears to have been diffused by a number of biochemical and biophysical studies that strongly demonstrate the presence of a liquid-ordered phase within biological membranes.) In this chapter, three methods are reviewed to isolate rafts from cultured cells without the use of detergents. Two of these, the sodium carbonate and OptiPrep™ (Sigma-Aldrich St. Louis, MO) methods, are based on gradient separation and can be used to isolate rafts in general, whereas the third is a magnetic-bead immunoisolation approach and might be used to isolate subpopulations of rafts enriched for different markers such as caveolin-1, flotillin (reggie proteins), or other suitable markers. Together these methods allow for a detergent-free isolation of rafts for biochemical, proteomic, and microscopic studies.

3.1039 Proteomics-Based Method for Risk Assessment of Peroxisome Proliferating Pollutants in the Marine Environment
Cristobal, S.
Methods Mol. Biol., ***410****, 123-135 (2007)*

Pollution in aquatic environment is of increasing concern for its impact on both human and natural populations. Applying proteomics to monitor marine pollution is a new approach to evaluate the effects of environmental pollutants on the biota. Aquatic organisms living in coastal and estuarine areas are particularly prone to exposures to a variety of pollutants, some of which can act as peroxisome proliferators. However, peroxisomal responses in particular and biomarker responses in general can be influenced by several biotic and abiotic factors. Utilizing proteomics-based techniques that permit the evaluation of hundreds to thousands of proteins in a single experiment can circumvent those drawbacks. Applying this method, the peroxisomal proteome from digestive glands of mussels *Mytilus sp*. can be analyzed by two-dimensional electrophoresis (2-DE) and the 2-DE maps from control samples and samples obtained in a polluted area can be compared. The up- and down-regulated proteins compose the protein expression signature (PES) associated with exposure to peroxisome proliferating pollutants. This method generates highly reproducible patterns that can be applied to laboratory or field experiments.

3.1040 Regulation of Notch Signaling by Dynamic Changes in the Precision of S3 Cleavage of Notch-1
Tagami, S. et al
Mol. Cell. Biol., ***28(1)****, 165-176 (2008)*

Intramembrane proteolysis by presenilin-dependent γ-secretase produces the Notch intracellular cytoplasmic domain (NCID) and Alzheimer disease-associated amyloid-β. Here, we show that upon Notch signaling the intracellular domain of Notch-1 is cleaved into two distinct types of NICD species due to diversity in the site of S3 cleavage. Consistent with the N-end rule, the S3-V cleavage produces stable NICD with Val at the N terminus, whereas the S3-S/S3-L cleavage generates unstable NICD with Ser/Leu at the N terminus. Moreover, intracellular Notch signal transmission with unstable NICDs is much weaker than that with stable NICD. Importantly, the extent of endocytosis in target cells affects the relative production ratio of the two types of NICD, which changes in parallel with Notch signaling. Surprisingly, substantial amounts of unstable NICD species are generated from the Val→Gly and the Lys→Arg mutants, which have been reported to decrease S3 cleavage efficiency in cultured cells. Thus, we suggest that the existence of two distinct types of NICD points to a novel aspect of the intracellular signaling and that changes in the precision of S3 cleavage play an important role in the process of conversion from extracellular to intracellular Notch signaling.

3.1041 Protein-sphingolipid interactions within cellular membranes
Haberkant, P. et al
J. Lipid Res., ***49****, 251-262 (2008)*

Each intracellular organelle critically depends on maintaining its specific lipid composition that in turn contributes to the biophysical properties of the membrane. With our knowledge increasing about the organization of membranes with defined microdomains of different lipid compositions, questions arise regarding the molecular mechanisms that underlie the targeting to/segregation from microdomains of a given protein. In addition to specific lipid-transmembrane segment interactions as a basis for partitioning, the presence in a given microdomain may alter the conformation of proteins and, thus, the activity and availability for regulatory modifications. However, for most proteins, the specific lipid environment of transmembrane segments as well as its relevance to protein function and overall membrane organization are largely unknown. To help fill this gap, we have synthesized a novel photoactive sphingolipid precursor that, together with a precursor for phosphoglycerolipids and with photo-cholesterol, was investigated in vivo with regard to specific protein transmembrane span-lipid interactions. As a proof of principle, we show specific labeling of the ceramide transporter with the sphingolipid probe and describe specific in vivo interactions of lipids with caveolin-1, phosphatidylinositol transfer protein β, and the mature form of nicastrin. This novel photolabile sphingolipid probe allows the detection of protein-sphingolipid interactions within the membrane bilayer of living cells.

3.1042 Cytoplasmic Domain of Influenza B Virus BM2 Protein Plays Critical Roles in Production of Infectious Virus
Imai, M., Kawasaki, K. and Odagiri, T.
J. Virol., ***82(2)****, 728-739 (2008)*

Influenza B virus BM2 is a type III integral membrane protein that displays H^+ ion channel activity. Analysis of BM2 knockout mutants has suggested that this protein is a necessary component for the capture of M1-viral ribonucleoprotein (vRNP) complex at the plasma membrane and for incorporation of vRNP complex into the virion during the assembly process. BM2 comprises 109 amino acid residues and possesses a longer cytoplasmic domain than the other 3 integral membrane proteins (hemagglutinin, neuraminidase, and NB). To explore whether the cytoplasmic domain of BM2 is important for infectious virus production, a series of BM2 deletion mutants lacking three to nine amino acid residues at the carboxyl terminus, BM2Δ107-109, BM2Δ104-109, and BM2Δ101-109, was generated by reverse genetics. Intracellular transport and incorporation into virions were indistinguishable between truncated BM2 proteins and wild-type BM2. The BM2Δ107-109 mutant produced levels of infectious virus similar to those of wild-type virus and displayed a spherical shape. However, the BM2Δ104-109 and BM2Δ101-109 mutants produced viruses containing dramatically reduced vRNP complex, as with BM2 knockout mutants, and formed enlarged, irregularly shaped virions. Moreover, gradient separation of membranes indicated that membrane association of M1 from mutants was greatly affected by carboxyl-terminal truncations of BM2. Studies of alanine substitution mutants further suggested that amino acid sequences in the 98-109 region are variable while those in the 86-97 region are a prerequisite for innate BM2 function. These results indicate that the cytoplasmic domain of the BM2 protein is required for firm association of the M1 protein with lipid membranes, vRNP complex incorporation into virions, and virion morphology.

3.1043 Mint3/X11$^{\gamma}$ Is an ADP-Ribosylation Factor-dependent Adaptor that Regulates the Traffic of the Alzheimer's Precursor Protein from the Trans-Golgi Network
Shrivastava-Ranjan, P. et al
*Mol. Biol. Cell, **19**, 51-64 (2008)*

β-Amyloid peptides (Aβ) are the major component of plaques in brains of Alzheimer's patients, and are they derived from the proteolytic processing of the β-amyloid precursor protein (APP). The movement of APP between organelles is highly regulated, and it is tightly connected to its processing by secretases. We proposed previously that transport of APP within the cell is mediated in part through its sorting into Mint/X11-containing carriers. To test our hypothesis, we purified APP-containing vesicles from human neuroblastoma SH-SY5Y cells, and we showed that Mint2/3 are specifically enriched and that Mint3 and APP are present in the same vesicles. Increasing cellular APP levels increased the amounts of both APP and Mint3 in purified vesicles. Additional evidence supporting an obligate role for Mint3 in traffic of APP from the *trans*-Golgi network to the plasma membrane include the observations that depletion of Mint3 by small interference RNA (siRNA) or mutation of the Mint binding domain of APP changes the export route of APP from the basolateral to the endosomal/lysosomal sorting route. Finally, we show that increased expression of Mint3 decreased and siRNA-mediated knockdowns increased the secretion of the neurotoxic β-amyloid peptide, $A\beta_{1\text{-}40}$. Together, our data implicate Mint3 activity as a critical determinant of post-Golgi APP traffic.

3.1044 Localization of phosphorylated αB-crystallin to heart mitochondria during ischemia-reperfusion
Jin, J-K. et al
*Am. J. Physiol. Heart Circ. Physiol., **294**, H337-H344 (2008)*

The cytosolic small heat shock protein αB-crystallin (αBC) is a molecular chaperone expressed in large quantities in the heart, where it protects from stresses such as ischemia-reperfusion (I/R). Upon I/R, p38 MAP kinase activation leads to phosphorylation of αBC on Ser^{59} (P-αBC-S59), which increases its protective ability. αBC confers protection, in part, by interacting with and affecting the functions of key components in stressed cells. We investigated the hypothesis that protection from I/R damage in the heart by P-αBC-S59 can be mediated by localization to mitochondria. We found that P-αBC-S59 localized to mitochondria isolated from untreated mouse hearts and that this localization increased more than threefold when the hearts were subjected to ex vivo I/R. Mitochondrial P-αBC-S59 decreased when hearts were treated with the p38 inhibitor SB-202190. Moreover, SB-202190-treated hearts exhibited more tissue damage and less functional recovery upon reperfusion than controls. I/R activates mitochondrial permeability transition (MPT) pore opening, which increases cell damage. We found that mitochondria incubated with a recombinant mutant form of αBC that mimics P-αBC-S59 exhibited decreased calcium-induced MPT pore opening. These results indicate that mitochondria may be among the key components in stressed cells with which P-αBC-S59 interacts and that this localization may protect the myocardium, in part, by modulating MPT pore opening and, thus, reducing I/R injury.

3.1045 Lpx1p is a peroxisomal lipase required for normal peroxisome morphology
Thoms, S., Debelyy, M.O., Nau, K., Meyer, H.E. and Erdmann, R.
*FEBS J., **275**, 504-514 (2008)*

Lpx1p (systematic name: Yor084wp) is a peroxisomal protein from *Saccharomyces cerevisiae* with a peroxisomal targeting signal type 1 (PTS1) and a lipase motif. Using mass spectrometry, we have identified Lpx1p as present in peroxisomes, and show that Lpx1p import is dependent on the PTS1 receptor Pex5p. We provide evidence that Lpx1p is piggyback-transported into peroxisomes. We have expressed the Lpx1p protein in *Escherichia coli*, and show that the enzyme exerts acyl hydrolase and phospholipase A activity *in vitro*. However, the protein is not required for wild-type-like steady-state function of peroxisomes, which might be indicative of a metabolic rather than a biogenetic role. Interestingly, peroxisomes in deletion mutants of *LPX1* have an aberrant morphology characterized by intraperoxisomal vesicles or invaginations.

3.1046 Use of polarized PC12 cells to monitor protein localization in the early biosynthetic pathway
Sannerud, R., Michaël, M., Berger hansen, B. And Saraste, J.
*Methods in Mol. Biol., **457**, 253-265 (2008)*

A prerequisite for understanding the cellular functions of an unknown protein is the establishment of its subcellular localization. As increasing numbers of novel proteins of the biosynthetic pathway are currently being identified, accessible new methods are required to facilitate their localization. Differentiating rat pheochromocytoma (PC12) cells reorganize their biosynthetic membrane compartments as they develop neurite-like processes. The authors recently showed that polarization of these cells involves the expansion of the intermediate compartment (IC) between the rough endoplasmic reticulum (RER) and the Golgi apparatus. Tubules emerging from the vacuolar parts of the IC move to the developing neurites accumulating in their growth cones, whereas the vacuoles, like RER and Golgi, remain in the cell body. Thus, polarized PC12 cells enhance the resolution for immunofluorescence microscopic mapping of protein localization in the early biosynthetic pathway. The authors also describe here a rapid cell fractionation protocol employing velocity sedimentation in iodixanol gradients that allows one-step separation of the pre-Golgi vacuoles, tubules, and RER.

3.1047 Multidrug Transporters CaCdr1p and CaMdr1p of Candida albicans Display Different Lipid Specificities: both Ergosterol and Sphingolipids Are Essential for Targeting of CaCdr1p to Membrane Rafts
Pasrija, R., Panwar, S.L. and Prasad R.
*Antimicrob.Agents Chemother., **52(2)**, 694-704 (2008)*

In this study, we compared the effects of altered membrane lipid composition on the localization of two membrane drug transporters from different superfamilies of the pathogenic yeast *Candida albicans*. We demonstrated that in comparison to the major facilitator superfamily multidrug transporter CaMdr1p, ATP-binding cassette transporter CaCdr1p of *C. albicans* is preferentially localized within detergent-resistant membrane (DRM) microdomains called 'rafts.' Both CaCdr1p and CaMdr1p were overexpressed as green fluorescent protein (GFP)-tagged proteins in a heterologous host *Saccharomyces cerevisiae*, wherein either sphingolipid (Δ*sur4* or Δ*fen1* or Δ*ipt1*) or ergosterol (Δ*erg24* or Δ*erg6* or Δ*erg4*) biosynthesis was compromised. CaCdr1p-GFP, when expressed in the above mutant backgrounds, was not correctly targeted to plasma membranes (PM), which also resulted in severely impaired drug resistance. In contrast, CaMdr1p-GFP displayed no sorting defect in the mutant background and remained properly surface localized and displayed no change in drug resistance. Our data clearly show that CaCdr1p is selectively recruited, over CaMdr1p, to the DRM microdomains of the yeast PM and that any imbalance in the raft lipid constituents results in missorting of CaCdr1p.

3.1048 Compartmentalization of endocannabinoids into lipid rafts in a dorsal root ganglion cell line
Rimmermann, N. et al
*Br. J. Pharmacol., **153**, 380-389 (2008)*

Background and purpose:
N-arachidonoyl ethanolamine (AEA) and 2-arachidonoyl glycerol (2-AG) are endogenous cannabinoids binding to the cannabinoid receptors CB_1 and CB_2 to modulate neuronal excitability and synaptic transmission in primary afferent neurons. To investigate the compartmentalization of the machinery for

AEA and 2-AG signalling, we studied their partitioning into lipid raft fractions isolated from a dorsal root ganglion X neuroblastoma cell line (F-11).
Experimental approach:
F-11 cells were homogenized and fractionated using a detergent-free OptiPrep density gradient. All lipids were partially purified from methanolic extracts of the fractions on solid phase cartridges and quantified using liquid chromatography tandem mass spectrometry (LC/MS/MS). Protein distribution was determined by Western blotting.
Key results:
Under basal conditions, the endogenous cannabinoid AEA was present in both lipid raft and specific non-lipid raft fractions as was one of its biosynthetic enzymes, NAPE-PLD. The 2-AG precursor 1-stearoyl-2-arachidonoyl-*sn*-glycerol (DAG), diacylglycerol lipase ∝(DAGL∝), which cleaves DAG to form 2-AG, and 2-AG were all co-localized with lipid raft markers. CB_1 receptors, previously reported to partition into lipid raft fractions, were not detected in F-11 membranes, but CB_2 receptors were detected at high levels and partitioned into non-lipid raft fractions.
Conclusions and implications:
The biochemical machinery for the production of 2-AG via the putative diacylglycerol pathway is localized within lipid rafts, suggesting that 2-AG synthesis via DAG occurs within these microdomains. The observed co-localization of AEA, 2-AG, and their synthetic enzymes with the reported localization of CB_1 raises the possibility of intrinsic-autocrine signalling within lipid raft domains and/or retrograde-paracrine signalling.

3.1049 The α1a-Adrenergic Receptor Occupies Membrane Rafts with Its G Protein Effectors but Internalizes via Clathrin-coated Pits
Morris, D.P., Lei, B., Wu, Y-X., Michelotti, G.-A. and Schwinn, D.A.
J. Biol. Chem., ***283(5)***, *2973-2985 (2008)*

The α_{1a}-adrenergic receptor (α_{1a}AR) occupies intracellular and plasma membranes in both native and heterologous expression systems. Based on multiple independent lines of evidence, we demonstrate the α_{1a}AR at the cell surface occupies membrane rafts but exits from rafts following stimulation. In non-detergent raft preparations, basal α_{1a}AR is present in low density membrane rafts and colocalizes with its G protein effectors on density gradients. Raft disruption by cholesterol depletion with methyl-β-cyclodextrin eliminates these light rafts. To confirm the presence of the α_{1a}AR in plasma membrane rafts, fluorescence resonance energy transfer measurements were used to demonstrate colocalization of surface receptor and the raft marker, cholera toxin B. This colocalization was largely lost following α_{1a}AR stimulation with phenylephrine. Similarly, receptor stimulation causes exit of the α_{1a}AR from light rafts within 3-10 min in contrast to the G proteins, which largely remain in light rafts. Importantly, this delayed exit of the α_{1a}AR suggests acute receptor signaling and desensitization occur entirely within rafts. Interestingly, both confocal analysis and measurement of surface α_{1a}AR levels indicate modest receptor internalization during the 10 min following stimulation, suggesting most of the receptor has entered non-raft plasma membrane. Nevertheless, activation does increase the rate of receptor internalization as does disruption of rafts with methyl-β-cyclodextrin, suggesting raft exit enables internalization. Confocal analysis of surface-labeled hemagglutinin-α_{1a}AR reveals that basal and stimulated receptor occupies clathrin pits in fixed cells consistent with previous indirect evidence. The evidence presented here strongly suggests the α_{1a}AR is a lipid raft protein under basal conditions and implies agonist-mediated signaling occurs from rafts.

3.1050 Epithelial polarity requires septin coupling of vesicle transport to polyglutamylated microtubules
Spiliotis, E.T., Hunt, S.J., Hu, Q., Kinoshita, M. And Nelson, W.J.
J. Cell Biol., ***180(2),*** *295-303 (2008)*

In epithelial cells, polarized growth and maintenance of apical and basolateral plasma membrane domains depend on protein sorting from the trans-Golgi network (TGN) and vesicle delivery to the plasma membrane. Septins are filamentous GTPases required for polarized membrane growth in budding yeast, but whether they function in epithelial polarity is unknown. Here, we show that in epithelial cells septin 2 (SEPT2) fibers colocalize with a subset of microtubule tracks composed of polyglutamylated (polyGlu) tubulin, and that vesicles containing apical or basolateral proteins exit the TGN along these SEPT2/polyGlu microtubule tracks. Tubulin-associated SEPT2 facilitates vesicle transport by maintaining polyGlu microtubule tracks and impeding tubulin binding of microtubule-associated protein 4 (MAP4). Significantly, this regulatory step is required for polarized, columnar-shaped epithelia biogenesis; upon SEPT2 depletion, cells become short and fibroblast-shaped due to intracellular accumulation of apical and basolateral membrane proteins, and loss of vertically oriented polyGlu microtubules. We suggest that

septin coupling of the microtubule cytoskeleton to post-Golgi vesicle transport is required for the morphogenesis of polarized epithelia.

3.1051 Dipeptidyl peptidase IV inhibition downregulates Na+-H+ exchanger NHE3 in rat renal proximal tubule

Castello, A. et al

Am. J. Physiol. Renal Physiol., ***294***, *F414-F422 (2008)*

In the microvillar microdomain of the kidney brush border, sodium hydrogen exchanger type 3 (NHE3) exists in physical complexes with the serine protease dipeptidyl peptidase IV (DPPIV). The purpose of this study was to explore the functional relationship between NHE3 and DPPIV in the intact proximal tubule in vivo. To this end, male Wistar rats were treated with an injection of the reversible DPPIV inhibitor Lys [$Z(NO_2)$]-pyrrolidide (I40; 60 $mg \cdot kg^{-1} \cdot day^{-1}$ ip) for 7 days. Rats injected with equal amounts of the noninhibitory compound Lys[$Z(NO_2)$]-OH served as controls. Na^+-H^+ exchange activity in isolated microvillar membrane vesicles was 45 ± 5% decreased in rats treated with I40. Membrane fractionation studies using isopycnic centrifugation revealed that I40 provoked redistribution of NHE3 along with a small fraction of DPPIV from the apical enriched microvillar membranes to the intermicrovillar microdomain of the brush border. I40 significantly increased urine output (67 ± 9%; $P < 0.01$), fractional sodium excretion (63 ± 7%; $P < 0.01$), as well as lithium clearance (81 ± 9%; $P < 0.01$), an index of end-proximal tubule delivery. Although not significant, a tendency toward decreased blood pressure and plasma pH/HCO_3^- was noted in I40-treated rats. These findings indicate that inhibition of DPPIV catalytic activity is associated with inhibition of NHE3-mediated $NaHCO_3$ reabsorption in rat renal proximal tubule. Inhibition of apical Na^+-H^+ exchange is due to reduced abundance of NHE3 protein in the microvillar microdomain of the kidney brush border. Moreover, this study demonstrates a physiologically significant interaction between NHE3 and DPPIV in the intact proximal tubule in vivo.

3.1052 Sphingolipid synthesis is necessary for kinetoplast segregation and cytokinesis in Trypanosoma brucei

Fridberg, A. et al

J. Cell Sci., ***121***, *522-535 (2008)*

Sphingolipids and their metabolites have been thought crucial for cell growth and cell cycle progression, membrane and protein trafficking, signal transduction, and formation of lipid rafts; however, recent studies in trypanosomes point to the dispensability of sphingolipids in some of these processes. In this study, we explore the requirements for de novo sphingolipid biosynthesis in the insect life cycle stage of the African trypanosome *Trypanosoma brucei* by inhibiting the enzyme serine palmitoyltransferase (SPT2) by using RNA interference or treatment with a potent SPT2 inhibitor myriocin. Mass spectrometry revealed that upon SPT2 inhibition, the parasites contained substantially reduced levels of inositolphosphorylceramide. Although phosphatidylcholine and cholesterol levels were increased to compensate for this loss, the cells were ultimately not viable. The most striking result of sphingolipid reduction in procyclic *T. brucei* was aberrant cytokinesis, characterized by incomplete cleavage-furrow formation, delayed kinetoplast segregation and emergence of cells with abnormal DNA content. Organelle replication continued despite sphingolipid depletion, indicating that sphingolipids act as second messengers regulating cellular proliferation and completion of cytokinesis. Distention of the mitochondrial membrane, formation of multilamellar structures within the mitochondrion and near the nucleus, accumulation of lipid bodies and, less commonly, disruption of the Golgi complex were observed after prolonged sphingolipid depletion. These findings suggest that some aspects of vesicular trafficking may be compromised. However, flagellar membrane targeting and the association of the flagellar membrane protein calflagin with detergent-resistant membranes were not affected, indicating that the vesicular trafficking defects were mild. Our studies indicate that sphingolipid biosynthesis is vital for cell cycle progression and cell survival, but not essential for the normal trafficking of flagellar membrane-associated proteins or lipid raft formation in procyclic *T. brucei*.

3.1053 Clustering endothelial E-selectin in clathrin-coated pits and lipid rafts enhances leukocyte adhesion under flow

Setiadi, H. and Mcever, R.P.

Blood, ***111(4)***, *1989-1998 (2008)*

During inflammation, E-selectin expressed on cytokine-activated endothelial cells mediates leukocyte rolling under flow. E-selectin undergoes endocytosis and may associate with lipid rafts. We asked whether distribution of E-selectin in membrane domains affects its functions. E-selectin was internalized in transfected CHO cells or cytokine-activated human umbilical vein endothelial cells (HUVECs). Confocal microscopy demonstrated colocalization of E-selectin with α-adaptin, a clathrin-associated protein. Deleting the cytoplasmic domain of E-selectin or disrupting clathrin-coated pits with hypertonic medium blocked internalization of E-selectin, reduced colocalization of E-selectin with α-adaptin, and inhibited E-selectin-mediated neutrophil rolling under flow. Unlike CHO cells, HUVECs expressed a small percentage of E-selectin in lipid rafts. Even fewer neutrophils rolled on E-selectin in HUVECs treated with hypertonic medium and with methyl-β-cyclodextrin, which disrupts lipid rafts. These data demonstrate that E-selectin clusters in both clathrin-coated pits and lipid rafts of endothelial cells but is internalized in clathrin-coated pits. Distribution in both domains markedly enhances E-selectin's ability to mediate leukocyte rolling under flow.

3.1054 **The Vaccinia Virus B5 Protein Requires A34 for Efficient Intracellular Trafficking from the Endoplasmic Reticulum to the Site of Wrapping and Incorporation into Progeny Virions**
Earley, A.K., Chan, W.M. and Ward, B.M.
J. Virol., ***82(5)***, *2161-2169 (2008)*

The glycoproteins encoded by the vaccinia virus A34R and B5R genes are involved in intracellular envelope virus formation and are highly conserved among orthopoxviruses. A recombinant virus that has the A34R gene deleted and the B5R gene replaced with a B5R gene fused to the enhanced green fluorescent protein (B5R-GFP) gene was created (vB5R-GFP/ΔA34R) to investigate the role of A34 during virion morphogenesis. Cells infected with vB5R-GFP/ΔA34R displayed GFP fluorescence throughout the cytoplasm, which differed markedly from that seen in cells infected with a normal B5R-GFP-expressing virus (vB5R-GFP). Immunofluorescence and subcellular fractionation demonstrated that B5-GFP localizes with the endoplasmic reticulum in the absence of A34. Expression of either full-length A34 or a construct consisting of the lumenal and transmembrane domains restored normal trafficking of B5-GFP to the site of wrapping in the juxtanuclear region. Coimmunoprecipitation studies confirmed that B5 and A34 interact through their luminal domains, and further analysis revealed that in the absence of A34, B5 is not efficiently incorporated into virions released from the cell.

3.1055 **Modulation of ileal bile acid transporter (ASBT) activity by depletion of plasma membrane cholesterol: association with lipid rafts**
Annaba, F. et al
Am. J. Physiol. Gastrointest. Liver Physiol., ***294***, *G489-G497 (2008)*

Apical sodium-dependent bile acid transporter (ASBT) represents a highly efficient conservation mechanism of bile acids via mediation of their active transport across the luminal membrane of terminal ileum. To gain insight into the cellular regulation of ASBT, we investigated the association of ASBT with cholesterol and sphingolipid-enriched specialized plasma membrane microdomains known as lipid rafts and examined the role of membrane cholesterol in maintaining ASBT function. Human embryonic kidney (HEK)-293 cells stably transfected with human ASBT, human ileal brush-border membrane vesicles, and human intestinal epithelial Caco-2 cells were utilized for these studies. Floatation experiments on **Optiprep** density gradients demonstrated the association of ASBT protein with lipid rafts. Disruption of lipid rafts by depletion of membrane cholesterol with methyl-β-cyclodextrin (MβCD) significantly reduced the association of ASBT with lipid rafts, which was paralleled by a decrease in ASBT activity in Caco-2 and HEK-293 cells treated with MβCD. The inhibition in ASBT activity by MβCD was blocked in the cells treated with MβCD-cholesterol complexes. Kinetic analysis revealed that MβCD treatment decreased the V_{max} of the transporter, which was not associated with alteration in the plasma membrane expression of ASBT. Our study illustrates that cholesterol content of lipid rafts is essential for the optimal activity of ASBT and support the association of ASBT with lipid rafts. These findings suggest a novel mechanism by which ASBT activity may be rapidly modulated by alterations in cholesterol content of plasma membrane and thus have important implications in processes related to maintenance of bile acid and cholesterol homeostasis.

3.1056 **Ceramide kinase promotes Ca2+ signaling near IgG-opsonized targets and enhances phagolysosomal fusion in COS-1 cells**
Hinkovska-Galcheva, V. et al
J. Lipid Res., ***49***, *531-542 (2008)*

Ceramide-1-phosphate (C1P) is a novel bioactive sphingolipid formed by the phosphorylation of ceramide catalyzed by ceramide kinase (CERK). In this study, we evaluated the mechanism by which increased C1P during phagocytosis enhances phagocytosis and phagolysosome formation in COS-1 cells expressing hCERK. Stable transfectants of COS-1 cells expressing FcγRIIA or both FcγRIIA/hCERK expression vectors were created. Cell fractionation studies demonstrated that hCERK and the transient receptor potential channel (TRPC-1) were enriched in caveolae fractions. Our data establish that both CERK and TRPC-1 localize to the caveolar microdomains during phagocytosis and that CERK also colocalizes with EIgG in FcγRIIA/hCERK-bearing COS-1 cells. Using high-speed fluorescence microscopy, FcγRIIA/hCERK transfected cells displayed Ca^{2+} sparks around the phagosome. In contrast, cells expressing FcγRIIA under identical conditions displayed little periphagosomal Ca^{2+} signaling. The enhanced Ca^{2+} signals were accompanied by enhanced phagolysosome formation. However, the addition of pharmacological reagents that inhibit store-operated channels (SOCs) reduced the phagocytic index and phagolysosomal fusion in hCERK transfected cells. The higher Ca^{2+} signal observed in hCERK transfected cells as well as the fact that CERK colocalized with EIgG during phagocytosis support our hypothesis that Ca^{2+} signaling is an important factor for increasing phagocytosis and is regulated by CERK in a manner that involves SOCs/TRPCs.

3.1057 Cross-talk between PDGF and S1P signalling elucidates the inhibitory effect and potential antifibrotic action of the immunomodulator FTY720 in activated HSC-cultures
Brunati, A.M. et al
*Biochim. Biophys. Acta, **1783**, 347-359 (2008)*

Platelet-derived growth factor (PDGF) has been shown to be essential in the activation of hepatic stellate cells (HSCs), contributing to the onset and development of hepatic fibrosis. Recently, sphingosine-1-phosphate (S1P) has been shown to be a mitogen and stimulator of chemotaxis also for HSCs. Since it has been demonstrated in several cell types that cross-talk between PDGF and S1P signalling pathways occurs, our aim was to investigate the potential antifibrotic effect of FTY720, whose phosphorylated form acts as a potent S1P receptor (S1PR) modulator, on HSCs. FTY720 inhibits cell proliferation and migration after PDGF stimulation on HSCs in a concentration range between 0.1 and 1 μM. By using compounds that block S1P signalling (PTX and VPC23019), we assessed that FTY720 also acts in an S1P receptor-independent way by decreasing the level of tyrosine phosphorylation of PDGF receptor, with subsequent inhibition of the PDGF signalling pathway. In addition, inhibition of sphingosine kinase2 (SphK2), which is responsible for FTY720 phosphorylation, by DMS/siRNA unveils a mechanism of action irrespective of its phosphorylation, in particular decreasing the level of $S1P_1$ on the plasma membrane. These findings led us to hypothesize a potential use of FTY720 as a potential antifibrotic drug for further clinical application.

3.1058 Lipid rafts regulate ethanol-induced activation of TLR4 signaling in murine macrophages
Fernandez-Lizarbe, S., Pascual, M., Soledad Gascon, M., Blanco, A. and Guerri, C.
*Mol. Immunol., **45**, 2007-2016 (2008)*

Toll-like receptors (TLRs) response is critical in innate resistance to infection. Alcohol consumption has been shown to suppress the inflammatory response mediated through TLR4, down regulating the production of inflammatory cytokines. We recently reported that low concentrations of ethanol activate TLR4 signaling in astrocytes and triggers neuroinflammation. Because macrophages are important cells in innate immunity, we investigate whether low concentrations of ethanol could stimulate the TLR4 signaling response in murine RAW 264.7 macrophages, and the mechanism involved in the ethanol-induced TLR4 activation. Our results show that while ethanol, at high concentrations (100 mM) or in the presence of the LPS, suppresses the TLR4 response, low to moderate levels (10–50 mM) activate the TLR4 response and triggers the stimulation of the mitogen-activated protein kinases (MAPKs) and the transcription factor NF-κB pathways, leading to the production of nitric oxide (NO) and inflammatory cytokines. Pre-treatment with anti-TLR4 Abs abolishes the effects of ethanol on the production of cytokines. We also present evidence that stimulation with either ethanol or LPS induces translocation and clustering of TLR4 and signaling molecules (IRAK and MAPKs) into lipid rafts. Treatment with either streptolysin-O or saponin, lipid rafts disrupting agents, abolishes the ethanol-induced activation of the TLR4/IL-1RI signaling pathway. In summary, the present results demonstrate that low to moderate concentrations of ethanol are capable of stimulating TLR4/IL-1RI response, and provide evidence of a novel mechanism by which ethanol, through its interaction with membrane rafts, can promote TLR4/IL-1RI recruitment and signaling.

3.1059 Human Immunodeficiency Virus Type 1 Nef Recruits the Guanine Exchange Factor Vav1 via an Unexpected Interface into Plasma Membrane Microdomains for Association with p21-Activated Kinase 2 Activity
Rauch, S., Pulkkinen, K., Saksela, K. And Fackler, O.T.
J. Virol., ***82(6)***, *2918-2929 (2008)*

Alterations of T-cell receptor signaling by human immunodeficiency virus type 1 (HIV-1) Nef involve its association with a highly active subpopulation of p21-activated kinase 2 (PAK2) within a dynamic signalosome assembled in detergent-insoluble membrane microdomains. Nef-PAK2 complexes contain the GTPases Rac and Cdc42 as well as a factor providing guanine nucleotide exchange factor (GEF) activity for Rac/Cdc42. However, the identity of this GEF has remained controversial. Previous studies suggested the association of Nef with at least three independent GEFs, Vav, DOCK2/ELMO1, and βPix. Here we used a broad panel of approaches to address which of these GEFs is involved in the functional interaction of Nef with PAK2 activity. Biochemical fractionation and confocal microscopy revealed that Nef recruits Vav1, but not DOCK2/ELMO1 or βPix, to membrane microdomains. Transient RNAi knockdown, analysis of cell lines defective for expression of Vav1 or DOCK2 as well as use of a βPix binding-deficient PAK2 variant confirmed a role for Vav1 but not DOCK2 or βPix in Nef's association with PAK2 activity. Nef-mediated microdomain recruitment of Vav1 occurred independently of the Src homology 3 domain binding PxxP motif, which is known to connect Nef to many cellular signaling processes. Instead, a recently described protein interaction surface surrounding Nef residue F195 was identified as critical for Nef-mediated raft recruitment of Vav1. These results identify Vav1 as a relevant component of the Nef-PAK2 signalosome and provide a molecular basis for the role of F195 in formation of a catalytically active Nef-PAK2 complex.

3.1060 Signal sequence- and translation-independent mRNA localization to the endoplasmic reticulum
Pyhtila, B. et al
RNA, ***14***, *445-453 (2008)*

The process of mRNA localization typically utilizes *cis*-targeting elements and *trans*-recognition factors to direct the compartmental organization of translationally suppressed mRNAs. mRNA localization to the endoplasmic reticulum (ER), in contrast, occurs via a co-translational, signal sequence/signal recognition particle (SRP)-dependent mechanism. We have utilized cell fractionation/cDNA microarray analysis, shRNA-mediated suppression of SRP expression, and mRNA reporter construct studies to define the role of the SRP pathway in ER-directed mRNA localization. Cell fractionation studies of mRNA partitioning between the cytosol and ER demonstrated the expected enrichment of cytosolic/nucleoplasmic protein-encoding mRNAs and secretory/integral membrane protein-encoding mRNAs in the cytosol and ER fractions, respectively, and identified a subpopulation of cytosolic/nucleoplasmic protein-encoding mRNAs in the membrane-bound mRNA pool. The latter finding suggests a signal sequence-independent pathway of ER-directed mRNA localization. Extending from these findings, mRNA partitioning was examined in stable SRP54 shRNA knockdown HeLa cell lines. shRNA-directed reductions in SRP did not globally alter mRNA partitioning patterns, although defects in membrane protein processing were observed, further suggesting the existence of multiple pathways for mRNA localization to the ER. ER localization of GRP94-encoding mRNA was observed when translation was disabled by mutation of the start codon/insertion of a 5'UTR stem–loop structure or upon deletion of the encoded signal sequence. Combined, these data indicate that the mRNA localization to the ER can be conferred independent of the signal sequence/SRP pathway and suggest that mRNA localization to the ER may utilize *cis*-encoded targeting information.

3.1061 Myo2p, a class V myosin in budding yeast, associates with a large ribonucleic acid–protein complex that contains mRNAs and subunits of the RNA-processing body
Chang, W. et al
RNA, ***14***, *491-502 (2008)*

Myo2p is an essential class V myosin in budding yeast with several identified functions in organelle trafficking and spindle orientation. The present study demonstrates that Myo2p is a component of a large RNA-containing complex (Myo2p–RNP) that is distinct from polysomes based on sedimentation analysis and lack of ribosomal subunits in the Myo2p–RNP. Microarray analysis of RNAs that coimmunoprecipitate with Myo2p revealed the presence of a large number of mRNAs in this complex. The Myo2p–RNA complex is in part composed of the RNA processing body (P-body) based on coprecipitation with P-body protein subunits and partial colocalization of Myo2p with P-bodies. P-body disassembly is

delayed in the motor mutant, *myo2-66*, indicating that Myo2p may facilitate the release of mRNAs from the P-body.

3.1062 Protein quality control: the who's who, the where's and therapeutic escapes
Roth, J. et al
Histochem. Cell Biol., ***129***, *163-177 (2008)*

In cells the quality of newly synthesized proteins is monitored in regard to proper folding and correct assembly in the early secretory pathway, the cytosol and the nucleoplasm. Proteins recognized as non-native in the ER will be removed and degraded by a process termed ERAD. ERAD of aberrant proteins is accompanied by various changes of cellular organelles and results in protein folding diseases. This review focuses on how the immunocytochemical labeling and electron microscopic analyses have helped to disclose the in situ subcellular distribution pattern of some of the key machinery proteins of the cellular protein quality control, the organelle changes due to the presence of misfolded proteins, and the efficiency of synthetic chaperones to rescue disease-causing trafficking defects of aberrant proteins.

3.1063 Insulin Internalizes GLUT2 in the Enterocytes of Healthy but Not Insulin-Resistant Mice
Tobin, V. et al
Diabetes, ***57***, *555-562 (2008)*

OBJECTIVES—A physiological adaptation to a sugar-rich meal is achieved by increased sugar uptake to match dietary load, resulting from a rapid transient translocation of the fructose/glucose GLUT2 transporter to the brush border membrane (BBM) of enterocytes. The aim of this study was to define the contributors and physiological mechanisms controlling intestinal sugar absorption, focusing on the action of insulin and the contribution of GLUT2-mediated transport.
RESEARCH DESIGN AND METHODS—The studies were performed in the human enterocytic colon carcinoma TC7 subclone (Caco-2/TC7) cells and in vivo during hyperinsulinemic-euglycemic clamp experiments in conscious mice. Chronic high-fructose or high-fat diets were used to induce glucose intolerance and insulin resistance in mice.
RESULTS AND CONCLUSIONS—In Caco-2/TC7 cells, insulin action diminished the transepithelial transfer of sugar and reduced BBM and basolateral membrane (BLM) GLUT2 levels, demonstrating that insulin can target sugar absorption by controlling the membrane localization of GLUT2 in enterocytes. Similarly, in hyperinsulinemic-euglycemic clamp experiments in sensitive mice, insulin abolished GLUT2 (i.e., the cytochalasin B-sensitive component of fructose absorption), decreased BBM GLUT2, and concomitantly increased intracellular GLUT2. Acute insulin treatment before sugar intake prevented the insertion of GLUT2 into the BBM. Insulin resistance in mice provoked a loss of GLUT2 trafficking, and GLUT2 levels remained permanently high in the BBM and low in the BLM. We propose that, in addition to its peripheral effects, insulin inhibits intestinal sugar absorption to prevent excessive blood glucose excursion after a sugar meal. This protective mechanism is lost in the insulin-resistant state induced by high-fat or high-fructose feeding.

3.1064 Phospholipid actions on PGHS-1 and -2 cyclooxygenase kinetics
Doyen, J.R., Yucer, N., Lichtenberger, L.M. and Kulmacz, R.J.
Prostaglandins & Other Lipid Mediators, ***85(3-4)***, *134-143 (2008)*

Cyclooxygenase (COX) catalysis by prostaglandin H synthase (PGHS) is a key control step for regulation of prostanoid biosynthesis. Both PGHS isoforms are integral membrane proteins and their substrate fatty acids readily partition into membranes, but the impact of phospholipids and lipid membranes on COX catalysis and the actions of COX inhibitors are not well understood. We have characterized the COX kinetics and ibuprofen inhibition of the purified PGHS isoforms in the presence of phosphatidylcholine (PC) with varying acyl chain structure and physical state. PC was found to directly inhibit COX activity, with non-competitive inhibition by PC monomers binding away from the COX active site and competitive inhibition by micellar/bilayer forms of PC due to sequestration of the arachidonate substrate. Competitive inhibition by native membranes was observed in a comparison of COX kinetics in sheep seminal vesicle microsomes before and after solubilization of PGHS-1. PC liposomes significantly increase the inhibitory potency of ibuprofen against both PGHS isoforms without changing the reversible character of ibuprofen action or requiring binding of PGHS to the liposomes. These results suggest a useful conceptual framework for analyzing the complex interactions among the PGHS proteins, substrates, inhibitors and phospholipid.

3.1065 Multiple functions of ergosterol in the fission yeast Schizosaccharomyces pombe
Iwaki, T. et al
*Microbiology, **154**, 830-841 (2008)*

Sterols are a major class of membrane lipids in eukaryotes. In *Schizosaccharomyces pombe*, sterol 24-C-methyltransferase (Erg6p), C-8 sterol isomerase (Erg2p), C-5 sterol desaturase (Erg31p, Erg32p), C-22 sterol desaturase (Erg5p) and C-24 (28) sterol reductase (Sts1p/Erg4p) have been predicted, but not yet determined, to catalyse a sequence of reactions from zymosterol to ergosterol. Disruption mutants of these genes were unable to synthesize ergosterol, and most were tolerant to the polyene drugs amphotericin B and nystatin. Disruption of *erg31*$^{+}$ or *erg32*$^{+}$ did not cause ergosterol deficiency or tolerance to polyene drugs, indicating that the two C-5 sterol desaturases have overlapping functions. GFP-tagged DRM (detergent-resistant membrane)-associated protein Pma1p localized to the plasma membrane in *erg*Δ mutants. DRM fractionation revealed that the association between Pma1-GFP and DRM was weakened in *erg6*Δ but not in other *erg* mutants. Several GFP-tagged plasma membrane proteins were tested, and an amino acid permease homologue, SPBC359.03c, was found to mislocalize to intracellular punctate structures in the *erg*Δ mutants. These results indicate that these proteins are responsible for ergosterol biosynthesis in fission yeast, similar to the situation in *Saccharomyces cerevisiae*. Furthermore, in fission yeast, ergosterol is important for plasma membrane structure and function and for localization of plasma membrane proteins.

3.1066 CFTR in a lipid raft-TNFR1 complex modulates gap junctional intercellular communication and IL-8 secretion
Dudez, T. et al
*Eur. J. Lab. Invest., **38(Suppl.1-2)**, 20, abstract 54*

Background: Mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) cause a chronic inflammatory response in the lung of patients with Cystic Fibrosis (CF). Defect in TNF-a signaling through the Src family tyrosine kinases (SFKs) has been reported in CF cells, and shown to unable the regulation of gap junctional communication (GJIC). Here, we sought to elucidate the mechanisms linking TNF-a signaling to the functions of CFTR at the molecular level. Materials and methods: Detergent-resistant membran microdomains
(DRMs), or lipid rafts, were isolated using the Optiprep method from MDCKI cells expressing wild-type (WtCFTR) or mutant CFTR lacking its PDZ-interacting motif (CFTR-aTRL), and from the human glandular Calu-3 cell line endogenously expressing CFTR. GJIC was evaluated by dye coupling and IL-8 secretion by dot blots.
Results: TNF-a increased the amount of Wt-CFTR but not CFTR-aTRL in DRMs. This recruitment was modulated by SFK activity and associated with DRM localization of TNFR1 and c-Src. Activation of TNFR1 signaling also decreased GJIC and markedly stimulated IL-8 production in WtCFTR cells. The absence of CFTR in DRMs was associated with abnormal TNFR1 signaling as revealed by no recruitment of TNFR1 and c-Src to lipid rafts in CFTR-aTRL cells and loss of regulation of GJIC and IL-8 secretion. We further show in Calu-3 cells that endogen CFTR is present at the cell surface in DRMs, which amount is enhanced by TNF-a and contributes to IL-8 secretion. Conclusions: Localization of CFTR to lipid rafts in association with c-Src and TNFR1 provides a responsive signaling complex to regulate GJIC and cytokine signaling. Disruption of
CFTR interactions with component of this complex may lead to abnormalities relevant for the CF pathogenesis.

3.1067 A Lipid-mediated Quality Control Process in the Golgi Apparatus in Yeast
Pineau, L. et al
*Mol. Biol. Cell, **9**, 807-821 (2008)*

When heme biosynthesis is disrupted, the yeast *Saccharomyces cerevisiae* becomes unable to synthesize its major sterol, ergosterol, and desaturate fatty acids. We took advantage of this physiological peculiarity to evaluate the consequences of ergosterol and/or unsaturated fatty acid (UFA) depletions on the biogenesis of a model polytopic plasma membrane protein, the uracil permease Fur4p. We show that under UFA shortage, which results in low amounts of diunsaturated phospholipid species, and under ergosterol depletion, Fur4p is prematurely routed from the Golgi apparatus to the vacuolar lumen in a process that requires the ubiquitin ligase Rsp5p. Interestingly, this diversion is not correlated to Fur4p exclusion from detergent-resistant membranes. In an independent set of experiments, we show that Fur4p targeting to the plasma membrane depends on phosphatidylethanolamine amounts and more specifically on the propensity

of this phospholipid to form a hexagonal phase. In light of recent literature, we propose a model in which ergosterol and diunsaturated phospholipid species maintain optimal membrane curvature for Fur4p to evade the Golgi quality control process and to be properly delivered to its normal destination.

3.1068 Phospholipid and glycolipid composition of acidocalcisomes of Trypanosoma cruzi
Salto, M.L., Kuhlenschmidt, T., Kuhlenschmidt, M., de Lederkremer, R.M. and Docampo, R.
*Mol. Biochem. Parasitol., **158**, 120-130 (2008)*

Highly purified acidocalcisomes from *Trypanosoma cruzi* epimastigotes were obtained by differential centrifugation and iodixanol gradient ultracentrifugation. Lipid analysis of acidocalcisomes revealed the presence of low amounts of 3β-hydroxysterols and predominance of phospholipids. Alkylacyl phosphatidylinositol (16:0/18:2), diacyl phosphatidylinositol (18:0/18:2), diacyl phosphatidylcholine (16:0/18:2; 16:1/18:2; 16:2/18:2; 18:1/18:2 and 18:2/18:2), and diacyl phosphatidylethanolamine (16:0/18:2 and 16:1/18:2) were the only phospholipids characterized by electrospray ionization-mass spectrometry (ESI-MS). Incubation of epimastigotes with [^{3}H]-mannose and isolation of acidocalcisomes allowed the detection of a glycoinositolphospholipid (GIPL) in these organelles. The sugar content of the acidocalcisomal GIPL was similar to that of the GIPL present in a microsomal fraction but the amount of galactofuranose and inositol with respect to the other monosaccharides was lower, suggesting a different chemical structure. Taken together, these results indicate that acidocalcisomes of *T. cruzi* have a distinct lipid and carbohydrate composition.

3.1069 FcγRI (CD64) resides constitutively in lipid rafts
Beekman, J.M., van der Linden, J.A., van de Winkel, J.G.J. and Leusen, J.H.W.
*Immunol. Lett., **116**, 149-155 (2008)*

Cellular membranes contain microdomains known as 'lipid rafts' or detergent-insoluble microdomains (DRM), enriched in cholesterol and sphingolipids. DRM can play an important role in many cellular processes, including signal transduction, cytoskeletal organization, and pathogen entry. Many receptors like T cell receptors, B cell receptors and IgE receptors have been shown to reside in DRM. The majority of these receptors depend on multivalent ligand interaction to associate with these microdomains. We, here, study association between the high affinity IgG receptor, FcγRI (CD64), and membrane microdomains. FcγRI is a 72 kDa type I glycoprotein that can mediate phagocytosis of opsonized pathogens, but can also effectively capture small immune complexes, and facilitates antigen presentation. We found FcγRI to predominantly reside within detergent-insoluble buoyant membranes, together with FcRγ-chain, but independent of cross-linking ligand. With the use of confocal imaging, FcγRI was found to co-patch with GM1, a microdomain-enriched glycolipid. Depletion of cellular cholesterol, furthermore, modulated FcγRI–ligand interactions. These data indicated FcγRI to reside within lipid rafts without prior triggering of the receptor.

3.1070 Selective association of misfolded ALS-linked mutant SOD1 with the cytoplasmic face of mitochondria
Vande Velde, C., Miller, T.M., Cashman, N.R. and Cleveland, D.W.
*PNAS, **105(10)**, 4022-4027 (2008)*

Mutations in copper/zinc superoxide dismutase (SOD1) are causative for dominantly inherited amyotrophic lateral sclerosis (ALS). Despite high variability in biochemical properties among the disease-causing mutants, a proportion of both dismutase-active and -inactive mutants are stably bound to spinal cord mitochondria. This mitochondrial proportion floats with mitochondria rather than sedimenting to the much higher density of protein, thus eliminating coincidental cosedimentation of protein aggregates with mitochondria. Half of dismutase-active and ≈90% of dismutase-inactive mutant SOD1 is bound to mitochondrial membranes in an alkali- and salt-resistant manner. Sensitivity to proteolysis and immunoprecipitation with an antibody specific for misfolded SOD1 demonstrate that in all mutant SOD1 models, misfolded SOD1 is deposited onto the cytoplasmic face of the outer mitochondrial membrane, increasing antigenic accessibility of the normally structured electrostatic loop. Misfolded mutant SOD1 binding is both restricted to spinal cord and selective for mitochondrial membranes, implicating exposure to mitochondria of a misfolded mutant SOD1 conformer mediated by a unique, tissue-selective composition of cytoplasmic chaperones, components unique to the cytoplasmic face of spinal mitochondria to which misfolded SOD1 binds, or misfolded SOD1 conformers unique to spinal cord that have a selective affinity for mitochondrial membranes.

3.1071 **Carboxypeptidase M and Kinin B1 Receptors Interact to Facilitate Efficient B1 Signaling from B2 Agonists**
Zhang, X., Tan, F., Zhang, Y. And Skidgel, R.
J. Biol. Chem., ***283(12)***, *7994-8004 (2008)*

Kinin B1 receptor (B1R) expression is induced by injury or inflammatory mediators, and its signaling produces both beneficial and deleterious effects. Kinins cleaved from kininogen are agonists of the B2R and must be processed by a carboxypeptidase to generate B1R agonists des-Arg^{9}-bradykinin or des-Arg^{10}-kallidin. Carboxypeptidase M (CPM) is a membrane protein potentially well suited for this function. Here we show that CPM expression is required to generate a B1R-dependent increase in $[Ca^{2+}]_i$ in cells stimulated with B2R agonists kallidin or bradykinin. CPM and the B1R interact on the cell membrane, as shown by co-immunoprecipitation, cross-linking, and fluorescence resonance energy transfer analysis. CPM and B1R are also co-localized in lipid raft/caveolin-enriched membrane fractions, as determined by gradient centrifugation. Treatment of cells co-expressing CPM and B1R with methyl-β-cyclodextrin to disrupt lipid rafts reduced the B1R-dependent increase in $[Ca^{2+}]_i$ in response to B2R agonists, whereas cholesterol treatment enhanced the response. A monoclonal antibody to the C-terminal β-sheet domain of CPM reduced the B1R response to B2R agonists without inhibiting CPM. Cells expressing a novel fusion protein containing CPM at the N terminus of the B1R also increased $[Ca^{2+}]_i$ when stimulated with B2R agonists, but the response was not reduced by methyl-β-cyclodextrin or CPM antibody. A B1R- and CPM-dependent calcium signal in response to B2R agonist bradykinin was also found in endothelial cells that express both proteins. Thus, a close relationship of B1Rs and CPM on the membrane is required for efficiently generating B1R signals, which play important roles in inflammation.

3.1072 **Over-expression of mammalian sialidase NEU3 reduces Newcastle disease virus entry and propagation in COS7 cells**
Anastasia, L. et al
Biochim. Biophys. Acta, ***1780(3)***, *504-512 (2008)*

The paramyxovirus Newcastle Disease Virus (NDV) binds to sialic acid-containing glycoconjugates, sialoglycoproteins and sialoglycolipids (gangliosides) of host cell plasma membrane through its hemagglutinin-neuraminidase (sialidase) HN glycoprotein. We hypothesized that the modifications of the cell surface ganglioside pattern determined by over-expression of the mammalian plasma-membrane associated, ganglioside specific, sialidase NEU3 would affect the virus-host cell interactions. Using COS7 cells as a model system, we observed that over-expression of the murine MmNEU3 did not affect NDV binding but caused a marked reduction in NDV infection and virus propagation through cell–cell fusion. Moreover, since GD1a was greatly reduced in COS7 cells following NEU3-over-expression, we added [^{3}H]-labelled GD1a to COS7 cells under conditions that block intralysosomal metabolic processing, and we observed a marked increase of GD1a cleavage to GM1 during NDV infection, indicating a direct involvement of the virus sialidase and host cell GD1a in NDV infectivity. Therefore, the decrease of GD1a in COS7 cell membrane upon MmNEU3 over-expression is likely to be instrumental to NDV reduced infection. Evidence was also provided for the preferential association of NDV-HN at 4 °C to detergent resistant microdomains (DRMs) of COS7 cells plasma membranes.

3.1073 **Fractionation of Subcellular Membrane Vesicles of Epithelial and Nonepithelial Cells by OptiPrep™ Density Gradient Ultracentrifugation**
Li, X. and Donowitz, M.
Methods Mol. Biol., ***440***, *97-110 (2008)*

Density gradient ultracentrifugation (DGUC) is widely used for physical isolation (enrichment rather than purification) of subcellular membrane vesicles. It has been a valuable tool to study specific subcellular localization and dynamic trafficking of proteins. While sucrose has been the main component of density gradients, a few years ago synthetic OptiPrep™ (iodixanol) began being used for separation of organelles because of its iso-osmotic property. Here, we describe a detailed protocol for density gradient fractionation of various mammalian subcellular vesicles, including endoplasmic reticulum (ER), Golgi apparatus, endosomes, and lipid rafts, as well as apical and basolateral membranes of polarized epithelial cells.

3.1074 **Determination of Genuine Residents of Plant Endomembrane Organelles using Isotope Tagging and Multivariate Statistics**
Lilley, K.S. and Dunkley, T.P.J.
Methods Mol. Biol., ***432***, *373-387 (2008)*

The knowledge of the localization of proteins to a particular subcellular structure or organelle is an important step towards assigning function to proteins predicted by genome-sequencing projects that have yet to be characterized. Moreover, the localization of novel proteins to organelles also enhances our understanding of the functions of organelles. Many organelles cannot be purified. In several cases where the degree of contamination by organelles with similar physical parameters to the organelle being studied has gone unchecked, this has lead to the mis-localization of proteins. Recently, several techniques have emerged, which depend on characterization of the distribution pattern of organelles partially separated using density centrifugation by quantitative proteomics approaches. Here, we discuss one of these approaches, the localization of organelle proteins by isotope tagging (LOPIT) where the distribution patterns of organelles are assessed by measuring the relative abundance of proteins between fractions along the length of density gradients using stable isotope-coded tags. The subcellular localizations of proteins can be determined by comparing their distributions to those of previously localized proteins by assuming that proteins that belong to the same organelle will cofractionate in density gradients. Analysis of distribution patterns can be achieved by employing multivariate statistical methods such as principal component analysis and partial least squares discriminate analysis. In this chapter, we focus on the use of the LOPIT technique in the assignment of membrane proteins to the plant Golgi apparatus and endoplasmic reticulum.

3.1075 Quantitative Proteomic Analysis to Profile Dynamic Changes in the Spatial Distribution of Cellular Proteins

Yan, W., Hwang, D. and Aebersold, R.
Methods Mol. Biol., ***432****, 389-401 (2008)*

Organelle protein profiles have traditionally been analyzed by subcellular fractionation of a specific organelle followed by the identification of the protein components of specific fractions containing the target organelle(s) using mass spectrometry (MS). However, because of limited resolution of the available fractionation methods, it is often difficult to isolate and thus profile pure organelles. Furthermore, many proteins (e.g., secretory proteins) are often observed to dynamically shuttle between organelles. Therefore, the determination of their true cellular localization requires the concurrent analysis of multiple organelles from the same cell lysate. Here, we report an integrated experimental approach that simultaneously profiles multiple organelles. It is based on the subcellular fractionation of cell lysates by density gradient centrifugation, iTRAQ labeling, and MS analysis of the proteins in selected fractions and principal component analysis (PCA) of the resulting quantitative proteomic data. Quantitative signature patterns of several organelles, including the ribosome, mitochondria, proteasome, lysosome, endoplasmic reticulum (ER), and Golgi apparatus, have been acquired from a single multiplexed proteomic assay using iTRAQ reagents. Through comparison PCA, we compare organelle profiles from cells under different physiological conditions to investigate changes in organelle profiles between control and perturbed samples. Such quantitative proteomics-based subcellular profiling methods thus provide useful tools to dissect the organization of cellular proteins into functional units and to detect dynamic changes in their protein composition.

3.1076 Free Flow Isoelectric Focusing
A Method for the Separation of Both Hydrophilic and Hydrophobic Proteins of Rat Liver Peroxisomes

Islinger, M. and Weber, G.
Methods Mol. Biol., ***432****, 199-215 (2008)*

Peroxisomes take part in various metabolic pathways related to the regulation of lipid homeostasis. Although detailed information on the enzymes involved in the peroxisomal lipid metabolism was acquired in the past, the mechanisms of metabolic exchange between peroxisomes and the cytosol or other organelles still remain an enigma. Therefore, a detailed analysis of the peroxisomal membrane proteome could help identify potential metabolite transporters. However, because of their highly hydrophobic character, membrane proteins tend to precipitate in aqueous media, making their fractionation still a challenging task. To overcome these obstacles, we have elaborated a protocol for the separation of both hydrophilic as well as hydrophobic proteins using free flow isoelectric focusing (FF-IEF). Similar to traditional gel-based isoelectric focusing, a denaturing electrophoresis buffer containing a mixture of urea, thiourea and detergents is applied to keep highly hydrophobic proteins in solution. Electrophoresis is conducted on a BD Free Flow Electrophoresis System with a linear pH gradient from 3 to 10 and sampled into 96 fractions. As a second dimension, sodium dodecyl sulphate–polyacrylamide gel electrophoresis (SDS–PAGE) is used to further separate and visualize the protein pattern of the peroxisomal subfractions

of matrix, peripheral and integral membrane proteins. The identification of the known peroxisomal membrane proteins PMP22, PMP70 as well as mGST in the subsequent matrix-assisted laser desorption ionization time of flight mass spectrometry (MALDI-TOF MS) analysis of the 100 most prominent protein bands has documented the suitability of this new technique for the analysis of hydrophobic proteins.

3.1077 Sequencing and analysis of the gene-rich space of cowpea
Timko, M.P. et al
*BMC Genomics, **9**, 103-122 (2008)*

Background
Cowpea, *Vigna unguiculata* (L.) Walp., is one of the most important food and forage legumes in the semi-arid tropics because of its drought tolerance and ability to grow on poor quality soils. Approximately 80% of cowpea production takes place in the dry savannahs of tropical West and Central Africa, mostly by poor subsistence farmers. Despite its economic and social importance in the developing world, cowpea remains to a large extent an underexploited crop. Among the major goals of cowpea breeding and improvement programs is the stacking of desirable agronomic traits, such as disease and pest resistance and response to abiotic stresses. Implementation of marker-assisted selection and breeding programs is severely limited by a paucity of trait-linked markers and a general lack of information on gene structure and organization. With a nuclear genome size estimated at ~620 Mb, the cowpea genome is an ideal target for reduced representation sequencing.
Results
We report here the sequencing and analysis of the gene-rich, hypomethylated portion of the cowpea genome selectively cloned by methylation filtration (MF) technology. Over 250,000 gene-space sequence reads (GSRs) with an average length of 610 bp were generated, yielding ~160 Mb of sequence information. The GSRs were assembled, annotated by BLAST homology searches of four public protein annotation databases and four plant proteomes (*A. thaliana*, *M. truncatula*, *O. sativa*, and *P. trichocarpa*), and analyzed using various domain and gene modeling tools. A total of 41,260 GSR assemblies and singletons were annotated, of which 19,786 have unique GenBank accession numbers. Within the GSR dataset, 29% of the sequences were annotated using the Arabidopsis Gene Ontology (GO) with the largest categories of assigned function being catalytic activity and metabolic processes, groups that include the majority of cellular enzymes and components of amino acid, carbohydrate and lipid metabolism. A total of 5,888 GSRs had homology to genes encoding transcription factors (TFs) and transcription associated factors (TAFs) representing about 5% of the total annotated sequences in the dataset. Sixty-two (62) of the 64 well-characterized plant transcription factor (TF) gene families are represented in the cowpea GSRs, and these families are of similar size and phylogenetic organization to those characterized in other plants. The cowpea GSRs also provides a rich source of genes involved in photoperiodic control, symbiosis, and defense-related responses. Comparisons to available databases revealed that about 74% of cowpea ESTs and 70% of all legume ESTs were represented in the GSR dataset. As approximately 12% of all GSRs contain an identifiable simple-sequence repeat, the dataset is a powerful resource for the design of microsatellite markers.
Conclusion
The availability of extensive publicly available genomic data for cowpea, a non-model legume with significant importance in the developing world, represents a significant step forward in legume research. Not only does the gene space sequence enable the detailed analysis of gene structure, gene family organization and phylogenetic relationships within cowpea, but it also facilitates the characterization of syntenic relationships with other cultivated and model legumes, and will contribute to determining patterns of chromosomal evolution in the Leguminosae. The micro and macrosyntenic relationships detected between cowpea and other cultivated and model legumes should simplify the identification of informative markers for marker-assisted trait selection and map-based gene isolation necessary for cowpea improvement.

3.1078 Endosomal NADPH oxidase regulates c-Src activation following hypoxia/reoxygenation injury
Li, Q., Zhang, Y., Marden, J.J., Banf, B. And Engelhardt, J.F.
*Biochem. J., **411**, 531-541 (2008)*

c-Src has been shown to activate NF-κB (nuclear factor κB) following H/R (hypoxia/reoxygenation) by acting as a redox-dependent IκBα (inhibitory κB) tyrosine kinase. In the present study, we have investigated the redox-dependent mechanism of c-Src activation following H/R injury and found that ROS (reactive oxygen species) generated by endosomal Noxs (NADPH oxidases) are critical for this process. Endocytosis following H/R was required for the activation of endosomal Noxs, c-Src activation, and the ability of c-Src to tyrosine-phosphorylate IκBα. Quenching intra-endosomal ROS during reoxygenation inhibited c-Src activation without affecting c-Src recruitment from the plasma membrane to endosomes. However, siRNA (small interfering RNA)-mediated knockdown of Rac1 prevented c-Src recruitment into the endosomal compartment following H/R. Given that Rac1 is a known activator of Nox1 and Nox2, we investigated whether these two proteins were required for c-Src activation in Nox-deficient primary fibroblasts. Findings from these studies suggest that both Nox1 and Nox2 participate in the initial redox activation of c-Src following H/R. In summary, our results suggest that Rac1-dependent Noxs play a

critical role in activating c-Src following H/R injury. This signalling pathway may be a useful therapeutic target for ischaemia/reperfusion-related diseases.

3.1079 Proteomic Analysis of Highly Purified Peroxisomes from Etiolated Soybean Cotyledons
Arai, Y., Hayashi, M. and Nishimura, M.
Plant Cell. Physiol., ***49(4)***, *526-539 (2008)*

To identify previously unknown peroxisomal proteins, we established an optimized method for isolating highly purified peroxisomes from etiolated soybean cotyledons using Percoll density gradient centrifugation followed by **iodixanol** density gradient centrifugation. Proteins in highly purified peroxisomes were separated by two-dimensional PAGE. We performed peptide mass fingerprinting of proteins separated in the gel with matrix-assisted laser desorption ionization time-of-flight mass spectrometry and used the peptide mass fingerprints to search a non-redundant soybean expressed sequence tag database. We succeeded in assigning 92 proteins to 70 sequences in the database. Among them, proteins encoded by 30 sequences were judged to be located in peroxisomes. These included enzymes for fatty acid **β**-oxidation, the glyoxylate cycle, photorespiratory glycolate metabolism, stress response and metabolite transport. We also show experimental evidence that plant peroxisomes contain a short-chain dehydrogenase/reductase family protein, enoyl-CoA hydratase/isomerase family protein, 3-hydroxyacyl-CoA dehydrogenase-like protein and a voltage-dependent anion-selective channel protein.

3.1080 A fluorescent sphingolipid binding domain peptide probe interacts with sphingolipids and cholesterol-dependent raft domains
Hebbar, S. et al
J. Lipid Res., ***49***, *1077-1089 (2008)*

We have designed a tagged probe [sphingolipid binding domain (SBD)] to facilitate the tracking of intracellular movements of sphingolipids in living neuronal cells. SBD is a small peptide consisting of the SBD of the amyloid precursor protein. It can be conjugated to a fluorophore of choice and exogenously applied to cells, thus allowing for in vivo imaging. Here, we present evidence to describe the characteristics of the SBD association with the plasma membrane. Our experiments demonstrate that SBD binds to isolated raft fractions from human neuroblastomas and insect neuronal cells. In protein-lipid overlay experiments, SBD interacts with a subset of glycosphingolipids and sphingomyelin, consistent with its raft association in neurons. We also provide evidence that SBD is taken up by neuronal cells in a cholesterol- and sphingolipid-dependent manner via detergent-resistant microdomains. Furthermore, using fluorescence correlation spectroscopy to assay the mobility of SBD in live cells, we show that SBD's behavior at the plasma membrane is similar to that of the previously described raft marker cholera toxin B, displaying both a fast and a slow component. Our data suggest that fluorescently tagged SBD can be used to investigate the dynamic nature of glycosphingolipid-rich detergent-resistant microdomains that are cholesterol-dependent.

3.1081 CFTR in a lipid raft-TNFR1 complex modulates gap junctional intercellular communication and IL-8 secretion
Dudez, T. et al
Biochim. Biophys. Acta, ***1783***, *779-788 (2008)*

Mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) cause a chronic inflammatory response in the lung of patients with Cystic Fibrosis (CF). We have showed that TNF-∗ signaling through the Src family tyrosine kinases (SFKs) was defective as determined by an inability of TNF-∗ to regulate gap junctional communication (GJIC) in CF cells. Here, we sought to elucidate the mechanisms linking TNF-∗ signaling to the functions of CFTR at the molecular level. In a MDCKI epithelial cell model expressing wild-type (WtCFTR) or mutant CFTR lacking its PDZ-interacting motif (CFTR-ΔTRL), TNF-∗ increased the amount of WtCFTR but not CFTR-ΔTRL in detergent-resistant membrane microdomains (DRMs). This recruitment was modulated by SFK activity and associated with DRM localization of TNFR1 and c-Src. Activation of TNFR1 signaling also decreased GJIC and markedly stimulated IL-8 production in WtCFTR cells. In contrast, the absence of CFTR in DRMs was associated with abnormal TNFR1 signaling as revealed by no recruitment of TNFR1 and c-Src to lipid rafts in CFTR-ΔTRL cells and loss of regulation of GJIC and IL-8 secretion. These results suggest that localization of CFTR in lipid rafts in association with c-Src and TNFR1 provides a responsive signaling complex to regulate GJIC and cytokine signaling.

3.1082 Differential membrane compartmentalization of Ret by PTB-adaptor engagement
Lundgren, T.K., Luebke, M., Stenqvist, A. and Ernfors, P.
*FEBS J., **275**, 2055-2066 (2008)*

Glial cell line-derived neurotrophic factor family ligands act through the receptor tyrosine kinase Ret, which plays important roles during embryonic development for cell differentiation, survival, and migration. Ret signaling is markedly affected by compartmentalization of receptor complexes into membrane subdomains. Ret can propagate biochemical signaling from within concentrates in cholesterol-rich membrane microdomains or lipid rafts, or outside such regions, but the mechanisms for, and consequences of, Ret translocation between these membrane compartments remain largely unclear. Here we investigate the interaction of Shc and Frs2 phosphotyrosine-binding domain-containing adaptor molecules with Ret and their function in redistributing Ret to specialized membrane compartments. We found that engagement of Ret with the Frs2 adaptor results in an enrichment of Ret in lipid rafts and that signal transduction pathways and chemotaxis responses depend on the integrity of such rafts. The competing Shc adaptor did not promote Ret translocation to equivalent domains, and Shc-mediated effects were less affected by disruption of lipid rafts. However, by expressing a chimeric Shc protein that localizes to lipid rafts, we showed that biochemical signaling downstream of Ret resembled that of Ret signaling via Frs2. We have identified a previously unknown mechanism in which phosphotyrosine-binding domain-containing adaptors, by means of relocating Ret receptor complexes to lipid rafts, segregate diverse signaling and cellular functions mediated by Ret. These results reveal the existence of a novel mechanism that could, by subcellular relocation of Ret, work to amplify ligand gradients during chemotaxis.

3.1083 Sequestration of NF-κB Signaling Complexes in Lipid Rafts Contributes to Repression of NF-κB in T Lymphocytes under Hyperthermia Stress
Yan, G., Huang, J., Ruth Jarbadan, N., Jiang, Y. And Cheng, H.
*J. Biol. Chem., **283(18)**, 12489-12500 (2008)*

Sepsis causes extensive apoptosis of lymphocytes, a pathological condition that is frequently associated with hyperthermia. Heat stress has been implicated to repress the activation of an inflammatory mediator, nuclear factor of κB (NF-κB), which sensitizes cells to apoptosis mediated by inflammatory cytokine, tumor necrosis factor α. However, the molecular mechanism of hyperthermia-associated loss of T cells remains unclear. We show that hyperthermia causes rapid translocation of IκB kinase (IKK) and NF-κB complexes into the plasma membrane-associated lipid rafts in T cells. Heat stress induces aggregation of Carma1 in lipid rafts, which in turn recruits protein kinase Cθ (PKCθ) and Bcl10 to the microdomains, causing subsequent membrane translocation of the IKK and NF-κB signalosomes. Depletion of Carma1 and inhibition of PKCθ impair accumulation of NF-κB complexes in lipid rafts. Heat stress prohibits IκB kinase activity by sequestrating the IKK and NF-κB complexes in lipid rafts and by segregating the chaperone protein Hsp90, an essential cofactor for IKK, from the IKK complex. This process ultimately results in functional deficiency of NF-κB and renders T cells resistant to tumor necrosis factor α-induced activation of IKK, thereby contributing to the apoptotic loss of T lymphocytes in sepsis-associated hyperthermia.

3.1084 MALS-3 regulates polarity and early neurogenesis in the developing cerebral cortex
Srinivasan, K. et al
*Development, **135**, 1781-1790 (2008)*

Apicobasal polarity plays an important role in regulating asymmetric cell divisions by neural progenitor cells (NPCs) in invertebrates, but the role of polarity in mammalian NPCs is poorly understood. Here, we characterize the function of the PDZ domain protein MALS-3 in the developing cerebral cortex. We find that MALS-3 is localized to the apical domain of NPCs. Mice lacking all three MALS genes fail to localize the polarity proteins PATJ and PALS1 apically in NPCs, whereas the formation and maintenance of adherens junctions appears normal. In the absence of MALS proteins, early NPCs progressed more slowly through the cell cycle, and their daughter cells were more likely to exit the cell cycle and differentiate into neurons. Interestingly, these effects were transient; NPCs recovered normal cell cycle properties during late neurogenesis. Experiments in which MALS-3 was targeted to the entire membrane resulted in a breakdown of apicobasal polarity, loss of adherens junctions, and a slowing of the cell cycle. Our results suggest that MALS-3 plays a role in maintaining apicobasal polarity and is required for normal neurogenesis in the developing cortex.

3.1085 **Down-regulation of insulin-degrading enzyme by presenilin 1 V97L mutant potentially underlies increased levels of amyloid beta 42**
Qin, W. and Jia, J.
Eur. J. Neurosci., ***27***, *2425-2432 (2008)*

Amyloid beta (Aβ)42 plays a pivotal role in Alzheimer's disease. We previously reported a novel presenilin (PS)1 mutant (V97L) that was expressed in related patients with early onset Alzheimer's disease. We found that patients with the V97L mutation had increased levels of extracellular and intracellular Aβ42. Here we found that the increased extracellular level of Aβ42 was always accompanied by a reduction of insulin-degrading enzyme (IDE) activity on the plasma membranes. However, increase of intracellular Aβ42 was associated with decreased expression and activity of IDE in the cytosol and endoplasmic reticulum in the PS1 V97L mutant-transfected human SH-SY5Y cell line. These studies indicate that pathological levels of Aβ42 may be caused by the negative effects of PS1 (V97L) on IDE expression and activity. Our findings provide evidence for the molecular basis of familial Alzheimer's disease pathogenesis.

3.1086 **Aberrant Folding of Pathogenic Parkin Mutants: AGGREGATION VERSUS DEGRADATION**
Schlehe, J.S. et al
J. Biol. Chem., ***283(20)***, *13771-13779 (2008)*

Loss-of-function mutations in the Parkin gene (*PARK2*) are responsible for the majority of autosomal recessive Parkinson disease. A growing body of evidence indicates that misfolding and aggregation of Parkin is a major mechanism of Parkin inactivation, accounting for the loss-of-function phenotype of various pathogenic Parkin mutants. Remarkably, wild-type Parkin is also prone to misfolding under certain cellular conditions, suggesting a more general role of Parkin in the pathogenesis of Parkinson disease. We now show that misfolding of Parkin can lead to two phenotypes: the formation of detergent-insoluble, aggregated Parkin, or destabilization of *J. Neurochem.*, *105*Parkin resulting in an accelerated proteasomal degradation. By combining two pathogenic Parkin mutations, we could demonstrate that destabilization of Parkin is dominant over the formation of detergent-insoluble Parkin aggregates. Furthermore, a comparative analysis with HHARI, an E3 ubiquitin ligase with an RBR domain highly homologous to that of Parkin, revealed that folding of Parkin is specifically dependent on the integrity of the C-terminal domain, but not on the presence of a putative PDZ-binding motif at the extreme C terminus.

3.1087 **Activated Nuclear Metabotropic Glutamate Receptor mGlu5 Couples to Nuclear Gq/11 Proteins to Generate Inositol 1,4,5-Trisphosphate-mediated Nuclear Ca2+ Release**
Kumar, V., Jong, Y-J.I. and O'Malley, K.L.
J. Biol. Chem., ***283(20)***, *14072-14083 (2008)*

Recently we have shown that the metabotropic glutamate 5 (mGlu5) receptor can be expressed on nuclear membranes of heterologous cells or endogenously on striatal neurons where it can mediate nuclear Ca^{2+} changes. Here, pharmacological, optical, and genetic techniques were used to show that upon activation, nuclear mGlu5 receptors generate nuclear inositol 1,4,5-trisphosphate (IP_3) *in situ*. Specifically, expression of an mGlu5 F767S mutant in HEK293 cells that blocks $G_{q/11}$ coupling or introduction of a dominant negative $G\alpha_q$ construct in striatal neurons prevented nuclear Ca^{2+} changes following receptor activation. These data indicate that nuclear mGlu5 receptors couple to $G_{q/11}$ to mobilize nuclear Ca^{2+}. Nuclear mGlu5-mediated Ca^{2+} responses could also be blocked by the phospholipase C (PLC) inhibitor, U73122 [GenBank] , the phosphatidylinositol (PI) PLC inhibitor 1-*O*-octadecyl-2-*O*-methyl-*sn*-glycero-3-phosphorylcholine (ET-18-OCH_3), or by using small interfering RNA targeted against PLCβ1 demonstrating that PI-PLC is involved. Direct assessment of inositol phosphate production using a PIP2/IP_3 "biosensor" revealed for the first time that IP_3 can be generated in the nucleus following activation of nuclear mGlu5 receptors. Finally, both IP_3 and ryanodine receptor blockers prevented nuclear mGlu5-mediated increases in intranuclear Ca^{2+}. Collectively, this study shows that like plasma membrane receptors, activated nuclear mGlu5 receptors couple to $G_{q/11}$ and PLC to generate IP_3-mediated release of Ca^{2+} from Ca^{2+}-release channels in the nucleus. Thus the nucleus can function as an autonomous organelle independent of signals originating in the cytoplasm, and nuclear mGlu5 receptors play a dynamic role in mobilizing Ca^{2+} in a specific, localized fashion.

3.1088 **Phorbol ester induced trafficking-independent regulation and enhanced phosphorylation of the dopamine transporter associated with membrane rafts and cholesterol**
Foster, J.D., Adkins, S.D., Lever, J.R. and Vaughan, R.A.

J. Neurochem., ***105***, *1683-1699 (2008)*

We examined the mechanisms involved in protein kinase C (PKC)-dependent down-regulation of dopamine transporter (DAT) activity and cell surface expression by treating heterologously expressing cells with the clathrin-mediated endocytosis inhibitor concanavalin A (Con A) or the cholesterol depleter/membrane raft disrupter methyl-β-cyclodextrin (MβC) prior to treatment with the PKC activator phorbol 12-myristate, 13-acetate (PMA). Con A blocked PMA-induced surface reductions of DAT but only partially inhibited down-regulation, while MβC partially blocked down-regulation but did not inhibit loss of cell surface DAT, demonstrating that PKC-induced DAT down-regulation occurs by a combination of trafficking and non-trafficking processes. Using density-gradient centrifugation, we found that DATs are distributed approximately equally between Triton-insoluble, cholesterol-rich membrane rafts and Triton-soluble non-raft membranes. DATs in both populations are present at the cell surface and are active for dopamine and cocaine binding. PMA-induced loss of cell surface DAT occurred only from non-raft populations, demonstrating that non-raft DATs are regulated by trafficking events and indicating the likelihood that the cholesterol-dependent non-trafficking regulatory mechanism occurs in rafts. PMA did not affect the DAT raft-non-raft distribution but stimulated the phosphorylation of DAT to a substantially greater level in rafts than non-rafts. These findings reveal a previously unknown role for cholesterol in DAT function and demonstrate the presence of distinct subcellular DAT populations that possess multiple regulatory differences that may impact dopaminergic neurotransmission.

3.1089 Epstein-Barr Virus Latent Membrane Protein 1 Induces Expression of the Epidermal Growth Factor Receptor through Effects on Bcl-3 and STAT3
Kung,, C-P. and Raab-Traub, N.
J. Virol., ***82(11)***, *5486-5493 (2008)*

Epstein-Barr virus (EBV) latent membrane protein 1 (LMP1) activates multiple signaling pathways. Two regions, C-terminal-activating region 1 (CTAR1) and CTAR2, have been identified within the cytoplasmic carboxy terminal domain that activates NF-κB. CTAR2 activates the canonical NF-κB pathway, which includes p50/p65 complexes. CTAR1 can activate both the canonical and noncanonical pathways to produce multiple distinct NF-κB dimers, including p52/p50, p52/p65, and p50/p50. CTAR1 also uniquely upregulates the epidermal growth factor receptor (EGFR) in epithelial cells. Increased p50-Bcl-3 complexes have been detected by chromatin precipitation on the NF-κB consensus motifs within the *egfr* promoter in CTAR1-expressing epithelial cells and nasopharyngeal carcinoma cells. In this study, the mechanism responsible for the increase in Bcl-3 has been further investigated. The data indicate that LMP1-CTAR1 induces Bcl-3 mRNA and increases the nuclear translocation of both Bcl-3 and p50. LMP1-CTAR1 constitutively activates STAT3, and this activation was not due to the induction of interleukin 6 (IL-6). In LMP1-CTAR1-expressing cells, increased levels of activated STAT3 were detected by chromatin immunoprecipitation on STAT-binding sites located within both the promoter and the second intron of Bcl-3. A STAT3 inhibitor significantly reduced the activation of STAT3, as well as the CTAR1-mediated upregulation of Bcl-3 and EGFR. These data suggest that LMP1 activates distinct forms of NF-κB through multiple pathways. In addition to activating the canonical and noncanonical pathways, LMP1-CTAR1 constitutively activates STAT3 and increases Bcl-3. The increased nuclear Bcl-3 and p50 homodimer complexes positively regulate EGFR expression. These results indicate that LMP1 likely regulates distinct cellular genes by activating specific NF-κB pathways.

3.1090 Involvement of human CD44 during Cryptococcus neoformans infection of brain microvascular endothelial cells
Jong, A. et al
Cellular. Microbiol., ***10(6)***, *1313-1326 (2008)*

Pathogenic yeast *Cryptococcus neoformans* causes devastating cryptococcal meningoencephalitis. Our previous studies demonstrated that *C. neoformans* hyaluronic acid was required for invasion into human brain microvascular endothelial cells (HBMEC), which constitute the blood–brain barrier. In this report, we demonstrate that *C. neoformans* hyaluronic acid interacts with CD44 on HBMEC. Our results suggest that HBMEC CD44 is a primary receptor during *C. neoformans* infection, based on the following observations. First, anti-CD44 neutralizing antibody treatment was able to significantly reduce *C. neoformans* association with HBMEC. Second, *C. neoformans* association was considerably impaired using either CD44-knock-down HBMEC or *C. neoformans* hyaluronic acid-deficient strains. Third, overexpression of CD44 in HBMEC increased their association activity towards *C. neoformans*. Fourth, confocal microscopic images showed that CD44 was enriched at and around the *C. neoformans* association sites. Fifth, upon *C. neoformans* and HBMEC engagement, a subpopulation of CD44 and actin

translocated to the host membrane rafts. Our results highlight the interactions between *C. neoformans* hyaluronic acid and host CD44 and the dynamic results of these interactions, which may represent events during the adhesion and entry of *C. neoformans* at HBMEC membrane rafts.

3.1091 Evidence for a Superoxide Permeability Pathway in Endosomal Membranes
Mumbengegwi, D.R., Li, Q., Li, C., Bear, C.E. and Engelhardt, J.F.
Mol. Cell. Biol., ***28(11)***, *3700-3712 (2008)*

The compartmentalized production of superoxide ($\cdot O_2^-$) by endosomal NADPH oxidase is important in the redox-dependent activation of NF-κB following interleukin 1β (IL-1β) stimulation. It remains unclear how $\cdot O_2^-$ produced within endosomes facilitates redox-dependent signaling events in the cytoplasm. We evaluated $\cdot O_2^-$ movement out of IL-1β-stimulated endosomes and whether SOD1 at the endosomal surface mediates redox-signaling events required for NF-κB activation. The relative outward permeability of NADPH-dependent $\cdot O_2^-$ from fractionated endosomes was assessed using membrane-permeable (luminol and lucigenin) and -impermeable (isoluminol) luminescent probes for $\cdot O_2^-$. In these studies, ~60% of $\cdot O_2^-$ efflux out of endosomes was inhibited by treatment with either of two anion channel blockers, 4'-diisothiocyano-2,2'-disulfonic acid stilbene (DIDS) or niflumic acid (NFA). Furthermore, radioisotopic electrodiffusion flux assays on endomembrane proteoliposomes suggested that $\cdot O_2^-$ and Cl^- are transported through the same DIDS-sensitive channel(s). Rab5-based immunoaffinity isolation of IL-1β-stimulated early endosomes demonstrated SOD1 recruitment to endosomes harboring the IL-1 receptor. Finally, SOD1-deficient cells were found to be defective in their ability to activate NF-κB following IL-1β stimulation. Together, these results suggest that $\cdot O_2^-$ exits endosomes through a DIDS-sensitive chloride channel(s) and that SOD1-mediated dismutation of $\cdot O_2^-$ at the endosomal surface may produce the localized H_2O_2 required for redox-activation of NF-κB.

3.1092 Targeting of Pseudorabies Virus Structural Proteins to Axons Requires Association of the Viral Us9 Protein with Lipid Rafts
Lyman, M.G., Curanovic, D. And Enquist, L.W.
PlosPathogens, ***4(5)***, *e1000065*

The pseudorabies virus (PRV) Us9 protein plays a central role in targeting viral capsids and glycoproteins to axons of dissociated sympathetic neurons. As a result, Us9 null mutants are defective in anterograde transmission of infection *in vivo*. However, it is unclear how Us9 promotes axonal sorting of so many viral proteins. It is known that the glycoproteins gB, gC, gD and gE are associated with lipid raft microdomains on the surface of infected swine kidney cells and monocytes, and are directed into the axon in a Us9-dependent manner. In this report, we determined that Us9 is associated with lipid rafts, and that this association is critical to Us9-mediated sorting of viral structural proteins. We used infected non-polarized and polarized PC12 cells, a rat pheochromocytoma cell line that acquires many of the characteristics of sympathetic neurons in the presence of nerve growth factor (NGF). In these cells, Us9 is highly enriched in detergent-resistant membranes (DRMs). Moreover, reducing the affinity of Us9 for lipid rafts inhibited anterograde transmission of infection from sympathetic neurons to epithelial cells *in vitro*. We conclude that association of Us9 with lipid rafts is key for efficient targeting of structural proteins to axons and, as a consequence, for directional spread of PRV from pre-synaptic to post-synaptic neurons and cells of the mammalian nervous system.

3.1093 Cholesterol Substitution Increases the Structural Heterogeneity of Caveolae
Jansen, M. et al
J. Biol. Chem., ***283(21)***, *14610-14618 (2008)*

Caveolin-1 binds cholesterol and caveola formation involves caveolin-1 oligomerization and cholesterol association. The role of cholesterol in caveolae has so far been addressed by methods that compromise membrane integrity and abolish caveolar invaginations. To study the importance of sterol specificity for the structure and function of caveolae, we replaced cholesterol in mammalian cells with its immediate precursor desmosterol by inhibiting 24-dehydrocholesterol reductase. Desmosterol could substitute for cholesterol in maintaining cell growth, membrane integrity, and preserving caveolar invaginations. However, in desmosterol cells the affinity of caveolin-1 for sterol and the stability of caveolin oligomers were decreased. Moreover, caveolar invaginations became more heterogeneous in dimensions and in the number of caveolin-1 molecules per caveola. Despite the altered caveolar structure, caveolar ligand uptake was only moderately inhibited. We found that in desmosterol cells, Src kinase phosphorylated Cav1 at Tyr^{14} more avidly than in cholesterol cells. Taken the role of Cav1 Tyr^{14} phosphorylation in caveolar

endocytosis, this may help to preserve caveolar uptake in desmosterol cells. We conclude that a sterol C24 double bond interferes with caveolin-sterol interaction and perturbs caveolar morphology but facilitates Cav1 Src phosphorylation and allows caveolar endocytosis. More generally, substitution of cholesterol by a structurally closely related sterol provides a method to selectively modify membrane protein-sterol affinity, structure and function of cholesterol-dependent domains without compromising membrane integrity.

3.1094 Synaptic Vesicles Are Constitutively Active Fusion Machines that Function Independently of Ca^{2+}
Holt, M., Riedel, D., Stein, A., Schuette, C. and Jahn, R.
*Current Biology, **18**, 715-722 (2008)*

Background
In neurons, release of neurotransmitter occurs through the fusion of synaptic vesicles with the plasma membrane. Many proteins required for this process have been identified, with the SNAREs syntaxin 1, SNAP-25, and synaptobrevin thought to constitute the core fusion machinery. However, there is still a large gap between our understanding of individual protein-protein interactions and the functions of these proteins revealed by perturbations in intact synaptic preparations. To bridge this gap, we have used purified synaptic vesicles, together with artificial membranes containing coreconstituted SNAREs as reaction partners, in fusion assays.
Results
By using complementary experimental approaches, we show that synaptic vesicles fuse constitutively, and with high efficiency, with proteoliposomes containing the plasma membrane proteins syntaxin 1 and SNAP-25. Fusion is inhibited by clostridial neurotoxins and involves the formation of SNARE complexes. Despite the presence of endogenous synaptotagmin, Ca^{2+} does not enhance fusion, even if phosphatidylinositol 4,5-bisphosphate is present in the liposome membrane. Rather, fusion kinetics are dominated by the availability of free syntaxin 1/SNAP-25 acceptor sites for synaptobrevin.
Conclusions
Synaptic vesicles are constitutively active fusion machines, needing only synaptobrevin for activity. Apparently, the final step in fusion does not involve the regulatory activities of other vesicle constituents, although these may be involved in regulating earlier processes. This is particularly relevant for the calcium-dependent regulation of exocytosis, which, in addition to synaptotagmin, requires other factors not present in the vesicle membrane. The in vitro system described here provides an ideal starting point for unraveling of the molecular details of such regulatory events.

3.1095 Caveolae structure and function
Thomas, C.M. and Smart, E.J.
*J. Cell. Mol. Med., **12(3)**, 796-809 (2008)*

Studies on the structure and function of caveolae have revealed how this versatile subcellular organelle can influence numerous signalling pathways. This brief review will discuss a few of the key features of caveolae as it relates to signalling and disease processes.

3.1096 Segregation and rapid turnover of EDEM1 by an autophagy-like mechanism modulates standard ERAD and folding activities
Cali, T., Galli, C., Olivari, S. And Molinari, M.
*Biochem. Biophys. Res. Comm., **371**, 405-410 (2008)*

EDEM1 is a crucial regulator of endoplasmic reticulum (ER)-associated degradation (ERAD) that extracts non-native glycopolypeptides from the calnexin chaperone system. Under normal growth conditions, the intralumenal level of EDEM1 must be low to prevent premature interruption of ongoing folding programs. We report that in unstressed cells, EDEM1 is segregated from the bulk ER into LC3-I-coated vesicles and is rapidly degraded. The rapid turnover of EDEM1 is regulated by a novel mechanism that shows similarities but is clearly distinct from macroautophagy. Cells with defective EDEM1 turnover contain unphysiologically high levels of EDEM1, show enhanced ERAD activity and are characterized by impaired capacity to efficiently complete maturation of model glycopolypeptides. We define as *ERAD tuning* the mechanisms operating in the mammalian ER at steady state to offer kinetic advantage to folding over disposal of unstructured nascent chains by selective and rapid degradation of ERAD regulators.

3.1097 Caveolin-1 Expression in Trabecular Meshwork Cells
Nolan, M.J. et al
*Invest. Ophthalmol. Vis. Sci., **49**, E-abstract 1627 (2008)*

Purpose: Caveolin-1, a 22-kDa, intergral membrane protein forming oligomers in cells, is a principal component of caveolae in lipid rafts and is also important in regulating vesicle trafficking through cells. Caveolin-1 is involved, consequently, in signal transduction, tight junction formation, endocytosis, transcytosis, as well serving as a mechanosensor in endothelial cells. Lipid-modified proteins such as endothelial nitric oxide synthase and the Src family of kinases can target to caveolae and interact with caveolin-1 to regulate signal transduction. The purpose of this study was to determine whether trabecular meshwork (TM) cells express caveolin-1 and if caveolin-1 expression is influenced by dexamethasone (Dex) treatment.
Methods: Human TM cells were grown in Dulbecco's Modified Eagle's Medium (DMEM) containing 10% fetal calf serum (FCS) until confluent, washed twice with PBS, and incubated in DMEM containing 0.1% FCS and 100 µM Dex for 1, 24 and 96 hours. The media was aspirated; the cells were washed with cold PBS, subjected to lysis buffer (Sigma CS0750) containing 1% Triton X-100, and separated by **Optiprep** density gradient (Sigma D1556). The preparation was centrifuged at 200,000 x g for 18 hrs; nine 0.5 ml fractions were pipetted from the top (lightest) to bottom (heaviest). Each fraction was analyzed for protein content, resolved by SDS polyarylamide electrophoresis, and immunoblotted with mouse monoclonal anti-caveolin-1 antibody (Sigma).
Results: The distribution of 22-kDa caveolin-1 in TM cells was in fractions 4 through 7 and the strongest intensity was in fraction 5; a high molecular weight (>300-kDa) was observed in fractions 5 through 7. The distribution of 22-kDa caveolin-1 in Dex-treated TM cells was in fractions 5 through 7 and the strongest intensity was in fractions 5 and 6, with minor amounts in fraction 8 and 9; a high molecular weight (>300-kDa) was also observed in fractions 5 through 7. The amount of caveolin-1 in Dex-treated TM cells was considerably greater, approximately two-fold. Similarly, the amount of caveolin-1 in the media was also increased in the Dex-treated TM cells.
Conclusions: This is the first demonstration of caveolin-1 in TM cells. Dex treatment increased the cell caveolin-1 content and changed caveolin-1 density gradient distribution as well as increasing the secretion of media caveolin-1. These results indicate that caveolin-1 may play an important role in TM barrier function, cell signaling, and endocytosis.

3.1098 Overexpression of a host factor TOM1 inhibits tomato mosaic virus propagation and suppression of RNA silencing
Hagiwara-Komoda, Y. et al
*Virology, **376**, 132-139 (2008)*

A plant integral membrane protein TOM1 is involved in the multiplication of *Tomato mosaic virus* (ToMV). TOM1 interacts with ToMV replication proteins and has been suggested to tether the replication proteins to the membranes where the viral RNA synthesis takes place. We have previously demonstrated that inactivation of *TOM1* results in reduced ToMV multiplication. In the present study, we show that overexpression of TOM1 in tobacco also inhibits ToMV propagation. TOM1 overexpression led to a decreased accumulation of the soluble form of the replication proteins and interfered with the ability of the replication protein to suppress RNA silencing. The reduced accumulation of the soluble replication proteins was also observed in a silencing suppressor-defective ToMV mutant. Based on these results, we propose that RNA silencing suppression is executed by the soluble form of the replication proteins and that efficient ToMV multiplication requires balanced accumulation of the soluble and membrane-bound replication proteins.

3.1099 The human SIRT3 protein deacetylase is exclusively mitochondrial
Cooper, H.M: and Spelbrink, J.N.
*Biochem. J., **411**, 279-285 (2008)*

It has recently been suggested that perhaps as many as 20% of all mitochondrial proteins are regulated through lysine acetylation while SIRT3 has been implicated as an important mitochondrial protein deacetylase. It is therefore of crucial importance that the mitochondrial localization of potential protein deacetylases is unambiguously established. Although mouse SIRT3 was recently shown to be mitochondrial, HsSIRT3 (human SIRT3) was reported to be both nuclear and mitochondrial and to relocate from the nucleus to the mitochondrion upon cellular stress. In the present study we show, using various HsSIRT3 expression constructs and a combination of immunofluorescence and careful subcellular

fractionation, that in contrast with earlier reports HsSIRT3 is exclusively mitochondrial. We discuss possible experimental explanations for these discrepancies. In addition we suggest, on the basis of the analysis of public genome databases, that the full-length mouse SIRT3 protein is a 37 kDa mitochondrial precursor protein contrary to the previously suggested 29 kDa protein.

3.1100 CLN3p Impacts Galactosylceramide Transport, Raft Morphology, and Lipid Content
Rusyn, E., Mousallem, T., Persaud-Sawin, D-A., Miller, S. and Boustany, R-M.N.
*Pediatr. Res., **63(6)**, 625-631 (2008)*

Juvenile neuronal ceroid lipofuscinosis (JNCL) belongs to the neuronal ceroid lipofuscinoses characterized by blindness/seizures/motor/cognitive decline and early death. JNCL is caused by CLN3 gene mutations that negatively modulate cell growth/apoptosis. CLN3 protein (CLN3p) localizes to Golgi/Rab4-/Rab11-positive endosomes and lipid rafts, and harbors a galactosylceramide (GalCer) lipid raft-binding domain. Goals are proving CLN3p participates in GalCer transport from Golgi to rafts, and GalCer deficits negatively affect cell growth/apoptosis. GalCer/mutant CLN3p are retained in Golgi, with CLN3p rescuing GalCer deficits in rafts. Diminishing GalCer in normal cells by GalCer synthase siRNA negatively affects cell growth/apoptosis. GalCer restores JNCL cell growth. WT CLN3p binds GalCer, but not mutant CLN3p. Sphingolipid content of rafts/Golgi is perturbed with diminished GalCer in rafts and accumulation in Golgi. CLN3-deficient raft vesicular structures are small by transmission electron microscopy, reflecting altered sphingolipid composition of rafts. CLN1/CLN2/CLN6 proteins bind to lysophosphatidic acid/sulfatide, CLN6/CLN8 proteins to GalCer, and CLN8 protein to ceramide. Sphingolipid composition/morphology of CLN1-/CLN2-/CLN6-/CLN8- and CLN9-deficient rafts are altered suggesting changes in raft structure/lipid stoichiometry could be common themes underlying these diseases.

3.1101 Lovastatin inhibits amyloid precursor protein (APP) [beta]-cleavage through reduction of APP distribution in Lubrol WX extractable low density lipid rafts
Won, J-S. et al
*J. Neurochem., **105**, 1536-1549 (2008)*

Previous studies have described that statins (inhibitors of cholesterol and isoprenoid biosynthesis) inhibit the output of amyloid-[beta] (A[beta]) in the animal model and thus decrease risk of Alzheimer's disease. However, their action mechanism(s) in A[beta] precursor protein (APP) processing and A[beta] generation is not fully understood. In this study, we report that lovastatin treatment reduced A[beta] output in cultured hippocampal neurons as a result of reduced APP levels and [beta]-secretase activities in low density Lubrol WX (non-ionic detergent) extractable lipid rafts (LDLR). Rather than altering cholesterol levels in lipid raft fractions and thus disrupting lipid raft structure, lovastatin decreased A[beta] generation through down-regulating geranylgeranyl-pyrophosphate dependent endocytosis pathway. The inhibition of APP endocytosis by treatment with lovastatin and reduction of APP levels in LDLR fractions by treatment with phenylarsine oxide (a general endocytosis inhibitor) support the involvement of APP endocytosis in APP distribution in LDLR fractions and subsequent APP [beta]-cleavage. Moreover, lovastatin-mediated down-regulation of endocytosis regulators, such as early endosomal antigen 1, dynamin-1, and phosphatidylinositol 3-kinase activity, indicates that lovastatin modulates APP endocytosis possibly through its pleiotropic effects on endocytic regulators. Collectively, these data report that lovastatin mediates inhibition of LDLR distribution and [beta]-cleavage of APP in a geranylgeranyl-pyrophosphate and endocytosis-dependent manner.

3.1102 Synaptotagmin VII Regulates Bone Remodeling by Modulating Osteoclast and Osteoblast Secretion
Zhao, H. et al
*Developmental Cell, **14**, 914-925 (2008)*

Maintenance of bone mass and integrity requires a tight balance between resorption by osteoclasts and formation by osteoblasts. Exocytosis of functional proteins is a prerequisite for the activity of both cells. In the present study, we show that synaptotagmin VII, a calcium sensor protein that regulates exocytosis, is associated with lysosomes in osteoclasts and bone matrix protein-containing vesicles in osteoblasts. Absence of synaptotagmin VII inhibits cathepsin K secretion and formation of the ruffled border in osteoclasts and bone matrix protein deposition in osteoblasts, without affecting the differentiation of either cell. Reflecting these in vitro findings, synaptotagmin VII-deficient mice are osteopenic due to impaired bone resorption and formation. Therefore, synaptotagmin VII plays an important role in bone remodeling and homeostasis by modulating secretory pathways functionally important in osteoclasts and osteoblasts.

3.1103 Multimerization of Tegument Protein pp28 within the Assembly Compartment Is Required for Cytoplasmic Envelopment of Human Cytomegalovirus
Seo, J-Y. and Britt, W.J.
*J. Virol., **82(13)**, 6272-7287 (2008)*

Human cytomegalovirus (HCMV) UL99-encoded pp28 is an essential tegument protein required for envelopment and production of infectious virus. Nonenveloped virions accumulate in the cytoplasm of cells infected with recombinant viruses with the UL99 gene deleted. Previous results have suggested that a key function of pp28 in the envelopment of infectious HCMV is expressed after the protein localizes in the assembly compartment (AC). In this study, we investigated the potential role of pp28 multimerization in the envelopment of the infectious virion. Our results indicated that pp28 multimerized during viral infection and that interacting domains responsible for self-interaction were localized in the amino terminus of the protein (amino acids [aa] 1 to 43). The results from transient-expression and/or infection assays indicated that the self-interaction took place in the AC. A mutant pp28 molecule containing only the first 35 aa failed to accumulate in the AC, did not interact with pp28 in the AC, and could not support virus replication. In contrast, the first 50 aa of pp28 was sufficient for the self-interaction within the AC and the assembly of infectious virus. Recombinant viruses encoding an in-frame deletion of aa 26 to 33 of pp28 were replication competent, whereas infectious virus was not recovered from HCMV BACs lacking aa 26 to 43. These findings suggested that the accumulation of pp28 was a prerequisite for multimerization of pp28 within the AC and that pp28 multimerization in the AC represented an essential step in the envelopment and production of infectious virions.

3.1104 Functional stabilization of Kv1.5 protein by Hsp70 in mammalian cell lines
Hirota, Y. et al
*Biochem. Biophys. Acta., **372**, 469-474 (2008)*

The aim of this study was to elucidate the mechanisms for regulations of cardiac Kv1.5 channel expression. We particularly focused on the role of heat shock proteins (Hsps). We tested the effects of Hsps on the stability of Kv1.5 channels using biochemical and electrophysiological techniques: co-expression of Kv1.5 and Hsp family proteins in mammalian cell lines, followed by Western blotting, immunoprecipitation, pulse-chase analysis, immunofluorescence and whole-cell patch clamp. Hsp70 and heat shock factor 1 increased the expression of Kv1.5 protein in HeLa and COS7 cells, whereas either Hsp40, 27 or 90 did not. Hsp70 prolonged the half-life of Kv1.5 protein. Hsp70 was co-immunoprecipitated and co-localized with Kv1.5-FLAG. Hsp70 significantly increased the immunoreactivity of Kv1.5 in the endoplasmic reticulum, Golgi apparatus and on the cell membrane. Hsp70 enhanced Kv1.5 current of transfected cells, which was abolished by pretreatment with brefeldin A or colchicine. Thus, Hsp70, but not other Hsps, stabilizes functional Kv1.5 protein.

3.1105 Sphingomyelin Functions as a Novel Receptor for Helicobacter pylori VacA
Gupta, V.R. et al
*PLOSpathogens, **4(5)**, e1000073 (2008)*

The vacuolating cytotoxin (VacA) of the gastric pathogen *Helicobacter pylori* binds and enters epithelial cells, ultimately resulting in cellular vacuolation. Several host factors have been reported to be important for VacA function, but none of these have been demonstrated to be essential for toxin binding to the plasma membrane. Thus, the identity of cell surface receptors critical for both toxin binding and function has remained elusive. Here, we identify VacA as the first bacterial virulence factor that exploits the important plasma membrane sphingolipid, sphingomyelin (SM), as a cellular receptor. Depletion of plasma membrane SM with sphingomyelinase inhibited VacA-mediated vacuolation and significantly reduced the sensitivity of HeLa cells, as well as several other cell lines, to VacA. Further analysis revealed that SM is critical for VacA interactions with the plasma membrane. Restoring plasma membrane SM in cells previously depleted of SM was sufficient to rescue both toxin vacuolation activity and plasma membrane binding. VacA association with detergent-resistant membranes was inhibited in cells pretreated with SMase C, indicating the importance of SM for VacA association with lipid raft microdomains. Finally, VacA bound to SM in an *in vitro* ELISA assay in a manner competitively inhibited by lysenin, a known SM-binding protein. Our results suggest a model where VacA may exploit the capacity of SM to preferentially partition into lipid rafts in order to access the raft-associated cellular machinery previously shown to be required for toxin entry into host cells.

3.1106 Mammalian cell expression of an active site mutant of Pseudomonas exotoxin disrupts LRP1 maturation

Pastrana, D.V., Yun, C.H., McKee, M.L. and FitzGerald, D.J.
J. Biomed. Sci., ***15***, *427-439 (2008)*

Low density lipoprotein receptor-related protein 1, (LRP1) is a large multifunctional receptor that binds more than 25 physiologic ligands. In addition, it functions as the surface receptor for several Rhinoviruses, HIV-tat and Pseudomonas exotoxin (PE). We report that the expression of PE within mammalian cells can serve as a probe of LRP1 maturation and functionality. To avoid cell killing, an enzymatically inactive form of the toxin (PEΔ553) was expressed. A permanent cell line (termed CY301) was established whereby PEΔ553 was expressed continually into the ER of CHO cells. CY301 cells were 100-fold resistant to exogenously added active PE but exhibited no cross-resistance to other toxins. Our studies indicate that PEΔ553 bound to immature LRP1 in the ER, prevented its maturation to the cell surface and thereby produced a toxin resistant phenotype. By confocal microscopy, cell-associated PEΔ553 was localized to the ER and co-localized with LRP1. Further characterization of CY301 cells indicated that RAP, the chaperone that aids in LRP1 folding, was released to the growth media. Thus the intracellular expression of PEΔ553 appears to be a valuable probe of LRP1 maturation and trafficking.

3.1107 Engineered Bacterial Outer Membrane Vesicles with Enhanced Functionality

Kim, J-Y. et al
J. Mol. Biol., ***380***, *51-66 (2008)*

We have engineered bacterial outer membrane vesicles (OMVs) with dramatically enhanced functionality by fusing several heterologous proteins to the vesicle-associated toxin ClyA of *Escherichia coli*. Similar to native unfused ClyA, chimeric ClyA fusion proteins were found localized in bacterial OMVs and retained activity of the fusion partners, demonstrating for the first time that ClyA can be used to co-localize fully functional heterologous proteins directly in bacterial OMVs. For instance, fusions of ClyA to the enzymes β-lactamase and organophosphorus hydrolase resulted in synthetic OMVs that were capable of hydrolyzing β-lactam antibiotics and paraoxon, respectively. Similarly, expression of an anti-digoxin single-chain Fv antibody fragment fused to the C terminus of ClyA resulted in designer “immuno-MVs” that could bind tightly and specifically to the antibody's cognate antigen. Finally, OMVs displaying green fluorescent protein fused to the C terminus of ClyA were highly fluorescent and, as a result of this new functionality, could be easily tracked during vesicle interaction with human epithelial cells. We expect that the relative plasticity exhibited by ClyA as a fusion partner should prove useful for: (i) further mechanistic studies to identify the vesiculation machinery that regulates OMV secretion and to map the intracellular routing of ClyA-containing OMVs during invasion of host cells; and (ii) biotechnology applications such as surface display of proteins and delivery of biologics.

3.1108 Cholesterol Depletion Reduces Helicobacter pylori CagA Translocation and CagA-Induced Responses in AGS Cells

Lai, C-H. et al
Infect. Immun., ***76(7)***, *3293-3303 (2008)*

Infection with *Helicobacter pylori cagA*-positive strains is associated with gastritis, ulcerations, and gastric cancer. CagA is translocated into infected epithelial cells by a type IV secretion system and can be tyrosine phosphorylated, inducing signal transduction and motogenic responses in epithelial cells. Cellular cholesterol, a vital component of the membrane, contributes to membrane dynamics and functions and is important in VacA intoxication and phagocyte evasion during *H. pylori* infection. In this investigation, we showed that cholesterol extraction by methyl-β-cyclodextrin reduced the level of CagA translocation and phosphorylation. Confocal microscope visualization revealed that a significant portion of translocated CagA was colocalized with the raft marker GM1 and c-Src during infection. Moreover, GM1 was rapidly recruited into sites of bacterial attachment by live-cell imaging analysis. CagA and VacA were cofractionated with detergent-resistant membranes (DRMs), suggesting that the distribution of CagA and VacA is associated with rafts in infected cells. Upon cholesterol depletion, the distribution shifted to non-DRMs. Accordingly, the CagA-induced hummingbird phenotype and interleukin-8 induction were blocked by cholesterol depletion. Raft-disrupting agents did not influence bacterial adherence but did significantly reduce internalization activity in AGS cells. Together, these results suggest that delivery of CagA into epithelial cells by the bacterial type IV secretion system is mediated in a cholesterol-dependent manner.

3.1109 Rhesus lymphocryptovirus latent membrane protein 2A activates β-catenin signaling and inhibits differentiation in epithelial cells
Siler, C.A. and Raab-Traub, N.
*Virology, **377**, 273-279 (2008)*

Rhesus lymphocryptovirus (LCV) is a γ-herpesvirus closely related to Epstein–Barr virus (EBV). The rhesus latent membrane protein 2A (LMP2A) is highly homologous to EBV LMP2A. EBV LMP2A activates the phosphatidylinositol 3-kinase (PI3K) and β-catenin signaling pathways in epithelial cells and affects differentiation. In the present study, the biochemical and biological properties of rhesus LMP2A in epithelial cells were investigated. The expression of rhesus LMP2A in epithelial cells induced Akt activation, GSK3β inactivation and accumulation of β-catenin in the cytoplasm and nucleus. The nuclear translocation, but not accumulation of β-catenin was dependent on Akt activation. Rhesus LMP2A also impaired epithelial cell differentiation; however, this process was not dependent upon Akt activation. A mutant rhesus LMP2A lacking six transmembrane domains functioned similarly to wild-type rhesus LMP2A indicating that the full number of transmembrane domains is not required for effects on β-catenin or cell differentiation. These results underscore the similarity of LCV to EBV and the suitability of the macaque as an animal model for studying EBV pathogenesis.

3.1110 Canine MDCK cell lines are refractory to infection with human and mouse prions
Polymenidou, M. et al
*Vaccine, **26**, 2601-2614 (2008)*

Influenza vaccine production in embryonated eggs is associated with many disadvantages, and production in cell culture systems is a viable alternative. Madin Darby canine kidney (MDCK) cells are permissive for a variety of orthomyxoviruses and have proven particularly suitable for vaccine mass production. However, mammalian cells harboring the *Prnp* gene can theoretically acquire prion infections. Here, we have attempted to infect MDCK cells and substrains thereof with prions. We found that MDCK cells did not produce any protease-resistant PrP^{Sc} upon exposure to brain homogenates derived from humans suffering from Creutzfeldt–Jakob disease (CJD) or from mice infected with Rocky Mountain Laboratory (RML) scrapie prions. Further, transmission of MDCK lysates to N2aPK1 cells did not induce formation of PrP^{Sc} in the latter. PrP^{C} biogenesis and processing in MDCK cells were similar to those of prion-sensitive N2aPK1 cells. However, steady-state levels of PrP^{C} were very low, and PrP^{C} did not partition with detergent-resistant membranes upon density gradient analysis. These factors may account for their resistance to infection. Alternatively, prion resistance may be related to the specific sequence of canine *Prnp*, as suggested by the lack of documented prion diseases in dogs.

3.1111 Differential loss of cytochrome-c oxidase subunits in ischemia-reperfusion injury: exacerbation of COI subunit loss by PKC-ε inhibition
Yu, Q., Nguyen, T., Ogbi, M., Caldqwell, R.W. and Johnson, J.A.
*Am. J. Physiol. Heart Circ. Physiol., **294**, H2637-H2645 (2008)*

We have previously described a PKC-ε interaction with cytochrome oxidase subunit IV (COIV) that correlates with enhanced CO activity and cardiac ischemic preconditioning (PC). We therefore investigated the effects of PC and ischemia-reperfusion (I/R) injury on CO subunit levels in an anesthetized rat coronary ligation model. Homogenates prepared from the left ventricular regions at risk (RAR) and not at risk (RNAR) for I/R injury were fractionated into cell-soluble (S), 600 *g* low-speed centrifugation (L), gradient-purified mitochondrial (M), and 100,000 *g* particulate (P) fractions. In RAR tissue, PC (2 cycles of 5-min ischemia and 5-min reperfusion) decreased the COI in the P fraction (~29% of total cellular COI), suggesting changes in interfibrillar mitochondria. After 30 min of ischemia and 120 min of reperfusion, total COI levels decreased in the RAR by 72%. Subunit Va was also downregulated by 42% following prolonged I/R in the RAR. PC administered before I/R reduced the loss of COI in the M and P fractions ~30% and prevented COVa losses completely. We observed no losses in subunits Vb and VIIa following I/R alone; however, significant losses occurred when PC was administered before prolonged I/R. Delivery of a cell-permeable PKC-ε translocation inhibitor (εV1-2) to isolated rat hearts before prolonged I/R dramatically increased COI loss, suggesting that PKC-ε protects COI levels. We propose that additional measures to protect CO subunits when coadministered with PC may improve its cardioprotection against I/R injury.

3.1112 CD20 Homo-oligomers Physically Associate with the B Cell Antigen Receptor: DISSOCIATION UPON RECEPTOR ENGAGEMENT AND RECRUITMENT OF PHOSPHOPROTEINS AND CALMODULIN-BINDING PROTEINS

Polyak, M.J., Li, H., Shariat, N. And Deans, J.P.
J. Biol. Chem., ***283(27)***, *18545-18552 (2008)*

B cell antigen receptor (BCR) signaling initiates sustained cellular calcium influx necessary for the development, differentiation, and activation of B lymphocytes. CD20 is a B cell-restricted tetraspanning protein organized in the plasma membrane as multimeric molecular complexes involved in BCR-activated calcium entry. Using coprecipitation of native CD20 with tagged or truncated forms of the molecule, we provide here direct evidence of CD20 homo-oligomerization into tetramers. Additionally, the function of CD20 was explored by examining its association with surface-labeled and intracellular proteins before and after BCR signaling. Two major surface-labeled proteins that coprecipitated with CD20 were identified as the heavy and light chains of cell surface IgM, the antigen-binding components of the BCR. After activation, BCR-CD20 complexes dissociated, and phosphoproteins and calmodulin-binding proteins were transiently recruited to CD20. These data provide new evidence of the involvement of CD20 in signaling downstream of the BCR and, together with the previously described involvement of CD20 in calcium influx, the first evidence of physical coupling of the BCR to a calcium entry pathway.

3.1113 The Subcellular Distribution of Calnexin Is Mediated by PACS-2

Myhill, N. et aql
Mol. Cell Biol., ***19***, *2777-2788 (2008)*

Calnexin is an endoplasmic reticulum (ER) lectin that mediates protein folding on the rough ER. Calnexin also interacts with ER calcium pumps that localize to the mitochondria-associated membrane (MAM). Depending on ER homeostasis, varying amounts of calnexin target to the plasma membrane. However, no regulated sorting mechanism is so far known for calnexin. Our results now describe how the interaction of calnexin with the cytosolic sorting protein PACS-2 distributes calnexin between the rough ER, the MAM, and the plasma membrane. Under control conditions, more than 80% of calnexin localizes to the ER, with the majority on the MAM. PACS-2 knockdown disrupts the calnexin distribution within the ER and increases its levels on the cell surface. Phosphorylation by protein kinase CK2 of two calnexin cytosolic serines (Ser554/564) reduces calnexin binding to PACS-2. Consistent with this, a Ser554/564 ⟶ Asp phosphomimic mutation partially reproduces PACS-2 knockdown by increasing the calnexin signal on the cell surface and reducing it on the MAM. PACS-2 knockdown does not reduce retention of other ER markers. Therefore, our results suggest that the phosphorylation state of the calnexin cytosolic domain and its interaction with PACS-2 sort this chaperone between domains of the ER and the plasma membrane.

3.1114 Triglyceride-rich lipoprotein lipolysis increases aggregation of endothelial cell membrane microdomains and produces reactive oxygen species

Wang, L., Sapuri-Butti, A.R., Aung, H.H., Parikh, A.N. and Rutlegde, J.C.
Am. J. Physiol. Heart Circ. Physiol., ***295***, *H237-H244 (2008)*

Triglyceride-rich lipoprotein (TGRL) lipolysis may provide a proinflammatory stimulus to endothelium. Detergent-resistant plasma membrane microdomains (lipid rafts) have a number of functions in endothelial cell inflammation. The mechanisms of TGRL lipolysis-induced endothelial cell injury were investigated by examining endothelial cell lipid rafts and production of reactive oxygen species (ROS). Lipid raft microdomains in human aortic endothelial cells were visualized by confocal microscopy with fluorescein isothiocyanate-labeled cholera toxin B as a lipid raft marker. Incubation of Atto565-labeled TGRL with lipid raft-labeled endothelial cells showed that TGRL colocalized with the lipid rafts, TGRL lipolysis caused clustering and aggregation of lipid rafts, and colocalization of TGRL remnant particles on the endothelial cells aggregated lipid rafts. Furthermore, TGRL lipolysis caused translocation of low-density lipoprotein receptor-related protein, endothelial nitric oxide synthase, and caveolin-1 from raft regions to nonraft regions of the membrane 3 h after treatment with TGRL lipolysis. TGRL lipolysis significantly increased the production of ROS in endothelial cells, and both NADPH oxidase and cytochrome *P*-450 inhibitors reduced production of ROS. Our studies suggest that alteration of lipid raft morphology and composition and ROS production could contribute to TGRL lipolysis-mediated endothelial cell injury.

3.1115 Characterization of seipin/BSCL2, a protein associated with spastic paraplegia 17

Ito, D., Fujisawa, T., Iida, H and Suzuki, N.
Neurobiol. Disease, ***31(2)***, *266-277 (2008)*

Seipin, which is encoded by the *BSCL2* gene, is a glycoprotein of unknown biochemical function that is associated with dominant hereditary motor neuron diseases. Mutations in the *N*-glycosylation site of seipin are associated with the disease states and result in accumulation of unfolded protein in the endoplasmic reticulum (ER), leading to the unfolded protein response (UPR) and cell death, suggesting that these diseases are tightly associated with ER stress. Here, we determined the subcellular localization, functional domains, and distribution of seipin in tissues. Our studies show that the transmembrane domains in seipin are critical for ER retention, ubiquitination, formation of inclusions, and activation of UPR. Using immunohistochemistry, seipin expression is detected in neurons in the spinal cord and in the frontal lobe cortex of the brain. The present study provides new insights into the biology of seipin protein that should help our understanding of the pathogenesis of seipin-related diseases.

3.1116 EGF induces coalescence of different lipid rafts
Hofman, E.G. et al
*J. Cell Sci., **121**, 2519-2528 (2008)*

The suggestion that microdomains may function as signaling platforms arose from the presence of growth factor receptors, such as the EGFR, in biochemically isolated lipid raft fractions. To investigate the role of EGFR activation in the organization of lipid rafts we have performed FLIM analyses using putative lipid raft markers such as ganglioside GM1 and glycosylphosphatidylinositol (GPI)-anchored GFP (GPI-GFP). The EGFR was labeled using single domain antibodies from *Llama glama* that specifically bind the EGFR without stimulating its kinase activity. Our FLIM analyses demonstrate a cholesterol-independent colocalization of GM1 with EGFR, which was not observed for the transferrin receptor. By contrast, a cholesterol-dependent colocalization was observed for GM1 with GPI-GFP. In the resting state no colocalization was observed between EGFR and GPI-GFP, but stimulation of the cell with EGF resulted in the colocalization at the nanoscale level of EGFR and GPI-GFP. Moreover, EGF induced the enrichment of GPI-GFP in a detergent-free lipid raft fraction. Our results suggest that EGF induces the coalescence of the two types of GM1-containing microdomains that might lead to the formation of signaling platforms.

3.1117 Regulation of the V-ATPase along the Endocytic Pathway Occurs through Reversible Subunit Association and Membrane Localization
Lafourcade, C., Sobo, K., Kieffer-Jaquinod, S., Garin, J. and van der Goot, F.G.
*PloS One, **3(7)**, e2758 (2008)*

The lumen of endosomal organelles becomes increasingly acidic when going from the cell surface to lysosomes. Luminal pH thereby regulates important processes such as the release of internalized ligands from their receptor or the activation of lysosomal enzymes. The main player in endosomal acidification is the vacuolar ATPase (V-ATPase), a multi-subunit transmembrane complex that pumps protons from the cytoplasm to the lumen of organelles, or to the outside of the cell. The active V-ATPase is composed of two multi-subunit domains, the transmembrane V_0 and the cytoplasmic V_1. Here we found that the ratio of membrane associated V_1/Vo varies along the endocytic pathway, the relative abundance of V_1 being higher on late endosomes than on early endosomes, providing an explanation for the higher acidity of late endosomes. We also found that all membrane-bound V-ATPase subunits were associated with detergent resistant membranes (DRM) isolated from late endosomes, raising the possibility that association with lipid-raft like domains also plays a role in regulating the activity of the proton pump. In support of this, we found that treatment of cells with U18666A, a drug that leads to the accumulation of cholesterol in late endosomes, affected acidification of late endosome. Altogether our findings indicate that the activity of the vATPase in the endocytic pathway is regulated both by reversible association/dissociation and the interaction with specific lipid environments.

3.1118 Armet, a UPR-upregulated protein, inhibits cell proliferation and ER stress-induced cell death
Apostolou, A., Shen, Y., Liang, Y., Luo, J. and Fang, S.
*Exp. Cell Res., **314**, 2454-2467 (2008)*

The accumulation of misfolded proteins in the endoplasmic reticulum (ER) causes ER stress that initiates the unfolded protein response (UPR). UPR activates both adaptive and apoptotic pathways, which contribute differently to disease pathogenesis. To further understand the functional mechanisms of UPR,

we identified 12 commonly UPR-upregulated genes by expression microarray analysis. Here, we describe characterization of Armet/MANF, one of the 12 genes whose function was not clear. We demonstrated that the Armet/MANF protein was upregulated by various forms of ER stress in several cell lines as well as by cerebral ischemia of rat. Armet/MANF was localized in the ER and Golgi and was also a secreted protein. Silencing Armet/MANF by siRNA oligos in HeLa cells rendered cells more susceptible to ER stress-induced death, but surprisingly increased cell proliferation and reduced cell size. Overexpression of Armet/MANF inhibited cell proliferation and improved cell viability under glucose-free conditions and tunicamycin treatment. Based on its inhibitory properties for both proliferation and cell death we have demonstrated, Armet is, thus, a novel secreted mediator of the adaptive pathway of UPR.

3.1119 Lipoprotein binding preference of CD36 is altered by filipin treatment
Zhang, J., Chu, W. and Crandall, I.
*Lipids in Health and Disease, **7**, 23-31 (2008)*

The class B scavenger receptor CD36 binds multiple ligands, including oxidized and native lipoprotein species. CD36 and the related receptor SR-B1 have been localized to caveolae, domains that participate in cell signaling, transcytosis, and regulation of cellular cholesterol homeostasis. Previous work has indicated that the ligand preference of CD36 may depend on the cell type in which it is expressed. To determine if the presence or absence of caveolae is the determining factor for lipoprotein preference, we treated CHO-CD36 and C32 cells with filipin. Filipin treatment rapidly increased the binding capacity of CD36 for the native lipoproteins HDL and LDL, but did not affect the binding capacity of CD36 for oxidized LDL. Filipin treatment affected the distribution of caveolin and CD36 suggesting that the presence caveolae may modulate the ligand preference of CD36. However, its molecular mechanism how CD36 and caveolin interaction in regulating lipoprotein transport remains to be further studied.

3.1120 Interaction of Hepatitis C Virus Nonstructural Protein 5A with Core Protein Is Critical for the Production of Infectious Virus Particles
Masaki, T. et al
*J. Virol., **82(16)**, 7964-7976 (2008)*

Nonstructural protein 5A (NS5A) of the hepatitis C virus (HCV) possesses multiple and diverse functions in RNA replication, interferon resistance, and viral pathogenesis. Recent studies suggest that NS5A is involved in the assembly and maturation of infectious viral particles; however, precisely how NS5A participates in virus production has not been fully elucidated. In the present study, we demonstrate that NS5A is a prerequisite for HCV particle production as a result of its interaction with the viral capsid protein (core protein). The efficiency of virus production correlated well with the levels of interaction between NS5A and the core protein. Alanine substitutions for the C-terminal serine cluster in domain III of NS5A (amino acids 2428, 2430, and 2433) impaired NS5A basal phosphorylation, leading to a marked decrease in NS5A-core interaction, disturbance of the subcellular localization of NS5A, and disruption of virion production. Replacing the same serine cluster with glutamic acid, which mimics the presence of phosphoserines, partially preserved the NS5A-core interaction and virion production, suggesting that phosphorylation of these serine residues is important for virion production. In addition, we found that the alanine substitutions in the serine cluster suppressed the association of the core protein with viral genome RNA, possibly resulting in the inhibition of nucleocapsid assembly. These results suggest that NS5A plays a key role in regulating the early phase of HCV particle formation by interacting with core protein and that its C-terminal serine cluster is a determinant of the NS5A-core interaction.

3.1121 Novel Role of Presenilins in Maturation and Transport of Integrin β1
Zou, K. et al
*Biochemistry, **47**, 3370-3378 (2008)*

Presenilins (PSs) play important roles in modulating the trafficking and maturation of several membrane proteins. However, the target membrane proteins whose trafficking and maturation are regulated by PS are largely unknown. By characterizing PS-deficient fibroblasts, we found that integrin β1 maturation is promoted markedly in PS1 and PS2 double-deficient fibroblasts and moderately in PS1- or PS2-deficient fibroblasts; in contrast, nicastrin maturation is completely inhibited in PS1 and PS2 double-deficient fibroblasts. Subcellular fractionation analysis demonstrated that integrin β1 maturation is promoted in the Golgi apparatus. The mature integrin β1 with an increased expression level was delivered to the cell surface, which resulted in an increased cell surface expression level of mature integrin β1 in PS1 and PS2 double-deficient fibroblasts. PS1 and PS2 double-deficient fibroblasts exhibited an enhanced ability to

adhere to culture dishes coated with integrin β1 ligands, namely, fibronectin and laminin. The inhibition of γ-secretase activity enhances neither integrin β1 maturation nor the adhesion of wild-type cells. Moreover, PS deficiency also promoted the maturation of integrins α3 and α5 and the cell surface expression of integrin α3. Integrins α3 and α5 were coimmunoprecipitated with integrin β1, suggesting the formation of the functional heterodimers integrins α3β1 and α5β1. Note that integrin β1 exhibited features opposite those of nicastrin in terms of maturation and trafficking from the endoplasmic reticulum (ER) to the Golgi apparatus in PS1 and PS2 double-deficient fibroblasts. Our results therefore suggest that PS regulates the maturation of membrane proteins in opposite directions and cell adhesion by modulating integrin maturation.

3.1122 Conventional Kinesin Holoenzymes Are Composed of Heavy and Light Chain Homodimers
DeBoer, S.R. et al
*Biochemistry, **47**, 4535-4543 (2008)*

Conventional kinesin is a major microtubule-based motor protein responsible for anterograde transport of various membrane-bounded organelles (MBO) along axons. Structurally, this molecular motor protein is a tetrameric complex composed of two heavy (kinesin-1) chains and two light chain (KLC) subunits. The products of three kinesin-1 (kinesin-1A, -1B, and -1C, formerly KIF5A, -B, and -C) and two KLC (KLC1, KLC2) genes are expressed in mammalian nervous tissue, but the functional significance of this subunit heterogeneity remains unknown. In this work, we examine all possible combinations among conventional kinesin subunits in brain tissue. In sharp contrast with previous reports, immunoprecipitation experiments here demonstrate that conventional kinesin holoenzymes are formed of kinesin-1 homodimers. Similar experiments confirmed previous findings of KLC homodimerization. Additionally, no specificity was found in the interaction between kinesin-1s and KLCs, suggesting the existence of six variant forms of conventional kinesin, as defined by their gene product composition. Subcellular fractionation studies indicate that such variants associate with biochemically different MBOs and further suggest a role of kinesin-1s in the targeting of conventional kinesin holoenzymes to specific MBO cargoes. Taken together, our data address the combination of subunits that characterize endogenous conventional kinesin. Findings on the composition and subunit organization of conventional kinesin as described here provide a molecular basis for the regulation of axonal transport and delivery of selected MBOs to discrete subcellular locations.

3.1123 A Proteomics Approach to Membrane Trafficking
Groen, A.J., de Vries, S.C. and Lilley, K.S.
*Plant Physiol., **147**, 1584-1589 (2008)*

Membrane trafficking, including that of integral membrane proteins as well as peripherally associated proteins, appears to be a vital process common to all eukaryotes. An important element of membrane trafficking is to determine the protein composition of the various endomembrane compartments. A major issue with such a compositional analysis is the difficulty of having to distinguish between resident components involved in specific tasks and the proteins that are in transit through the endomembrane system. Examples of resident proteins include components of the SNARE complex used to target membrane vesicles to different locations in the cell. In the case of functionally important residents, one would expect such proteins to have a fairly precise subcellular localization. In the case of proteins "passing through" an endosomal compartment en route to a final destination, one would expect to find the proteins colocalizing with many membrane compartments.
As is evident from several *Update* articles in this issue, ambiguity exists when employing cytological techniques to identify specific endomembrane compartments, while markers identified based on homology may behave differently in plant cells. Therefore, a proteomics approach based on proteins that would traffic through various parts of the endomembrane system, such as plasma membrane (PM) receptors, would be a welcome addition to membrane-trafficking studies. PM receptors are highly dependent on correct trafficking for their eventual localization, their biological function, and finally their degradation, while recent evidence suggests that endocytosis of PM receptors is an integral part of their biological function.
In this review, first, a short update on endocytosis and endosomal trafficking in Arabidopsis (*Arabidopsis thaliana*) is provided. In this section, we emphasize trafficking of PM receptors as a proteomics tool by looking at how the PM receptors traffic in a time-dependent fashion in order to determine the relationship between different endosomal compartments. Second, we describe the recent progress in advanced

proteomics techniques such as localization of organelle proteins by isotope tagging (LOPIT), by which proteins are assigned to different endosomal compartments.

3.1124 Molecular Identification of a SNAP-25-Like SNARE Protein in Paramecium
Schilde, C., Lutter, K., Kissmehl, R. And Plattner, H.
*Eukaryot. Cell, **7(8)**, 1387-1402 (2008)*

Using database searches of the completed *Paramecium tetraurelia* macronuclear genome with the metazoan SNAP-25 homologues, we identified a single 21-kDa Qb/c-SNARE in this ciliated protozoan, named *P. tetraurelia* SNAP (PtSNAP), containing the characteristic dual heptad repeat SNARE motifs of SNAP-25. The presence of only a single Qb/c class SNARE in *P. tetraurelia* is surprising in view of the multiple genome duplications and the high number of SNAREs found in other classes of this organism. As inferred from the subcellular localization of a green fluorescent protein (GFP) fusion construct, the protein is localized on a variety of intracellular membranes, and there is a large soluble pool of PtSNAP. Similarly, the PtSNAP that is detected with a specific antibody in fixed cells is associated with a number of intracellular membrane structures, including food vacuoles, the contractile vacuole system, and the sites of constitutive endo- and exocytosis. Surprisingly, using gene silencing, we could not assign a role to PtSNAP in the stimulated exocytosis of dense core vesicles (trichocysts), but we found an increased number of food vacuoles in PtSNAP-silenced cells. In conclusion, we identify PtSNAP as a *Paramecium* homologue of metazoan SNAP-25 that shows several divergent features, like resistance to cleavage by botulinum neurotoxins.

3.1125 Reciprocal interaction with G-actin and tropomyosin is essential for aquaporin-2 trafficking
Noda, Y. et al
*J. Cell Biol., **182(3)**, 587-601 (2008)*

Trafficking of water channel aquaporin-2 (AQP2) to the apical membrane and its vasopressin and protein kinase A (PKA)–dependent regulation in renal collecting ducts is critical for body water homeostasis. We previously identified an AQP2 binding protein complex including actin and tropomyosin-5b (TM5b). We show that dynamic interactions between AQP2 and the actin cytoskeleton are critical for initiating AQP2 apical targeting. Specific binding of AQP2 to G-actin in reconstituted liposomes is negatively regulated by PKA phosphorylation. Dual color fluorescence cross-correlation spectroscopy reveals local AQP2 interaction with G-actin in live epithelial cells at single-molecule resolution. Cyclic adenosine monophosphate signaling and AQP2 phosphorylation release AQP2 from G-actin. In turn, AQP2 phosphorylation increases its affinity to TM5b, resulting in reduction of TM5b bound to F-actin, subsequently inducing F-actin destabilization. RNA interference–mediated knockdown and overexpression of TM5b confirm its inhibitory role in apical trafficking of AQP2. These findings indicate a novel mechanism of channel protein trafficking, in which the channel protein itself critically regulates local actin reorganization to initiate its movement.

3.1126 Sensitization to the Lysosomal Cell Death Pathway by Oncogene-Induced Down-regulation of Lysosome-Associated Membrane Proteins 1 and 2
Fehrenbacher, N. et al
*Cancer Res., **68(16)**, 6623-6633 (2008)*

Expression and activity of lysosomal cysteine cathepsins correlate with the metastatic capacity and aggressiveness of tumors. Here, we show that transformation of murine embryonic fibroblasts with *v-H-ras* or *c-src*^{Y527F} changes the distribution, density, and ultrastructure of the lysosomes, decreases the levels of lysosome-associated membrane proteins (LAMP-1 and LAMP-2) in an extracellular signal-regulated kinase (ERK)- and cathepsin-dependent manner, and sensitizes the cells to lysosomal cell death pathways induced by various anticancer drugs (i.e., cisplatin, etoposide, doxorubicin, and siramesine). Importantly, *K-ras* and *erbb2* elicit a similar ERK-mediated activation of cysteine cathepsins, cathepsin-dependent down-regulation of LAMPs, and increased drug sensitivity in human colon and breast carcinoma cells, respectively. Notably, reconstitution of LAMP levels by ectopic expression or by cathepsin inhibitors protects transformed cells against the lysosomal cell death pathway. Furthermore, knockdown of either *lamp1* or *lamp2* is sufficient to sensitize the cells to siramesine-induced cell death and photo-oxidation–induced lysosomal destabilization. Thus, the transformation-associated ERK-mediated up-regulation of cysteine cathepsin expression and activity leads to a decrease in the levels of LAMPs, which in turn contributes to the enhanced sensitivity of transformed cells to drugs that trigger lysosomal membrane permeabilization. These data indicate that aggressive cancers with high cysteine cathepsin levels are

especially sensitive to lysosomal cell death pathways and encourage the further development of lysosome-targeting compounds for cancer therapy.

3.1127 Intravesicular Calcium Release Mediates the Motion and Exocytosis of Secretory Organelles: A STUDY WITH ADRENAL CHROMAFFIN CELLS
Camacho, M., Machado, J.D., Alvarez, J. and Borges, R.
J. Biol. Chem., ***283(33)***, *22383-22389 (2008)*

Nonstructural protein 5A (NS5A) of the hepatitis C virus (HCV) possesses multiple and diverse functions in RNA replication, interferon resistance, and viral pathogenesis. Recent studies suggest that NS5A is involved in the assembly and maturation of infectious viral particles; however, precisely how NS5A participates in virus production has not been fully elucidated. In the present study, we demonstrate that NS5A is a prerequisite for HCV particle production as a result of its interaction with the viral capsid protein (core protein). The efficiency of virus production correlated well with the levels of interaction between NS5A and the core protein. Alanine substitutions for the C-terminal serine cluster in domain III of NS5A (amino acids 2428, 2430, and 2433) impaired NS5A basal phosphorylation, leading to a marked decrease in NS5A-core interaction, disturbance of the subcellular localization of NS5A, and disruption of virion production. Replacing the same serine cluster with glutamic acid, which mimics the presence of phosphoserines, partially preserved the NS5A-core interaction and virion production, suggesting that phosphorylation of these serine residues is important for virion production. In addition, we found that the alanine substitutions in the serine cluster suppressed the association of the core protein with viral genome RNA, possibly resulting in the inhibition of nucleocapsid assembly. These results suggest that NS5A plays a key role in regulating the early phase of HCV particle formation by interacting with core protein and that its C-terminal serine cluster is a determinant of the NS5A-core interaction.

3.1128 Lysyl Oxidase Oxidizes Cell Membrane Proteins and Enhances the Chemotactic Response of Vascular Smooth Muscle Cells
Lucero, H.A. et al
J. Biol. Chem., ***283(35)***, *24103-24117 (2008)*

Lysyl oxidase (LOX) is a potent chemokine inducing the migration of varied cell types. Here we demonstrate that inhibition of LOX activity by β-aminopropionitrile (BAPN) in cultured rat aortic smooth muscle cells (SMCs) reduced the chemotactic response and sensitivity of these cells toward LOX and toward PDGF-BB. The chemotactic activity of PDGF-BB was significantly enhanced in the presence of a non-chemotactic concentration of LOX. We considered the possibility that extracellular LOX may oxidize cell surface proteins, including the PDGF receptor-β (PDGFR-β), to affect PDGF-BB-induced chemotaxis. Plasma membranes purified from control SMC contained oxidized PDGFR-β. The oxidation of this receptor and other membrane proteins was largely prevented in cells preincubated with BAPN. Addition of purified LOX to these cells restored the profile of oxidized proteins toward that of control cells. The high affinity and capacity for the binding of PDGF-BB by cells containing oxidized PDGFR-β was diminished by ~2-fold when compared with cells in which oxidation by LOX was prevented by BAPN. Phosphorylated members of the PDGFR-β-dependent signal transduction pathway, including PDGFR-β, SHP2, AKT1, and ERK1/ERK2 (p44/42 MAPK), turned over faster in BAPN-treated than in control SMCs. LOX knock-out mouse embryonic fibroblasts mirrored the effect obtained with SMCs treated with BAPN. These novel findings suggest that LOX activity is essential to generate optimal chemotactic sensitivity of cells to chemoattractants by oxidizing specific cell surface proteins, such as PDGFR-β.

3.1129 Intramembrane Processing by Signal Peptide Peptidase Regulates the Membrane Localization of Hepatitis C Virus Core Protein and Viral Propagation
Okamoto, K. et al
J. Virol., ***82(17)***, *8349-8361 (2008)*

Hepatitis C virus (HCV) core protein has shown to be localized in the detergent-resistant membrane (DRM), which is distinct from the classical raft fraction including caveolin, although the biological significance of the DRM localization of the core protein has not been determined. The HCV core protein is cleaved off from a precursor polyprotein at the lumen side of Ala^{191} by signal peptidase and is then further processed by signal peptide peptidase (SPP) within the transmembrane region. In this study, we examined the role of SPP in the localization of the HCV core protein in the DRM and in viral propagation. The C terminus of the HCV core protein cleaved by SPP in 293T cells was identified as Phe^{177} by mass spectrometry. Mutations introduced into two residues (Ile^{176} and Phe^{177}) upstream of the cleavage site of

the core protein abrogated processing by SPP and localization in the DRM fraction. Expression of a dominant-negative SPP or treatment with an SPP inhibitor, L685,458, resulted in reductions in the levels of processed core protein localized in the DRM fraction. The production of HCV RNA in cells persistently infected with strain JFH-1 was impaired by treatment with the SPP inhibitor. Furthermore, mutant JFH-1 viruses bearing SPP-resistant mutations in the core protein failed to propagate in a permissive cell line. These results suggest that intramembrane processing of HCV core protein by SPP is required for the localization of the HCV core protein in the DRM and for viral propagation.

3.1130 Ral-regulated interaction between Sec5 and paxillin targets Exocyst to focal complexes during cell migration

Spiczka, K.S. and Yeaman, C.
J. Cell Sci., ***121***, *2880-2891 (2008)*

Changes in cellular behavior that cause epithelial cells to lose adhesiveness, acquire a motile invasive phenotype and metastasize to secondary sites are complex and poorly understood. Molecules that normally function to integrate adhesive spatial information with cytoskeleton dynamics and membrane trafficking probably serve important functions in cellular transformation. One such complex is the Exocyst, which is essential for targeted delivery of membrane and secretory proteins to specific plasma membrane sites to maintain epithelial cell polarity. Upon loss of cadherin-mediated adhesion in Dunning R3327-5'A prostate tumor cells, Exocyst localization shifts from lateral membranes to tips of protrusive membrane extensions. Here, it colocalizes and co-purifies with focal complex proteins that regulate membrane trafficking and cytoskeleton dynamics. These sites are the preferred destination of post-Golgi transport vesicles ferrying biosynthetic cargo, such as α_5-integrin, which mediates adhesion of cells to the substratum, a process essential to cell motility. Interference with Exocyst activity impairs integrin delivery to plasma membrane and inhibits tumor cell motility and matrix invasiveness. Localization of Exocyst and, by extension, targeting of Exocyst-dependent cargo, is dependent on Ral GTPases, which control association between Sec5 and paxillin. Overexpression of Ral-uncoupled Sec5 mutants inhibited Exocyst interaction with paxillin in 5'A cells, as did RNAi-mediated reduction of either RalA or RalB. Reduction of neither GTPase significantly altered steady-state levels of assembled Exocyst in these cells, but did change the observed localization of Exocyst proteins.

3.1131 Multistep, sequential control of the trafficking and function of the multiple sulfatase deficiency gene product, SUMF1 by PDI, ERGIC-53 and ERp44

Fraldi, A. et al
Human Mol. Genet., ***17(17)***, *2610-2621 (2008)*

Sulfatase modifying factor 1 (SUMF1) encodes for the formylglicine generating enzyme, which activates sulfatases by modifying a key cysteine residue within their catalytic domains. SUMF1 is mutated in patients affected by multiple sulfatase deficiency, a rare recessive disorder in which all sulfatase activities are impaired. Despite the absence of canonical retention/retrieval signals, SUMF1 is largely retained in the endoplasmic reticulum (ER), where it exerts its enzymatic activity on nascent sulfatases. Part of SUMF1 is secreted and paracrinally taken up by distant cells. Here we show that SUMF1 interacts with protein disulfide isomerase (PDI) and ERp44, two thioredoxin family members residing in the early secretory pathway, and with ERGIC-53, a lectin that shuttles between the ER and the Golgi. Functional assays reveal that these interactions are crucial for controlling SUMF1 traffic and function. PDI couples SUMF1 retention and activation in the ER. ERGIC-53 and ERp44 act downstream, favoring SUMF1 export from and retrieval to the ER, respectively. Silencing ERGIC-53 causes proteasomal degradation of SUMF1, while down-regulating ERp44 promotes its secretion. When over-expressed, each of three interactors favors intracellular accumulation. Our results reveal a multistep control of SUMF1 trafficking, with sequential interactions dynamically determining ER localization, activity and secretion.

3.1132 Pmp-Like Proteins Pls1 and Pls2 Are Secreted into the Lumen of the Chlamydia trachomatis Inclusion

Jorgensen, I. and Valdivia, R.H.
Infect. Immun., ***76(9)***, *3940-3950 (2008)*

The obligate intracellular pathogen *Chlamydia trachomatis* secretes effector proteins across the membrane of the pathogen-containing vacuole (inclusion) to modulate host cellular functions. In an immunological screen for secreted chlamydial proteins, we identified CT049 and CT050 as potential inclusion membrane-associated proteins. These acidic, nonglobular proteins are paralogously related to the passenger domain of

the polymorphic membrane protein PmpC and, like other Pmp proteins, are highly polymorphic among *C. trachomatis* ocular and urogenital strains. We generated antibodies to these Pmp-like secreted (Pls) proteins and determined by immunofluorescence microscopy that Pls1 (CT049) and Pls2 (CT050) localized to globular structures within the inclusion lumen and at the inclusion membrane. Fractionation of membranes and cytoplasmic components from infected cells by differential and density gradient centrifugation further indicated that Pls1 and Pls2 associated with membranes distinct from the bulk of bacterial and inclusion membranes. The accumulation of Pls1 and, to a lesser extent, Pls2 in the inclusion lumen was insensitive to the type III secretion inhibitor C1, suggesting that this translocation system is not essential for Pls protein secretion. In contrast, Pls secretion and stability were sensitive to low levels of β-lactam antibiotics, suggesting that a functional cell wall is required for Pls secretion from the bacterial cell. Finally, we tested the requirement for these proteins in *Chlamydia* infection by microinjecting anti-Pls1 and anti-Pls2 antibodies into infected cells. Coinjection of anti-Pls1 and -Pls2 antibodies partially inhibited expansion of the inclusion. Because Pls proteins lack classical *sec*-dependent secretion signals, we propose that Pls proteins are secreted into the inclusion lumen by a novel mechanism to regulate events important for chlamydial replication and inclusion expansion.

3.1133 Subcellular distribution of APP/C99 and amyloid-beta peptide is altered in CHO NPC1-null cells compared to CHOwt

Posavec, M., Boskovic, D., Goate, A., Hecimovic, S. and Boskovic, R.
*Alzheimer's and Dementia, **4(4)**, Suppl. 1, T353 (2008)*

Background: A sphingolipid storage disease (SLSD) Niemann Pick type C (NPC) is caused by dysfunction of NPC1 protein which leads to accumulation of free cholesterol and glycosphingolipids in endosomal/lysosomal compartments. It has been recently shown that this defect leads to increased formation of amyloid-beta (Abeta) peptide, and is accompanied by altered localization of presenilin 1 to early/late endosomes. We hypothesized that cholesterol accumulation upon NPC1 loss of function leads to increased APP/C99 localization in endosomes and increased formation of Abeta in these compartments. To test this we monitored subcellular localization of APP/C99 and Abeta between CHO NPC1-null (M12) and CHOwt cells. Methods: The cells were stably transfected with APPsw-6myc construct. Subcellular distribution of APP processing products and organelle markers was analyzed by subcellular fractionation in an Iodixanol gradient. After centrifugation (20h and 100,000xg), fractions were collected from the top and protein (DC Protein Assay, BioRad) and cholesterol concentrations (AmplexRed cholesterol assay, Molecular Probes) were determined in each fraction. After acetone precipitation, APP processing products and organelle markers were detected by western blotting using specific antibodies, while Abeta levels were determined by ELISA assay (BioSource International, Inc.). Results: We observed that the majority of subcellular markers tested (BIP/GRP78, EEA1 and Rab7) showed an altered subcellular distribution in M12 cells compared to CHOwt, indicating that loss of NPC1 leads to altered membrane/protein trafficking. In addition, markedly increased levels of BIP/GRP78 were detected in M12 vs. CHOwt cells, which has been previously reported in another SLSD - GM1 gangliosidosis. Although APP was found in similar fractions of M12 and CHOwt cells, the proportion of APP in early/late endosomes was higher in M12 cells. In these cells we also observed increased levels of Abeta40 in endosomal fractions. Conclusions: Our results suggest that increased formation of Abeta in CHO NPC1-null cells is due to redistribution of APP/C99 to early/late endosomes. We propose that NPC1 dysfunction leads to increased coupling of presenilin 1 and its substrate C99 in endosome compartments generating increased Abeta.

3.1134 Trafficking of chlamydial antigens to the endoplasmic reticulum of infected epithelial cells

Giles, D.K. and Wyrick, P.B.
*Microbes and Infection, **10**, 1494-1503 (2008)*

Confinement of the obligate intracellular bacterium *Chlamydia trachomatis* to a membrane-bound vacuole, termed an inclusion, within infected epithelial cells neither prevents secretion of chlamydial antigens into the host cytosol nor protects chlamydiae from innate immune detection. However, the details leading to chlamydial antigen presentation are not clear. By immunoelectron microscopy of infected endometrial epithelial cells and in isolated cell secretory compartments, chlamydial major outer membrane protein (MOMP), lipopolysaccharide (LPS) and the inclusion membrane protein A (IncA) were localized to the endoplasmic reticulum (ER) and co-localized with multiple ER markers, but not with markers of the endosomes, lysosomes, Golgi nor mitochondria. Chlamydial LPS was also co-localized with CD1d in the ER. Since the chlamydial antigens, contained in everted inclusion membrane vesicles, were found within the host cell ER, these data raise additional implications for antigen processing by infected uterine epithelial cells for classical and non-classical T cell antigen presentation.

3.1135 The GET Complex Mediates Insertion of Tail-Anchored Proteins into the ER Membrane
Schuldiner, M. et al
*Cell, **134**, 634-645 (2008)*

Tail-anchored (TA) proteins, defined by the presence of a single C-terminal transmembrane domain (TMD), play critical roles throughout the secretory pathway and in mitochondria, yet the machinery responsible for their proper membrane insertion remains poorly characterized. Here we show that Get3, the yeast homolog of the TA-interacting factor Asna1/Trc40, specifically recognizes TMDs of TA proteins destined for the secretory pathway. Get3 recognition represents a key decision step, whose loss can lead to misinsertion of TA proteins into mitochondria. Get3-TA protein complexes are recruited for endoplasmic reticulum (ER) membrane insertion by the Get1/Get2 receptor. In vivo, the absence of Get1/Get2 leads to cytosolic aggregation of Get3-TA complexes and broad defects in TA protein biogenesis. In vitro reconstitution demonstrates that the Get proteins directly mediate insertion of newly synthesized TA proteins into ER membranes. Thus, the GET complex represents a critical mechanism for ensuring efficient and accurate targeting of TA proteins.

3.1136 Sulfotransferase 2B1b in human breast: Differences in subcellular localization in African American and Caucasian women
Dumas, N.A., He, D., Frost, A.R. and Falany, C.N.
*J. Steroid Biochem Mol. Biol., **111**, 171-177 (2008)*

Breast cancer (BC) is the most commonly diagnosed cancer among American women; however, the development of post-menopausal BC is significantly lower in African Americans as compared to Caucasians. Hormonal stimulation is important in BC development and differences in the conversion of dehydroepiandrosterone (DHEA) into estrogens may be involved in the lower incidence of post-menopausal BC in African American women. DHEA sulfation by sulfotransferase 2B1b (SULT2B1b) is important in regulating the conversion of DHEA into estrogens in tissues. SULT2B1b is localized in both cytosol and nuclei of some tissues including cancerous and associated-normal breast tissue. Immunohistochemical staining was used to evaluate the total expression and subcellular localization of SULT2B1b in African American and Caucasian breast tissues. Cell fractionation, immunoblot analysis and sulfation assays were used to characterize the subcellular expression and activity of SULT2B1b in BC tissues and T-47D breast adenocarcinoma cells. Immunohistochemical analysis of SULT2B1b showed that African Americans had a significantly greater amount of SULT2B1b in epithelial cells of associated-normal breast tissue as compared to Caucasians. Also, more SULT2B1b in African American associated-normal breast epithelial cells was localized in the nuclei than in Caucasians. Equivalent levels of SULT2B1b were detected in breast adenocarcinoma tissues from both African American and Caucasian women. Nuclei isolation and immunoblot analysis of both BC tissue and human T-47D breast adenocarcinoma cells demonstrated that SULT2B1b is present in nuclei and cytoplasm.

3.1137 Distinct binding sites for the ATPase and substrate-binding domain of human Hsp70 on the cell surface of antigen presenting cells
Zitzler, S., Hellwig, A., Hartl, F-U., Wieland, F. And Diestelkötter-Bachert, P.
*Mol. Immunol., **45**, 3974-3983 (2008)*

Hsp70 has high potential as an immune-adjuvant molecule: it mediates cytokine expression and maturation of antigen presenting cells (APCs) and also elicits a cytotoxic T-lymphocyte (CTL) response to antigenic peptides. How Hsp70 interacts with APCs is only poorly understood. Various surface proteins have been implicated in binding Hsp70 but their role in antigen presentation has remained controversial.
The specific aim of this work was to determine the binding and uptake of human full-length Hsp70 as well as its separate ATPase (N70) and substrate-binding domains (C70) by APCs. Using laser scanning microscopy and FACS analysis, we established the existence of at least two distinct receptors for Hsp70, which are localized to distinct microdomains of the APC membrane. These receptors interact with the N70 and C70 domains of Hsp70, respectively. This observation was supported by the finding of a substantial portion of Hsp70 and C70, but not N70, in a detergent resistant membrane fraction. Accordingly, C70 and N70 did not compete with each other for binding. The bound proteins were rapidly internalized, with N70 and C70 localizing to separate endosomal compartments. Similarly, internalized free and peptide-loaded Hsp70 segregated rapidly within the cell. Efficient cross presentation of antigenic peptide bound to Hsp70 or C70 was demonstrated with the B3Z read out system. Consequently, the interaction of C70 with its putative receptor seems to be responsible for Hsp70-mediated cross presentation. Future studies should

make use of C70 in identifying the uptake receptor of Hsp70–peptide complexes. In addition we could observe a stimulation of uptake of free peptide by preincubation with Hsp70 and N70, but not C70, whereas an Hsp-dependent cytokine secretion could not be detected. Consequently, by employing the individual domains it may be possible to distinguish between the different outcomes of Hsp70 treatment, like immune stimulation, DC maturation and antigen-specific responses.

3.1138 The insulin-regulated aminopeptidase IRAP is colocalised with GLUT4 in the mouse hippocampus - potential role in modulation of glucose uptake in neurones?
Fernando, R.N., Albiston, A.L. and Chai, S.Y.
Eur. J. Neurosci., ***28***, *588-598 (2008)*

It is proposed that insulin-regulated aminopeptidase (IRAP) is the site of action of two peptides, angiotensin IV and LVV-hemorphin 7, which have facilitatory effects on learning and memory. In fat and muscles, IRAP codistributes with the insulin-responsive glucose transporter GLUT4 in specialised vesicles, where it plays a role in the tethering and/or trafficking of these vesicles. This study investigated whether an analogous system exists in two functionally distinct regions of the brain, the hippocampus and the cerebellum. In the hippocampus, IRAP was found in the pyramidal neurones where it exhibited a high degree of colocalisation with GLUT4. Consistent with the role of GLUT4 in insulin-responsive tissues, the glucose transporter was thought to be responsible for facilitating glucose uptake into these pyramidal neurones in response to potassium-induced depolarisation or cAMP activation as the glucose influx was sensitive to indinavir treatment. Angiotensin IV and LVV-hemorphin 7 enhanced this activity-dependent glucose uptake in hippocampal slices. In contrast, in the cerebellum, where the distribution of IRAP was dissociated from GLUT4, the effect of the peptides on glucose uptake was absent. We propose that the modulation of glucose uptake by angiotensin IV and LVV-hemorphin 7 is region-specific and is critically dependent on a high degree of colocalisation between IRAP and GLUT4. These findings also confirm a role for IRAP and GLUT4 in activity-dependent glucose uptake in hippocampal neurones.

3.1139 Separable requirements for cytoplasmic domain of PSGL-1 in leukocyte rolling and signaling under flow
Miner, J.J. et al
Blood, ***112(5)****, 2035-2045 (2008)*

In inflamed venules, leukocytes use P-selectin glycoprotein ligand-1 (PSGL-1) to roll on P-selectin and E-selectin and to activate integrin αLβ2 (lymphocyte function-associated antigen-1, LFA-1) to slow rolling on intercellular adhesion molecule-1 (ICAM-1). Studies in cell lines have suggested that PSGL-1 requires its cytoplasmic domain to localize in membrane domains, to support rolling on P-selectin, and to signal through spleen tyrosine kinase (Syk). We generated "ΔCD" mice that express PSGL-1 without the cytoplasmic domain. Unexpectedly, neutrophils from these mice localized PSGL-1 normally in microvilli, uropods, and lipid rafts. ΔCD neutrophils expressed less PSGL-1 on their surfaces because of inefficient export from the endoplasmic reticulum. Limited digestion of wild-type neutrophils with O-sialoglycoprotein endopeptidase was used to reduce the PSGL-1 density to that on ΔCD neutrophils. At matched PSGL-1 densities, both ΔCD and wild-type neutrophils rolled similarly on P-selectin. However, ΔCD neutrophils rolling on P-selectin did not trigger Syk-dependent activation of LFA-1 to slow rolling on ICAM-1. These data demonstrate that the PSGL-1 cytoplasmic domain is dispensable for leukocyte rolling on P-selectin but is essential to activate β2 integrins to slow rolling on ICAM-1.

3.1140 The presence of an ER exit signal determines the protein sorting upon ER exit in yeast
Watanabe, R., Castillon, G.A., Meury, A. and Riezman, H.
Biochem. J., ***414***, *237-245 (2008)*

In yeast, there are at least two vesicle populations upon ER (endoplasmic reticulum) exit, one containing Gap1p (general aminoacid permease) and a glycosylated α-factor, gpαF (glycosylated proα-factor), and the other containing GPI (glycosylphosphatidylinositol)-anchored proteins, Gas1p (glycophospholipid-anchored surface protein) and Yps1p. We attempted to identify sorting determinants for this protein sorting event in the ER. We found that mutant Gas1 proteins that lack a GPI anchor and/or S/T region (serine- and threonine-rich region), two common characteristic features conserved among yeast GPI-anchored proteins, were still sorted away from Gap1p-containing vesicles. Furthermore, a mutant glycosylated α-factor, gpαGPI, which contains both the GPI anchor and S/T region from Gas1p, still entered Gap1p-containing vesicles, demonstrating that these conserved characteristics do not prevent proteins from entering Gap1p-containing vesicles. gpαF showed severely reduced budding efficiency in the absence of its ER exit

receptor Erv29p, and this residual budding product no longer entered Gap1p-containing vesicles. These results suggest that the interaction of gpαF with Erv29p is essential for sorting into Gap1p-containing vesicles. We compared the detergent solubility of Gas1p and the gpαGPI in the ER with that in ER-derived vesicles. Both GPI-anchored proteins similarly partitioned into the DRM (detergent-resistant membrane) in the ER. Based on the fact that they entered different ER-derived vesicles, we conclude that DRM partitioning of GPI-anchored proteins is not the dominant determinant of protein sorting upon ER exit. Interestingly, upon incorporation into the ER-derived vesicles, gpαGPI was no longer detergent-insoluble, in contrast with the persistent detergent insolubility of Gas1p in the ER-derived vesicles. We present different explanations for the different behaviours of GPI-anchored proteins in distinct ER-derived vesicle populations.

3.1141 Increased basolateral sorting of carcinoembryonic antigen in a polarized colon carcinoma cell line after cholesterol depletion-Implications for treatment of inflammatory bowel disease
Ehehalt, R. et al
World J. Gastroenterol., ***14(10)****, 1528-1533 (2008)*

AIM: To investigate a possible increase of basolateral expression of carcinoembryonic antigen (CEA) by interfering with the apical transport machinery, we studied the effect of cholesterol depletion on CEA sorting and secretion. METHODS: Cholesterol depletion was performed in polarized Caco-2 cells using lovastatin and methyl-beta-cyclodextrin. RESULTS: We show that CEA is predominantly expressed and secreted at the apical surface. Reduction of the cholesterol level of the cell by 40%-50% with lovastatin and methyl-beta-cyclodextrin led to a significant change of the apical-to-basolateral transport ratio towards the basolateral membrane. CONCLUSION: As basolateral expression of CEA has been suggested to have anti-inflamatory properties, Cholesterol depletion of enterocytes might be a potential approach to influence the course of inflammatory bowel disease.

3.1142 The Viral Oncoprotein LMP1 Exploits TRADD for Signaling by Masking Its Apoptotic Activity
Schneider, F. et al
PloS Biology, ***6(1)****, 86-98 (2008)*

The tumor necrosis factor (TNF)-receptor 1–associated death domain protein (TRADD) mediates induction of apoptosis as well as activation of NF-κB by cellular TNF-receptor 1 (TNFR1). TRADD is also recruited by the latent membrane protein 1 (LMP1) oncoprotein of Epstein-Barr virus, but its role in LMP1 signaling has remained enigmatic. In human B lymphocytes, we have generated, to our knowledge, the first genetic knockout of *TRADD* to investigate TRADD's role in LMP1 signal transduction. Our data from TRADD-deficient cells demonstrate that TRADD is a critical signaling mediator of LMP1 that is required for LMP1 to recruit and activate I-κB kinase β (IKKβ). However, in contrast to TNFR1, LMP1-induced TRADD signaling does not induce apoptosis. Searching for the molecular basis for this observation, we characterized the 16 C-terminal amino acids of LMP1 as an autonomous and unique virus-derived TRADD-binding domain. Replacing the death domain of TNFR1 by LMP1′s TRADD-binding domain converts TNFR1 into a nonapoptotic receptor that activates NF-κB through a TRAF6-dependent pathway, like LMP1 but unlike wild-type TNFR1. Thus, the unique interaction of LMP1 with TRADD encodes the transforming phenotype of viral TRADD signaling and masks TRADD's pro-apoptotic function.

3.1143 Vesicular Egress of Non-Enveloped Lytic Parvoviruses Depends on Gelsolin Functioning
Bär, S., Daeffler, L., Rommelaere, J. And Nüesch, J.P.F.
PloS Pathogens, ***4(8)****, 1-11 (2008)*

The autonomous parvovirus Minute Virus of Mice (MVM) induces specific changes in the cytoskeleton filaments of infected permissive cells, causing in particular the degradation of actin fibers and the generation of “actin patches.” This is attributed to a virus-induced imbalance between the polymerization factor N-WASP (Wiscott-Aldrich syndrome protein) and gelsolin, a multifunctional protein cleaving actin filaments. Here, the focus is on the involvement of gelsolin in parvovirus propagation and virus-induced actin processing. Gelsolin activity was knocked-down, and consequences thereof were determined for virus replication and egress and for actin network integrity. Though not required for virus replication or progeny particle assembly, gelsolin was found to control MVM (and related H1-PV) transport from the nucleus to the cell periphery and release into the culture medium. Gelsolin-dependent actin degradation and progeny virus release were both controlled by (NS1)/CKIIα, a recently identified complex between a cellular protein kinase and a MVM non-structural protein. Furthermore, the export of newly synthesized

virions through the cytoplasm appeared to be mediated by (virus-modified) lysomal/late endosomal vesicles. By showing that MVM release, like entry, is guided by the cytoskeleton and mediated by vesicles, these results challenge the current view that egress of non-enveloped lytic viruses is a passive process.

3.1144 Endophilin B1 as a Novel Regulator of Nerve Growth Factor/ TrkA Trafficking and Neurite Outgrowth

Wan, J. et al

J. Neurosci., ***28(36)****, 9002-9012 (2008)*

Neurotrophins and their cognate receptors Trks are important regulators of neuronal survival and differentiation. Recent studies reveal that internalization and trafficking of Trks play a critical role in neurotrophin-mediated signaling. At present, little is known of the molecular events that mediate this process. In the current study, we show that endophilin B1 is a novel regulator of nerve growth factor (NGF) trafficking. We found that endophilin B1 interacts with both TrkA and early endosome marker EEA1. Interestingly, knockdown of endophilin B1 results in enlarged EEA1-positive vesicles in NGF-treated PC12 cells. This is accompanied by increased lysosomal targeting of NGF/TrkA and TrkA degradation, and reduced total TrkA levels. In addition, knockdown of endophilin B1 attenuates Erk1/2 activation in the endosomal fraction after NGF treatment. This is accompanied by a marked inhibition of NGF-induced gene transcription and neurite outgrowth in endophilin B1-knocked down cells. Our observations implicate endophilin B1 as a novel regulator of NGF trafficking, thereby affecting TrkA levels and downstream signaling on endosomes to mediate biological functions of NGF.

3.1145 Conditioning the heart induces formation of signalosomes that interact with mitochondria to open mitoKATP channels

Quinlan, C.L. et al

Am. J. Physiol. Heart Circ. Physiol., ***295****, H953-H961 (2008)*

Perfusion of the heart with bradykinin triggers cellular signaling events that ultimately cause opening of mitochondrial ATP-sensitive K^+ (mitoK_{ATP}) channels, increased H_2O_2 production, inhibition of the mitochondrial permeability transition (MPT), and cardioprotection. We hypothesized that the interaction of bradykinin with its receptor induces the assembly of a caveolar signaling platform (signalosome) that contains the enzymes of the signaling pathway and that migrates to mitochondria to induce mitoK_{ATP} channel opening. We developed a novel method for isolating and purifying signalosomes from Langendorff-perfused rat hearts treated with bradykinin. Fractions containing the signalosomes were found to open mitoK_{ATP} channels in mitochondria isolated from untreated hearts via the activation of mitochondrial PKC-ε. mitoK_{ATP} channel opening required signalosome-dependent phosphorylation of an outer membrane protein. Immunodetection analysis revealed the presence of the bradykinin B_2 receptor only in the fraction isolated from bradykinin-treated hearts. Immunodetection and immunogold labeling of caveolin-3, as well as sensitivity to cholesterol depletion and resistance to Triton X-100, attested to the caveolar nature of the signalosomes. Ischemic preconditioning, ischemic postconditioning, and perfusion with ouabain also led to active signalosome fractions that opened mitoK_{ATP} channels in mitochondria from untreated hearts. These results provide initial support for a novel mechanism for signal transmission from a plasma membrane receptor to mitoK_{ATP} channels.

3.1146 Use of Fluorescence-activated Vesicle Sorting for Isolation of Naked2-associated, Basolaterally Targeted Exocytic Vesicles for Proteomics Analysis

Cao, Z. et al

Mol. Cell. Proteomics, ***7(9)****, 1651-1667 (2008)*

By interacting with the cytoplasmic tail of a Golgi-processed form of transforming growth factor-α (TGF α), Naked2 coats TGFα-containing exocytic vesicles and directs them to the basolateral corner of polarized epithelial cells where the vesicles dock and fuse in a Naked2 myristoylation-dependent manner. These TGFα-containing Naked2-associated vesicles are not directed to the subapical Sec6/8 exocyst complex as has been reported for other basolateral cargo, and thus they appear to represent a distinct set of basolaterally targeted vesicles. To identify constituents of these vesicles, we exploited our finding that myristoylation-deficient Naked2 G2A vesicles are unable to fuse at the plasma membrane. Isolation of a population of myristoylation-deficient, green fluorescent protein-tagged G2A Naked2-associated vesicles was achieved by biochemical enrichment followed by flow cytometric fluorescence-activated vesicle sorting. The protein content of these plasma membrane de-enriched, flow-sorted fluorescent G2A Naked2 vesicles was determined by LC/LC-MS/MS analysis. Three independent isolations were performed, and

389 proteins were found in all three sets of G2A Naked2 vesicles. Rab10 and myosin IIA were identified as core machinery, and Na^+/K^+-ATPase α1 was identified as an additional cargo within these vesicles. As an initial validation step, we confirmed their presence and that of three additional proteins tested (annexin A1, annexin A2, and IQGAP1) in wild-type Naked2 vesicles. To our knowledge, this is the first large scale protein characterization of a population of basolaterally targeted exocytic vesicles and supports the use of fluorescence-activated vesicle sorting as a useful tool for isolation of cellular organelles for comprehensive proteomics analysis.

3.1147 Phosphorylation, lipid raft interaction and traffic of α-synuclein in a yeast model for Parkinson
Zabrocki, P. et al
Biochim. Biophys. Acta., ***1783(10)***, *1767-1780 (2008)*

Parkinson's disease is a neurodegenerative disorder characterized by the formation of Lewy bodies containing aggregated α-synuclein. We used a yeast model to screen for deletion mutants with mislocalization and enhanced inclusion formation of α-synuclein. Many of the mutants were affected in functions related to vesicular traffic but especially mutants in endocytosis and vacuolar degradation combined inclusion formation with enhanced α-synuclein-mediated toxicity. The screening also allowed for identification of casein kinases responsible for α-synuclein phosphorylation at the plasma membrane as well as transacetylases that modulate the α-synuclein membrane interaction. In addition, α-synuclein was found to associate with lipid rafts, a phenomenon dependent on the ergosterol content. Together, our data suggest that toxicity of α-synuclein in yeast is at least in part associated with endocytosis of the protein, vesicular recycling back to the plasma membrane and vacuolar fusion defects, each contributing to the obstruction of different vesicular trafficking routes.

3.1148 Isolation and characterization of mutant animal cell line defective in alkyl-dihydroxyacetonephosphate synthase: Localization and transport of plasmalogens to post-Golgi compartments
Honsho, M., Yagita, Y., Kinoshita, N. and Fujuki, Y.
Biochim. Biophys. Acta, ***1783(10)***, *1857-1865 (2008)*

We herein isolated plasmalogen-deficient Chinese hamster ovary (CHO) mutant, ZPEG251, with a phenotype of normal import of peroxisomal matrix and membrane proteins. In ZPEG251, plasmenylethanolamine (PlsEtn) was severely reduced. Complementation analysis by expression of genes responsible for the plasmalogen biogenesis suggested that alkyl-dihydroxyacetonephosphate synthase (ADAPS), catalyzing the second step of plasmalogen biogenesis, was deficient in ZPEG251. ADAPS mRNA was barely detectable as verified by Northern blot and reverse transcription-PCR analyses. Defect of ADAPS expression was also assessed by immunoblot. As a step toward delineating functional roles of PlsEtn, we investigated its subcellular localization. PlsEtn was localized to post-Golgi compartments and enriched in detergent-resistant membranes. Transport of PlsEtn to post-Golgi compartments was apparently affected by lowering cellular ATP, but not by inhibitors of microtubule assembly and vesicular transport. Partitioning of cholesterol and sphingomyelin, a typical feature of lipid rafts, was not impaired in plasmalogen-deficient cells, including peroxisome assembly-defective mutants, hence suggesting that PlsEtn was not essential for lipid-raft architecture in CHO cells.

3.1149 Occludin oligomeric assembly at tight junctions of the blood-brain barrier is disrupted by peripheral inflammatory hyperalgesia
McCaffrey, G. et al
J. Neurochem., ***106***, *2395-2409 (2008)*

Tight junctions (TJs) at the blood-brain barrier (BBB) dynamically alter paracellular diffusion of blood-borne substances from the peripheral circulation to the CNS in response to external stressors, such as pain, inflammation, and hypoxia. In this study, we investigated the effect of λ-carrageenan-induced peripheral inflammatory pain (i.e., hyperalgesia) on the oligomeric assembly of the key TJ transmembrane protein, occludin. Oligomerization of integral membrane proteins is a critical step in TJ complex assembly that enables the generation of tightly packed, large multiprotein complexes capable of physically obliterating the interendothelial space to inhibit paracellular diffusion. Intact microvessels isolated from rat brains were fractionated by detergent-free density gradient centrifugation, and gradient fractions were analyzed by sodium dodecyl sulfate–polyacrylamide gel electrophoresis/ Western blot. Injection of λ-carrageenan into the rat hind paw produced after 3 h a marked change in the relative amounts of oligomeric, dimeric, and monomeric occludin isoforms associated with different plasma membrane lipid raft domains and

intracellular compartments in endothelial cells at the BBB. Our findings suggest that increased BBB permeability (i.e., leak) associated with λ-carrageenan-induced peripheral inflammatory pain is promoted by the disruption of disulfide-bonded occludin oligomeric assemblies, which renders them incapable of forming an impermeant physical barrier to paracellular transport.

3.1150 Cathepsin D Is the Main Lysosomal Enzyme Involved in the Degradation of α-Synuclein and Generation of Its Carboxy-Terminally Truncated Species
Sevlever, D., Jiang, P. and Yen, S-H.C.
*Biochemistry, **47**, 9678-9687 (2008)*

α-Synuclein is likely to play a key role in the development of Parkinson's disease as well as other synucleinopathies. In animal models, overexpression of full-length or carboxy-terminally truncated α-synuclein has been shown to produce pathology. Although the proteosome and lysosome have been proposed to play a role in the degradation of α-synuclein, the enzyme(s) involved in α-synuclein clearance and generation of its carboxy-terminally truncated species have not been identified. In this study, the role of cathepsin D and calpain I in these processes was analyzed. *In vitro* experiments, using either recombinant or endogenous α-synuclein as substrates and purified cathepsin D or lysosomes, demonstrated that cathepsin D degraded α-synuclein very efficiently, and that limited proteolysis resulted in the generation of carboxy-terminally truncated species. Purified calpain I also cleaved α-synuclein, but carboxy-terminally truncated species were not the main cleavage products, and calpain I activity present in cellular lysates was not able to degrade the protein. Knockdown of cathepsin D in cells overexpressing wild-type α-synuclein increased total α-synuclein levels by 28% and lysosomal α-synuclein by 2-fold. In *in vitro* experiments, pepstatin A completely blocked the degradation of α-synuclein in purified lysosomes. Furthermore, lysosomes isolated from cathepsin D knockdown cells showed a marked reduction in α-synuclein degrading activity, indicating that cathepsin D is the main lysosomal enzyme involved in α-synuclein degradation. Our findings suggest that upregulation of cathepsin D could be an additional therapeutic strategy to lessen α-synuclein burden in synucleinopathies.

3.1151 Discrimination between exosomes and HIV-1: Purification of both vesicles from cell-free supernatants
Cantin, R., Diou, J., Belanger, D., Tremblay, A.M. and Gilbert, C.
*J. Immunol. Methods, **338**, 21-30 (2008)*

Although enveloped retroviruses bud from the cell surface of T lymphocytes, they use the endocytic pathway and the internal membrane of multivesicular bodies for their assembly and release from macrophages and dendritic cells (DCs). Exosomes, physiological nanoparticles produced by hematopoietic cells, egress from this same pathway and are similar to retroviruses in terms of size, density, the molecules they incorporate and their ability to activate immune cells. Retroviruses are therefore likely to contaminate *in vitro* preparations of exosomes and vice versa and sucrose gradients are inefficient at separating them. However, we have found that their sedimentation velocities in an iodixanol (Optiprep™) velocity gradient are sufficiently different to allow separation and purification of both vesicles. Using acetylcholinesterase as an exosome marker, we demonstrate that Optiprep™ velocity gradients are very efficient in separating exosomes from HIV-1 particles produced on 293T cells, primary $CD4^+$ T cells, macrophages or DCs, with exosomes collecting at 8.4–12% iodixanol and HIV-1 at 15.6%. We also show that immunodepletion with an anti-acetylcholinesterase antibody rapidly produces highly purified preparations of HIV-1 or exosomes. These findings have applications in fundamental research on exosomes and/or AIDS, as well as in clinical applications where exosomes are involved, more specifically in tumour therapy or in gene therapy using exosomes generated from DCs genetically modified by transfection with virus.

3.1152 Uptake of long chain fatty acids is regulated by dynamic interaction of FAT/CD36 with cholesterol/sphingolipid enriched microdomains (lipid rafts)
Ehehalt, R. et al
*BMC Cell Biol., **9**, 45-56 (2008)*

Background
Mechanisms of long chain fatty acid uptake across the plasma membrane are important targets in treatment of many human diseases like obesity or hepatic steatosis. Long chain fatty acid translocation is achieved by a concert of co-existing mechanisms. These lipids can passively diffuse, but certain membrane proteins can also accelerate the transport. However, we now can provide further evidence that not only proteins but also lipid microdomains play an important part in the regulation of the facilitated uptake process.

Methods
Dynamic association of FAT/CD36 a candidate fatty acid transporter with lipid rafts was analysed by isolation of detergent resistant membranes (DRMs) and by clustering of lipid rafts with antibodies on living cells. Lipid raft integrity was modulated by cholesterol depletion using methyl-β-cyclodextrin and sphingolipid depletion using myriocin and sphingomyelinase. Functional analyses were performed using an [3H]-oleate uptake assay.
Results
Overexpression of FAT/CD36 and FATP4 increased long chain fatty acid uptake. The uptake of long chain fatty acids was cholesterol and sphingolipid dependent. Floating experiments showed that there are two pools of FAT/CD36, one found in DRMs and another outside of these domains. FAT/CD36 co-localized with the lipid raft marker PLAP in antibody-clustered domains at the plasma membrane and segregated away from the non-raft marker GFP-TMD. Antibody cross-linking increased DRM association of FAT/CD36 and accelerated the overall fatty acid uptake in a cholesterol dependent manner. Another candidate transporter, FATP4, was neither present in DRMs nor co-localized with FAT/CD36 at the plasma membrane.
Conclusion
Our observations suggest the existence of two pools of FAT/CD36 within cellular membranes. As increased raft association of FAT/CD36 leads to an increased fatty acid uptake, dynamic association of FAT/CD36 with lipid rafts might regulate the process. There is no direct interaction of FATP4 with lipid rafts or raft associated FAT/CD36. Thus, lipid rafts have to be considered as targets for the treatment of lipid disorders.

3.1153 The unique architecture of Bunyamwera virus factories around the Golgi complex
Fontana, J., Lopez-Montero, N., Elliott, R.M., Fernandez, J.J. and Risco, C.
Cell. Microbiol., ***10(10)****, 2112-2028 (2008)*

Viral factories are novel structures built by viruses in infected cells. During their construction organelles are recruited and build a large scaffold for viral replication and morphogenesis. We have studied how a bunyavirus uses the Golgi to build the factory. With the help of confocal and 3D ultrastructural imaging together with molecular mapping *in situ* and *in vitro* we have characterized a tubular structure that harbours the viral replication complexes in a globular domain. Numerous ribonucleoproteins were released from purified tubes disrupted *in vitro*. Actin and myosin I were identified by peptide mass fingerprinting in isolated tubes while actin and the viral NSm non-structural protein were detected in the tubes' internal proteinaceous scaffold by immunogold labelling. Studies with NSm deletion mutants and drugs affecting actin showed that both NSm and actin are key factors for tube and virus assembly in Golgi. Three-dimensional reconstructions based on oriented serial sections of infected cells showed that tubes anchor cell organelles to Golgi stacks and make contacts with intracellular viruses. We propose that this new structure, unique among enveloped viruses, assembles in association with the most stable component of Golgi stacks, the actin-containing matrix scaffold, connecting viral replication and morphogenesis inside viral factories.

3.1154 Absence of 2-Hydroxylated Sphingolipids Is Compatible with Normal Neural Development But Causes Late-Onset Axon and Myelin Sheath Degeneration
Zöller, I. et al
J. Neurosci., ***28(39)****, 9741-9754 (2008)*

Sphingolipids containing 2-hydroxylated fatty acids are among the most abundant lipid components of the myelin sheath and therefore are thought to play an important role in formation and function of myelin. To prove this hypothesis, we generated mice lacking a functional fatty acid 2-hydroxylase (FA2H) gene. FA2H-deficient ($FA2H^{-/-}$) mice lacked 2-hydroxylated sphingolipids in the brain and in peripheral nerves. In contrast, nonhydroxylated galactosylceramide was increased in $FA2H^{-/-}$ mice. However, oligodendrocyte differentiation examined by *in situ* hybridization with cRNA probes for proteolipid protein and PDGFα receptor and the time course of myelin formation were not altered in $FA2H^{-/-}$ mice compared with wild-type littermates. Nerve conduction velocity measurements of sciatic nerves revealed no significant differences between $FA2H^{-/-}$ and wild-type mice. Moreover, myelin of $FA2H^{-/-}$ mice up to 5 months of age appeared normal at the ultrastructural level, in the CNS and peripheral nervous system. Myelin thickness and g-ratios were normal in $FA2H^{-/-}$ mice. Aged (18-month-old) $FA2H^{-/-}$ mice, however, exhibited scattered axonal and myelin sheath degeneration in the spinal cord and an even more pronounced loss of stainability of myelin sheaths in sciatic nerves. These results show that structurally and functionally

normal myelin can be formed in the absence of 2-hydroxylated sphingolipids but that its long-term maintenance is strikingly impaired. Because axon degeneration appear to start rather early with respect to myelin degenerations, these lipids might be required for glial support of axon function.

3.1155 Kinesin KIF4 Regulates Intracellular Trafficking and Stability of the Human Immunodeficiency Virus Type 1 Gag Polyprotein
Martinez, N., Xue, X., Berro, R.G., Kreitzer, G. and Resh, M.D.
J. Virol., ***82(20)***, *9937-9950 (2008)*

Retroviral Gag proteins are synthesized as soluble, myristoylated precursors that traffic to the plasma membrane and promote viral particle production. The intracellular transport of human immunodeficiency virus type 1 (HIV-1) Gag to the plasma membrane remains poorly understood, and cellular motor proteins responsible for Gag movement are not known. Here we show that disrupting the function of KIF4, a kinesin family member, slowed temporal progression of Gag through its trafficking intermediates and inhibited virus-like particle production. Knockdown of KIF4 also led to increased Gag degradation, resulting in reduced intracellular Gag protein levels; this phenotype was rescued by reintroduction of KIF4. When KIF4 function was blocked, Gag transiently accumulated in discrete, perinuclear, nonendocytic clusters that colocalized with endogenous KIF4, with Ubc9, an E2 SUMO-1 conjugating enzyme, and with SUMO. These studies identify a novel transit station through which Gag traffics en route to particle assembly and highlight the importance of KIF4 in regulating HIV-1 Gag trafficking and stability.

3.1156 Fusion of Enhanced Green Fluorescent Protein to the Pseudorabies Virus Axonal Sorting Protein Us9 Blocks Anterograde Spread of Infection in Mammalian Neurons
Lyman, M.G:, Curanovic, D., Brideau, A.D. and Enquist, L.W.
J. Virol., ***82(20)***, *10308-10311 (2008)*

Pseudorabies virus encodes a membrane protein (Us9) that is essential for the axonal sorting of virus particles within neurons and anterograde spread in the mammalian nervous system. Enhanced green fluorescent protein (GFP)-tagged Us9 mimicked the trafficking properties of the wild-type protein in nonneuronal cells. We constructed a pseudorabies virus strain that expressed Us9-GFP and tested its spread capabilities in the rat visual system and in primary neuronal cultures. We report that Us9-EGFP does not promote anterograde spread of infection and may disrupt packing of viral membrane proteins in lipid rafts, an essential step for Us9-mediated axonal sorting.

3.1157 An epidermal growth factor (EGF) -dependent interaction between GIT1 and sorting nexin 6 promotes degradation of the EGF receptor
Cavet, M.E., Pang, J., Yin, G. And Berk, B.C.
FASEB J., ***22(10)***, *3607-3616 (2008)*

G-protein coupled receptor (GPCR) kinase-2 interacting protein 1 (GIT1) is a multifunctional scaffolding protein that regulates epidermal growth factor receptor (EGFR) signaling pathways. We demonstrate that GIT1 interacts with sorting nexin 6 (SNX6), a member of the SNX family that increases EGFR trafficking between endosomes and lysosomes, thereby enhancing EGFR degradation. The GIT1-SNX6 interaction is increased 3-fold after treatment with EGF for 60 min. The second coiled-coil domain (CC2; aa 424–474) of GIT1 mediates binding to SNX6. Subcellular fractionation and confocal microscopy data indicate that GIT1 and SNX6 interact in endosomes. Knockdown of GIT1 expression by small interfering RNA decreased the rate of EGF-induced EGFR degradation. Expression of exogenous GIT1 or SNX6 alone did not alter EGFR degradation; however, coexpression of GIT1 and SNX6 decreased EGFR levels both basally and in response to EGF. In contrast, expression of GIT1(CC2 deleted) and SNX6 did not reduce EGFR levels, demonstrating that the interaction between GIT1 and SNX6 was required to regulate EGFR trafficking. Phosphorylation of the EGFR substrate phospholipase C-γ was decreased by coexpression of GIT1 and SNX6. These data demonstrate an endosomal, EGF-regulated interaction between SNX6 and GIT1 that enhances degradation of the EGFR, and thereby alters EGFR signaling. Our findings suggest a new role for GIT1 in tyrosine kinase receptor trafficking.—Cavet, M. E., Pang, J., Yin, G., Berk, B. C. An epidermal growth factor (EGF)-dependent interaction between GIT1 and sorting nexin 6 promotes degradation of the EGF receptor.

3.1158 Formation and function of ceramide-enriched membrane platforms with CD38 during M1-receptor stimulation in bovine coronary arterial myocytes
Jia, S-J. et al

*Am. J. Physiol. Heart Circ. Physiol., **295**, H1743-H1752 (2008)*

CD38 contains an ADP ribosylcyclase domain that mediates intracellular Ca^{2+} signaling by the production of cyclic ADP-ribose (cADPR), but the mechanisms by which the agonists activate this enzyme remain unclear. The present study tested a hypothesis that a special lipid-raft (LR) form, ceramide-enriched lipid platform, contributes to CD38 activation to produce cADPR in response to muscarinic type 1 (M_1) receptor stimulation in bovine coronary arterial myocytes (CAMs). By confocal microscopic analysis, oxotremorine (Oxo), an M_1 receptor agonist, was found to increase LR clustering on the membrane with the formation of a complex of CD38 and LR components such as GM_1, acid sphingomyelinase (ASMase), and ceramide, a typical ceramide-enriched macrodomain. At 80 μM, Oxo increased LR clustering by 78.8%, which was abolished by LR disruptors, methyl-β-cyclodextrin (MCD), or filipin. With the use of a fluorescence resonance energy transfer (FRET) technique, 15.5 ± 1.9% energy transfer rate (vs. 5.3 ± 0.9% of control) between CD38 and LR component, ganglioside M_1 was detected, further confirming the proximity of both molecules. In the presence of MCD or filipin, there were no FRET signals detected. In floated detergent-resistant membrane fractions, CD38 significantly increased in LR fractions of CAMs treated by Oxo. Moreover, MCD or filipin attenuated Oxo-induced production of cADPR via CD38. Functionally, Oxo-induced intracellular Ca^{2+} release and coronary artery constriction via cADPR were also blocked by LR disruption or ASMase inhibition. These results provide the first evidence that the formation of ceramide-enriched lipid macrodomains is crucial for Oxo-induced activation of CD38 to produce cADPR in CAMs, and these lipid macrodomains mediate transmembrane signaling of M_1 receptor activation to produce second messenger cADPR.

3.1159 Determination of the Topology of the Hydrophobic Segment of Mammalian Diacylglycerol Kinase Epsilon in a Cell Membrane and Its Relationship to Predictions from Modeling
Decaffmeyer, M. et al
*J. Mol. Biol., **383**, 797-809 (2008)*

The epsilon isoform of diacylglycerol kinase (DGKε) is unique among mammalian DGKs in having a segment of hydrophobic amino acids comprising approximately residues 20 to 41. Several algorithms predict this segment to be a transmembrane (TM) helix. Using PepLook, we have performed an *in silico* analysis of the conformational preference of the segment in a hydrophobic environment comprising residues 18 to 42 of DGKε. We find that there are two distinct groups of stable conformations, one corresponding to a straight helix that would traverse the membrane and the second corresponding to a bent helix that would enter and leave the same side of the membrane. Furthermore, the calculations predict that substituting the Pro32 residue in the hydrophobic segment with an Ala will cause the hydrophobic segment to favor a TM orientation. We have expressed the P32A mutant of DGKε, with a FLAG tag (an N-terminal 3×FLAG epitope tag) at the amino terminus, in COS-7 cells. We find that this mutation causes a large reduction in both k_{cat} and K_m while maintaining k_{cat}/K_m constant. Specificity of the P32A mutant for substrates with polyunsaturated acyl chains is retained. The P32A mutant also has higher affinity for membranes since it is more difficult to extract from the membrane with high salt concentration or high pH compared with the wild-type DGKε. We also evaluated the topology of the proteins with confocal immunofluorescence microscopy using NIH 3T3 cells. We find that the FLAG tag at the amino terminus of the wild-type enzyme is not reactive with antibodies unless the cell membrane is permeabilized with detergent. We also demonstrate that at least a fraction of the wild-type DGKε is present in the plasma membrane and that comparable amounts of the wild-type and P32A mutant proteins are in the plasma membrane fraction. This indicates that in these cells the hydrophobic segment of the wild-type DGKε is not TM but takes up a bent conformation. In contrast, the FLAG tag at the amino terminus of the P32A mutant is exposed to antibody both before and after membrane permeabilization. This modeling approach thus provides an explanation, not provided by simple predictive algorithms, for the observed topology of this protein in cell membranes. The work also demonstrates that the wild-type DGKε is a monotopic protein.

3.1160 Cripto recruits Furin and PACE4 and controls Nodal trafficking during proteolytic maturation
Blancet, M-H. et al
*EMBO J., **27**, 2580-2591 (2008)*

The glycosylphosphatidylinositol (GPI)-anchored proteoglycan Cripto binds Nodal and its type I receptor Alk4 to activate Smad2,3 transcription factors, but a role during Nodal precursor processing has not been described. We show that Cripto also binds the proprotein convertases Furin and PACE4 and localizes

Nodal processing at the cell surface. When coexpressed as in early embryonic cells, Cripto and uncleaved Nodal already associated during secretion, and a Cripto-interacting region in the Nodal propeptide potentiated the effect of proteolytic maturation on Nodal signalling. Disruption of the trans-Golgi network (TGN) by brefeldin A blocked secretion, but export of Cripto and Nodal to the cell surface was not inhibited, indicating that Nodal is exposed to extracellular convertases before entering the TGN/endosomal system. Density fractionation and antibody uptake experiments showed that Cripto guides the Nodal precursor in detergent-resistant
membranes to endocytic microdomains marked by GFP–Flotillin. We conclude that Nodal processing and endocytosis are coupled in signal-receiving cells.

3.1161 Effects of Monoglycerides on P-Glycoprotein: Modulation of the Activity and Expression in Caco-2 Cell Monolayers

Barta, C.A., Sachs-Barrable, K., Feng, F. and Wasan, K.M.
Mol. Pharmaceut., ***5(5)****, 863-875 (2008)*

The purpose of this study was to analyze the effects of two common monoglyceride components of lipid excipients, 1-monoolein and 1-monostearin, on the activity and expression of P-glycoprotein (P-gp) in Caco-2 cells. Non-cytotoxic concentrations of 1-monoolein and 1-monostearin were determined by assessing membrane permeability and mitochondrial activity in Caco-2 cells, a human colon adenocarcinoma cell line. Concentrations of 500 and 100 μM were used to evaluate P-gp activity through Rh123 accumulation and bifunctional transport studies. The P-gp protein expression levels were quantified through the use of immunoblots. The changes in cell membrane fluidity and nuclear membrane integrity upon the addition of monoglycerides were analyzed by fluorescence anisotropy using DPH and TMA-DPH as the fluorescent labels and by using increasing salt concentrations to release the nuclear contents, respectively. The absorptive flux (apical to basolateral) in the bifunctional transport studies was not found to be statistically significant for the non-cytotoxic concentrations of 1-monoolein and 1-monostearin. However, treatments of 500 and 100 μM of 1-monoolein or 1-monostearin displayed statistically lowered efflux (basolateral to apical, $P < 0.05$) compared to the controls (7.9 ± 0.8, $12.9 \pm 2.6 \times 10^6$ cm/s for 1-monoolein or 11.1 ± 2.0, $11.4 \pm 2.3 \times 10^6$ cm/s for 1-monostearin, respectively, compared to the untreated control, $21.1 \pm 2.9 \times 10^6$ cm/s, $n = 5$). Rh123 accumulation was also found to be enhanced upon 24 h incubation with both concentrations of the monoglycerides; however, only concentrations of 500 μM of the monoglycerides were shown to significantly reduce the P-gp protein expression. The results from this study suggest that these two monoglycerides, common components in various lipid excipients, are inhibitors of P-gp.

3.1162 CDK5-dependent Phosphorylation of the Rho Family GTPase TC10α Regulates Insulin-stimulated GLUT4 Translocation

Okada, S. et al
J. Biol. Chem., ***283(51)****, 35455-35463 (2008)*

Insulin stimulation results in the activation of cyclin-dependent kinase-5 (CDK5) in lipid raft domains via a Fyn-dependent phosphorylation on tyrosine residue 15. In turn, activated CDK5 phosphorylates the Rho family GTP-binding protein TC10α on threonine 197 that is sensitive to the CDK5 inhibitor olomoucine and blocked by small interfering RNA-mediated knockdown of CDK5. The phosphorylation deficient mutant T197A-TC10α was not phosphorylated and excluded from the lipid raft domain, whereas the phosphorylation mimetic mutant (T197D-TC10α) was lipid raft localized. Insulin resulted in the GTP loading of T197D-TC10α but not T197A-TC10α and in parallel, T197D-TC10α but not T197A-TC10α depolymerized cortical actin and inhibited insulin-stimulated GLUT4 translocation. These data demonstrate that CDK5-dependent phosphorylation maintains TC10α in lipid raft compartments thereby disrupting cortical actin, whereas subsequent dephosphorylation of TC10α through inactivation of CDK5 allows for the re-assembly of F-actin. Because cortical actin reorganization is required for insulin-stimulated GLUT4 translocation, these data are consistent with a CDK5-dependent TC10α cycling between lipid raft and non-lipid raft compartments.

3.1163 Bluetongue Virus Outer Capsid Protein VP5 Interacts with Membrane Lipid Rafts via a SNARE Domain

Bhattacharya, B. and Roy, P.
J. Virol., ***82(21)****, 10600-10612 (2008)*

Bluetongue virus (BTV) is a nonenveloped double-stranded RNA virus belonging to the family *Reoviridae*. The two outer capsid proteins, VP2 and VP5, are responsible for virus entry. However, little is known about the roles of these two proteins, particularly VP5, in virus trafficking and assembly. In this study, we used density gradient fractionation and methyl beta cyclodextrin, a cholesterol-sequestering drug, to demonstrate not only that VP5 copurifies with lipid raft domains in both transfected and infected cells, but also that raft domain integrity is required for BTV assembly. Previously, we showed that BTV nonstructural protein 3 (NS3) interacts with VP2 and also with cellular exocytosis and ESCRT pathway proteins, indicating its involvement in virus egress (A. R. Beaton, J. Rodriguez, Y. K. Reddy, and P. Roy, *Proc. Natl. Acad. Sci. USA* 99:13154-13159, 2002; C. Wirblich, B. Bhattacharya, and P. Roy *J. Virol.* **80**:460-473, 2006). Here, we show by pull-down and confocal analysis that NS3 also interacts with VP5. Further, a conserved membrane-docking domain similar to the motif in synaptotagmin, a protein belonging to the SNARE (soluble *N*-ethylmaleimide-sensitive fusion attachment protein receptor) family was identified in the VP5 sequence. By site-directed mutagenesis, followed by flotation and confocal analyses, we demonstrated that raft association of VP5 depends on this domain. Together, these results indicate that VP5 possesses an autonomous signal for its membrane targeting and that the interaction of VP5 with membrane-associated NS3 might play an important role in virus assembly.

3.1164 The yeast *O*-acyltransferase Gup1p interferes in lipid metabolism with direct consequences on the sphingolipid-sterol-ordered domains integrity/assembly
Ferreira, C. and Lucas, C.
*Biochim. Biophys. Acta, **1778**, 2648-2653 (2008)*

Saccharomyces cerevisiae Gup1p is a membrane-bound *O*-acyltransferase. Previous works involved *GUP1* in a wide range of crucial processes for cell preservation and functioning. These include cytoskeleton polarization and secretory/endocytic pathway, GPI-anchor remodelling, wall composition and integrity, and membrane lipids, with a reduction in phospholipids and an increase in acylglycerols. DRM fractions were found in considerably lower amounts in *gup1*Δ than in wt strain. Additionally, the proteins presumably associated with lipid micro domains, Gas1p and Pma1p, were present in much smaller amounts in the mutant DRMs. Pma1p is also found in minor quantities in the whole cells extracts of the *gup1*Δ mutant. Accordingly, H^+-ATPase activity was reduced in about 40%. Deletion of *GUP1* resulted in higher sensibility to specific sphingolipid biosynthesis inhibitors and a notorious resistance to ergosterol biosynthesis inhibitors. Furthermore, the majority of mutant cells displayed an even (less punctuated) sterol distribution. The present work presents improvements to DRMs extraction methodology and filipin-sterol staining, provides evidence supporting that Gup1p is involved in lipid metabolism and shows the direct consequences of its absence on the plasma membrane sphingolipid-sterol-ordered domains integrity/assembly.

3.1165 Autocrine activity of tumor-derived membrane vesicles
Hong, B.S., Choi, E.Y., Yoon, Y.J. and Gho, Y.S.
*Eur. J. Cancer Suppl., **6(12)**, 96 (2008)*

Background: Actively growing tumor cells release membrane vesicles into extracellular milieu, and the rate of shedding increases in malignant tumors. Tumor-derived membrane vesicles (TMVs), enriched in most surface antigens and proteases derived from their originating cells, are nowadays gaining attention as important mediators of cell-to-cell communication facilitating processes such as angiogenesis and immune modulation with paracrine functions. Since TMVs have the potential to affect to tumor cells themselves, the role of TMVs in autocrine signals to tumor cells has been investigated.
Material and Methods: We isolated TMVs from SW480, human colorectal adenocarcinoma cells by ultracentrifugation onto sucrose cushion and iodixanol gradients. We characterized TMVs with Western blotting using membrane vesicles markers, density in an iodixanol gradient, and transmission electron microscopy. Cell proliferation was determined by [3H]- thymidine incorporation and cell migration assay was performed in a 48-well microchemotaxis chamber. Intracellular Ca2+ mobilization was determined with the fluorescent Ca2+ indicator fluo-3/AM, and AlexaFluor 488- conjugated phalloidine was used for imaging actin stress fiber formation.
Results: The purified TMVs settled at a density of ~1.110 g/mL, presenting membrane vesicles markers (CD63 and CD81), and almost all TMVs were spherical and bi-layered vesicles ranging from 40 to 150 nm in size. TMVs stimulated proliferation of tumor cells in a dose-dependent manner, with a maximum effect of 2.4±0.2-fold increases upon exposure to 5 mg/ml of TMVs. TMVs increased migration of tumor cells in a dose-dependent manner, with a maximum effect of 4.1±0.9-fold increases upon exposure to 1 mg/ml of TMVs. The treatment of 1 mg/ml of TMVs to fluo-3/AM-loaded tumor cells caused increased intracellular

free Ca2+ release into the cytosol. Moreover, formation of actin stress fibers was enhanced by the treatment of
1 mg/ml of TMVs for 30 min. Theses results suggest that TMVs may deliver autocrine signals to target tumor cells.
Conclusion: We suggest that TMVs may be involved in promoting autocrine signaling to tumor themselves, neighboring or distant tumor cells for the rapid induction of proliferation, migration, as well as survival.
Therefore, modulating biogenesis and functions of TMVs may be potential novel therapeutic strategies for treating pathological states including malignant tumors.

3.1166 Ceramide and raft signaling are linked with each other in UVA radiation-induced gene expression
Grether-Beck, S. et al
*Oncogene, **27**, 4768-4778 (2008)*

Solar ultraviolet A (UVA) (320–400 nm) radiation-induced gene expression in keratinocytes is initiated at the
level of the cell membrane via generation of singlet oxyge and subsequent formation of ceramide from sphingomyelin. We now report that the UVA response also involves raft signaling and that ceramide and raft signaling are linked with each other. Upon UVA irradiation, the lipid composition of rafts decreased 40% in sphingomyelinand 60% in cholesterol (Chol). Also, decrease of Chol increased the susceptibility towards UVA-induced gene expression, whereas increase of Chol completely abolished their capacity to generate signaling ceramides and to mount the subsequent UVA response. This inhibition was not associated with UVA-induced Chol oxidation and was also seen after treatment of cells with plant sterols. The UVA responsiveness depended on the ratio of Chol versus ceramide in rafts. A ratio smaller than 1 permitted
initiation and transduction of the signaling response, whereas a ratio greater than 1, for example, upon sterol
pretreatment, abolished this response, indicating that UVA radiation-induced ceramide signaling is controlled
by the lipid composition of rafts.

3.1167 Involvement of miltefosine-mediated ERK activation in glioma cell apoptosis through Fas regulation
Tewari, R., Sharma, V., Koul, N. and Sen, E.
*J. Neurochem., **107(3)**, 616-627 (2008)*

The anti-neoplastic property of alkyl phospholipids has been tested for the treatment of several malignancies. In this study, we evaluated the efficacy of miltefosine (Hexadecylphosphocholine – an alkyl phospholipids analogue) on glioblastoma multiforme. In this study, we demonstrate that miltefosine-induced apoptosis is accompanied by elevated Fas, Fas-associated death domain (FADD) expression, caspase-8 activity and the increased distribution of Fas and FADD towards lipid raft microdomain to form death inducing signaling complex. Treatment with miltefosine resulted in increase in Ras, extracellular signal-regulated kinase (ERK) and p38MAPK activity. Expression of dominant-negative Ras (Ras N17) attenuated miltefosine-mediated apoptosis. Although inhibition of both ERK and p38MAPK decreased the pro-apoptotic effects of miltefosine, it was the inhibition of ERK and not p38MAPK activation that decreased Fas and FADD expression. An ERK-dependent increase in the expression of γH2AX-involved in response to DNA double-stranded breaks was also observed. Taken together, our findings suggest the involvement of ERK activation in miltefosine-induced glioma cell apoptosis.

3.1168 Delta Protein Kinase C Interacts with the d Subunit of the F1F0 ATPase in Neonatal Cardiac Myocytes Exposed to Hypoxia or Phorbol Ester: IMPLICATIONS FOR F1F0 ATPase REGULATION
Nguyen, T., Ogbi, M. and Johnson, J.A.
*J. Biol. Chem., **283(44)**, 29831-29840 (2008)*

Mitochondrial protein kinase C isozymes have been reported to mediate both cardiac ischemic preconditioning and ischemia/reperfusion injury. In addition, cardiac preconditioning improves the recovery of ATP levels after ischemia/reperfusion injury. We have, therefore, evaluated protein kinase C modulation of the F_1F_0 ATPase in neonatal cardiac myocytes. Exposure of cells to 3 or 100 nM 4β-phorbol 12-myristate-13-acetate induced co-immunoprecipitation of δprotein kinase C (but not α, ϵ, or ζprotein

kinase C) with the d subunit of the F_1F_0 ATPase. This co-immunoprecipitation correlated with 40 ± 3% and 72 ± 9% inhibitions of oligomycin-sensitive F_1F_0 ATPase activity, respectively. We observed prominent expression of δprotein kinase C in cardiac myocyte mitochondria, which was enhanced following a 4-h hypoxia exposure. In contrast, hypoxia decreased mitochondrial ζPKC levels by 85 ± 1%. Following 4 h of hypoxia, F_1F_0 ATPase activity was inhibited by 75 ± 9% and δprotein kinase C co-immunoprecipitated with the d subunit of F_1F_0 ATPase. *In vitro* incubation of protein kinase C with F_1F_0 ATPase enhanced F_1F_0 activity in the absence of protein kinase C activators and inhibited it in the presence of activators. Recombinant δprotein kinase C also inhibited F_1F_0 ATPase activity. Protein kinase C overlay assays revealed δprotein kinase C binding to the d subunit of F_1F_0 ATPase, which was modulated by diacylglycerol, phosphatidylserine, and cardiolipin. Our results suggest a novel regulation of the F_1F_0 ATPase by the δprotein kinase C isozyme.

3.1169 Transport of LDL-derived cholesterol from the NPC1 compartment to the ER involves the trans-Golgi network and the SNARE protein complex
Urano, Y. et al
*PNAS, **105(43)**, 16513-16518 (2008)*

Mammalian cells acquire cholesterol mainly from LDL. LDL enter the endosomes, allowing cholesteryl esters to be hydrolyzed by acid lipase. The hydrolyzed cholesterol (LDL-CHOL) enters the Niemann–Pick type C1 (NPC1)-containing endosomal compartment en route to various destinations. Whether the Golgi is involved in LDL-CHOL transport downstream of the NPC1 compartment has not been demonstrated. Using subcellular fractionation and immunoadsorption to enrich for specific membrane fractions, here we show that, when parental Chinese hamster ovary (CHO) cells are briefly exposed to ^{3}H-cholesteryl linoleate (CL) labeled-LDL, newly liberated ^{3}H-LDL-CHOL appears in membranes rich in trans-Golgi network (TGN) long before it becomes available for re-esterification at the endoplasmic reticulum (ER) or for efflux at the plasma membrane. In mutant cells lacking NPC1, the appearance of newly liberated ^{3}H-LDL-CHOL in the TGN-rich fractions is much reduced. We next report a reconstituted transport system that recapitulates the transport of LDL-CHOL to the TGN and to the ER. The transport system requires ATP and cytosolic factors and depends on functionality of NPC1. We demonstrate that knockdown by RNAi of 3 TGN-specific SNAREs (VAMP4, syntaxin 6, and syntaxin 16) reduces ≥50% of the LDL-CHOL transport in intact cells and in vitro. These results show that vesicular trafficking is involved in transporting a significant portion of LDL-CHOL from the NPC1-containing endosomal compartment to the TGN before its arrival at the ER.

3.1170 Importance of cholesterol-rich membrane microdomains in the interaction of the S protein of SARS-coronavirus with the cellular receptor angiotensin-converting enzyme 2
Glende, J. et al
*Virology, **381**, 215-221 (2008)*

Cholesterol present in the plasma membrane of target cells has been shown to be important for the infection by SARS-CoV. We show that cholesterol depletion by treatment with methyl-β-cyclodextrin (mβCD) affects infection by SARS-CoV to the same extent as infection by vesicular stomatitis virus-based pseudotypes containing the surface glycoprotein S of SARS-CoV (VSV-ΔG-S). Therefore, the role of cholesterol for SARS-CoV infection can be assigned to the S protein and is unaffected by other coronavirus proteins. There have been contradictory reports whether or not angiotensin-converting enzyme 2 (ACE2), the cellular receptor for SARS-CoV, is present in detergent-resistant membrane domains. We found that ACE2 of both Vero E6 and Caco-2 cells co-purifies with marker proteins of detergent-resistant membranes supporting the notion that cholesterol-rich microdomains provide a platform facilitating the efficient interaction of the S protein with the cellular receptor ACE2. To understand the involvement of cholesterol in the initial steps of the viral life cycle, we applied a cell-based binding assay with cells expressing the S protein and cells containing angiotensin-converting enzyme 2 (ACE2). Alternatively, we used a soluble S protein as interaction partner. Depletion of cholesterol from the ACE2-expressing cells reduced the binding of S-expressing cells by 50% whereas the binding of soluble S protein was not affected. This result suggests that optimal infection requires a multivalent interaction between viral attachment protein and cellular receptors.

3.1171 Membrane progestin receptors α and γ in renal epithelium
Lemale, J. et al
*Biochim. Biophys. Acta, **1783**, 2234-2240 (2008)*

Sex hormones have broader effects than regulating reproductive functions. Recent identification of membrane progestin receptors expressed in kidney prompted us to investigate their putative involvement in the renal effects of this hormone. We first focused our investigations on mPRα and γ by analyzing three parameters 1/ their distribution along the mouse nephron and their subcellular location in native kidney, 2/ the ability of progesterone to stimulate ERK pathway and/or Ca^{2+} release from internal stores in native kidney structures and 3/ the cellular localization of mPRα and its molecular determinants in heterologous expression system. We observed that 1/ mPRα expression is restricted to proximal tubules of both male and female mice whereas mPRγ exhibits a much broader expression all along the nephron except the glomerulus, 2/ mPRα and γ are not localized at the plasma membrane in native kidney, 3/ this expression does not permit either progesterone-induced ERK phosphorylation or Ca^{2+} release and 4/ in HEK transfected cells, mPRα localizes in the endoplasmic reticulum (ER) due to a C-terminal ER retention motif (− KXX). Therefore, we have characterized mPRs in kidney but their role in renal physiology remains to be elucidated.

3.1172 Early adhesion induces interaction of FAK and Fyn in lipid domains and activates raft-dependent Akt signaling in SW480 colon cancer cells
Baillat, G., Siret, C., Delamarre, E. and Luis, J.
*Biochim. Biophys. Acta, **1783**, 2323-2331 (2008)*

Integrin-dependent interaction of epithelial tumor cells with extracellular matrix (ECM) is critical for their migration, but also for hematogenous dissemination. Elevated expression and activity of Src family kinases (SFKs) in colon cancer cells is often required in the disease progression. In this work, we highlighted how focal adhesion kinase (FAK) and SFKs interacted and we analyzed how PI3K/Akt and MAPK/Erk1/2 signaling pathways were activated in early stages of colon cancer cell adhesion. During the first hour, integrin engagement triggered FAK-Y397 phosphorylation and a fraction of FAK was located in lipid rafts/caveolae domains where it interacted with Fyn. The FAK-Y861 and/or -Y925 phosphorylations led to a subsequently FAK translocation out of lipid domains. In parallel, a PI3K/Akt pathway dependent of lipid microdomain integrity was activated. In contrast, the MAPK/Erk1/2 signaling triggered by adhesion increased during at least 4 h and was independent of cholesterol disturbing. Thus, FAK/Fyn interaction in lipid microdomains and a Akt-1 activation occurred at the same time during early contact with ECM suggesting a specific signaling dependent of lipid rafts/caveolae domains.

3.1173 Night Blindness and the Mechanism of Constitutive Signaling of Mutant G90D Rhodopsin
Dizhoor, A.M. et al
*J. Neurosci., **28(45)**, 11662-11672 (2008)*

The G90D rhodopsin mutation is known to produce congenital night blindness in humans. This mutation produces a similar condition in mice, because rods of animals heterozygous (D+) or homozygous (D+/+) for this mutation have decreased dark current and sensitivity, reduced Ca^{2+}, and accelerated values of τ_{REC} and τ_D, similar to light-adapted wild-type (WT) rods. Our experiments indicate that G90D pigment activates the cascade, producing an equivalent background light of ~130 Rh* rod^{-1} for D+ and 890 Rh* rod^{-1} for D+/+. The active species of the G90D pigment could be unregenerated G90D opsin or G90D rhodopsin, either spontaneously activated (as Rh*) or in some other form. Addition of 11-*cis*-retinal in lipid vesicles, which produces regeneration of both WT and G90D opsin in intact rods and ROS membranes, had no effect on the waveform or sensitivity of dark-adapted G90D responses, indicating that the active species is not G90D opsin. The noise spectra of dark-adapted G90D and WT rods are similar, and the G90D noise variance is much less than of a WT rod exposed to background light of about the same intensity as the G90D equivalent light, indicating that Rh* is not the active species. We hypothesize that G90D rhodopsin undergoes spontaneous changes in molecular conformation which activate the transduction cascade with low gain. Our experiments provide the first indication that a mutant form of the rhodopsin molecule bound to its 11-*cis*-chromophore can stimulate the visual cascade spontaneously at a rate large enough to produce visual dysfunction.

3.1174 Lamellar Bodies of Human Epidermis: Proteomics Characterization by High Throughput Mass Spectrometry and Possible Involvement of CLIP-170 in their Trafficking/Secretion
Raymonds, A-A-. et al
*Mol. Cell. Proteomics, **7(11)**, 2151-2175 (2008)*

Lamellar bodies (LBs) are tubulovesicular secretory organelles of epithelial cells related to lysosomes. In the epidermis, they play a crucial role in permeability barrier homeostasis, secreting their contents, lipids, a variety of hydrolases, protease inhibitors, and antimicrobial peptides, in the upper keratinocyte layers. The identification of proteins transported in epidermal LBs is still far from complete, and the way their secretion is controlled unknown. In this study, we describe the first proteomics characterization by nano-LC-MS/MS of a fraction enriched in epidermal LBs. We identified 984 proteins, including proteins known or thought to be secreted by LBs. Moreover 31 proteins corresponded to lysosomal components further suggesting that LBs are a new class of secretory lysosomes. Many of the newly found proteins could play a role in the epidermal barrier and desquamation (one acid ceramidase-like protein, apolipoproteins, glycosidases, protease inhibitors, and peptidases) and in LB trafficking (*e.g.* Rab, Arf, and motor complex proteins). We focus here on CLIP-170/restin, a protein that mediates interactions between organelles and microtubules. Western blotting confirmed the presence of CLIP-170 and its known effectors IQGAP1 and Cdc42 in the LB-enriched fraction. We showed, by confocal microscopy analysis of skin cryosections, that CLIP-170 was expressed in differentiated keratinocytes, first at the periphery of the nucleus then with a granular cytoplasmic labeling evocative of LBs. It was preferentially co-localized with Cdc42 and with the known LB protein cathepsin D. CLIP-170 was also largely co-localized with Rab7. This study strongly suggests a new function for CLIP-170, its involvement together with Cdc42 and/or Rab7 in the intracellular trafficking of LBs, and provides evidence that nano-LC-MS/MS combined with monodimensional electrophoresis separation constitutes a powerful method for identifying proteins in a complex mixture such as subcellular structures.

3.1175 **P2Y1 Receptor Activation Elicits Its Partition out of Membrane Rafts and Its Rapid Internalization from Human Blood Vessels: Implications for Receptor Signaling**
Norambuena, A. et al
Mol. Pharmacol., ***74(6)***, *1666-1677 (2008)*

The nucleotide $P2Y_1$ receptor ($P2Y_1R$) is expressed in both the endothelial and vascular smooth muscle cells; however, its plasma membrane microregionalization and internalization in human tissues remain unknown. We report on the role of membrane rafts in $P2Y_1R$ signaling by using sodium carbonate or **OptiPrep** sucrose density gradients, Western blot analysis, reduction of tissue cholesterol content, and vasomotor assays of endothelium-denuded human chorionic arteries. In tissue extracts prepared either in sodium carbonate or **OptiPrep**, approximately 20 to 30% of the total $P2Y_1R$ mass consistently partitioned into raft fractions and correlated with vasomotor activity. Vessel treatment with methyl β-cyclodextrin reduced the raft partitioning of the $P2Y_1R$ and obliterated the $P2Y_1R$-mediated contractions but not the vasomotor responses elicited by either serotonin or KCl. Perfusion of chorionic artery segments with 100 nM 2-methylthio ADP or 10 nM [[(1*R*,2*R*,3*S*,4*R*,5*S*)-4-[6-amino-2-(methylthio)-9*H*-purin-9-yl] 2,3dihydroxybicyclo[3.1.0]hex-1-yl]methyl] diphosphoric acid mono ester trisodium salt (MRS 2365), a selective $P2Y_1R$ agonist, not only displaced within 4 min the $P2Y_1R$ localization out of membrane rafts but also induced its subsequent internalization. 2'-Deoxy-N^6-methyladenosine 3',5'-bisphosphate tetrasodium salt (MRS 2179), a specific $P2Y_1R$ antagonist, did not cause a similar displacement but blocked the agonist-induced exit from rafts. Neither adenosine nor uridine triphosphate displaced the $P2Y_1R$ from the membrane raft, further evidencing the pharmacodynamics of the receptor-ligand interaction. Vascular reactivity assays showed fading of the ligand-induced vasoconstrictions, a finding that correlated with the $P2Y_1R$ exit from raft domains and internalization. These results demonstrate in intact human vascular smooth muscle the association of the $P2Y_1R$ to membrane rafts, highlighting the role of this microdomain in $P2Y_1R$ signaling.

3.1176 **Hereditary Spastic Paraplegia-Associated Mutations in the NIPA1 Gene and Its Caenorhabditis elegans Homolog Trigger Neural Degeneration In Vitro and In Vivo through a Gain-of-Function Mechanism**
Zhao, J., Matthies, D.S., Botzolakis, E.J., Macdonald, R.L., Blakely, R.D. and Hedera, P.
J. Neurosci., ***28(51)***, *13938-13951 (2008)*

We studied the consequences of expression of wild-type (WT) human NIPA1 and two mutant forms of NIPA1 with known HSP-associated mutations (T45R and G106R) on cultured rat cortical neurons and using equivalent substitutions in the *Caenorhabditis elegans* NIPA1 homolog CeNIPA. WT NIPA1 localized in transfected neuronal and non-neuronal cells to the Golgi complex, a subset of synaptic vesicles, to a subset of early endosomes, and plasma cell membrane. Mutant NIPA1 accumulated in the endoplasmic reticulum (ER) triggering ER stress and features of apoptotic cell death. Flow cytometric analysis of NIPA1 surface expression demonstrated relatively intact trafficking of mutant forms and only the T45R

mutant exhibited modestly reduced patterns of surface expression without evidence for a dominant-negative effect. *In vivo* pan-neuronal expression of the WT *C. elegans* NIPA1 homolog (CeNIPA) was well tolerated, with no obvious impact on neuronal morphology or behavior. In striking contrast, expression of CeNIPA bearing HSP-associated mutations caused a progressive neural degeneration and a clear motor phenotype. Neuronal loss in these animals began at day 7 and by day 9 animals were completely paralyzed. These effects appeared to arise from activation of the apoptotic program triggered by unfolded protein response (UPR), as we observed marked modifications of motor and cellular phenotype when mutant NIPA1 was expressed in caspase (*ced-3*)- and UPR (*xbp-1*)-deficient backgrounds. We propose that HSP-associated mutations in NIPA1 lead to cellular and functional deficits through a gain-of-function mechanism supporting the ER accumulation of toxic NIPA1 proteins.

3.1177 Eosinophil granules function extracellularly as receptor-mediated secretory organelles
Neves, J.S. et al
*PNAS, **105(47)**, 18478-18483 (2008)*

Intracellular granules in several types of leukocytes contain preformed proteins whose secretions contribute to immune and inflammatory functions of leukocytes, including eosinophils, cells notably associated with asthma, allergic inflammation, and helminthic infections. Cytokines and chemokines typically elicit extracellular secretion of granule proteins by engaging receptors expressed externally on the plasma membranes of cells, including eosinophils. Eosinophil granules, in addition to being intracellular organelles, are found as intact membrane-bound structures extracellularly in tissue sites of eosinophil-associated diseases. Neither the secretory capacities of cell-free eosinophil granules nor the presence of functional cytokine and chemokine receptors on membranes of leukocyte granules have been recognized. Here, we show that granules of human eosinophils express membrane receptors for a cytokine, IFN-γ, and G protein–coupled membrane receptors for a chemokine, eotaxin, and that these receptors function by activating signal-transducing pathways within granules to elicit secretion from within granules. Capacities of intracellular granule organelles to function autonomously outside of eosinophils as independent, ligand-responsive, secretion-competent structures constitute a novel postcytolytic mechanism for regulated secretion of eosinophil granule proteins that may contribute to eosinophil-mediated inflammation and immunomodulation.

3.1178 Induction of HIV Transcription by Nef Involves Lck Activation and Protein Kinase Cθ Raft Recruitment Leading to Activation of ERK1/2 but Not NFκB
Witte, V. et al
*J. Immunol., **181**, 8425-8432 (2008)*

The Nef protein of HIV-1 is a key promoter of disease progression, owing to its dramatic yet ill-defined impact on viral replication. Previously, we have shown that Nef enhances embryonic ectodermal development Tat-mediated transcription in a manner depending on Lck and the cytoplasmic sequestration of the transcriptional repressor embryonic ectodermal development. In this study, we report that Lck is activated by Nef and targets protein kinase Cθ downstream, leading to the translocation of the kinase into membrane microdomains. Although microdomain-localized protein kinase Cθ is thought to induce the transcription factor NFκB, we unexpectedly failed to correlate Nef-induced signaling events with enhanced NFκB activity. Instead, we observed an increase in ERK MAPK activity. We conclude that Nef-mediated signaling cooperates with Nef-induced derepression and supports HIV transcription through an ERK MAPK-dependent, but NFκB-independent, pathway.

3.1179 Switch-like Control of SREBP-2 Transport Triggered by Small Changes in ER Cholesterol: A Delicate Balance
Radhakrishnan, A., Goldstein, J.L., McDonald, J.G. and Brown, M.S.
*Cell Metabolism, **8**, 512-521 (2008)*

Animal cells control their membrane lipid composition within narrow limits, but the sensing mechanisms underlying this control are largely unknown. Recent studies disclosed a protein network that controls the level of one lipid—cholesterol. This network resides in the endoplasmic reticulum (ER). A key component is Scap, a tetrameric ER membrane protein that binds cholesterol. Cholesterol binding prevents Scap from transporting SREBPs to the Golgi for activation. Using a new method to purify ER membranes from cultured cells, we show that Scap responds cooperatively to ER cholesterol levels. When ER cholesterol exceeds 5% of total ER lipids (molar basis), SREBP-2 transport is abruptly blocked. Transport resumes

when ER cholesterol falls below the 5% threshold. The 5% threshold is lowered to 3% when cells overexpress Insig-1, a Scap-binding protein. Cooperative interactions between cholesterol, Scap, and Insig create a sensitive switch that controls the cholesterol composition of cell membranes with remarkable precision.

3.1180 Mechanosensing machinery for cells under low substratum rigidity
Wei, W-C., Lin, H-H., Shen, M-R. and Tang, M-J.
*Am. J. Physiol.Cell Physiol., **295**, 1579-1589 (2008)*

Mechanical stimuli are essential during development and tumorigenesis. However, how cells sense their physical environment under low rigidity is still unknown. Here we show that low rigidity of collagen gel downregulates β_1-integrin activation, clustering, and focal adhesion kinase (FAK) Y397 phosphorylation, which is mediated by delayed raft formation. Moreover, overexpression of autoclustered β_1-integrin (V737N), but not constitutively active β_1-integrin (G429N), rescues FAKY397 phosphorylation level suppressed by low substratum rigidity. Using fluorescence resonance energy transfer to assess β_1-integrin clustering, we have found that substratum rigidity between 58 and 386 Pa triggers β_1-integrin clustering in a dose-dependent manner, which is highly dependent on actin filaments but not microtubules. Furthermore, augmentation of β_1-integrin clustering enhances the interaction between β_1-integrin, FAK, and talin. Our results indicate that contact with collagen fibrils is not sufficient for integrin activation. However, substratum rigidity is required for integrin clustering and activation. Together, our findings provide new insight into the mechanosensing machinery and the mode of action for epithelial cells in response to their physical environment under low rigidity.

3.1181 Trafficking of chlamydial antigens to the endoplasmic reticulum of infected epithelial cells
Giles, D.K. and Wyrick, P.B.
*Microbes and Infection, **10**, 1494-1503 (2008)*

Confinement of the obligate intracellular bacterium *Chlamydia trachomatis* to a membrane-bound vacuole, termed an inclusion, within infected epithelial cells neither prevents secretion of chlamydial antigens into the host cytosol nor protects chlamydiae from innate immune detection. However, the details leading to chlamydial antigen presentation are not clear. By immunoelectron microscopy of infected endometrial epithelial cells and in isolated cell secretory compartments, chlamydial major outer membrane protein (MOMP), lipopolysaccharide (LPS) and the inclusion membrane protein A (IncA) were localized to the endoplasmic reticulum (ER) and co-localized with multiple ER markers, but not with markers of the endosomes, lysosomes, Golgi nor mitochondria. Chlamydial LPS was also co-localized with CD1d in the ER. Since the chlamydial antigens, contained in everted inclusion membrane vesicles, were found within the host cell ER, these data raise additional implications for antigen processing by infected uterine epithelial cells for classical and non-classical T cell antigen presentation.

3.1182 The peroxisomal membrane protein import receptor Pex3p is directly transported to peroxisomes by a novel Pex19p- and Pex16p-dependent pathway
Matsuzaki, T. and Fujiki, Y.
*J. Cell Biol., **183(7)**, 1275-1286 (2008)*

Two distinct pathways have recently been proposed for the import of peroxisomal membrane proteins (PMPs): a Pex19p- and Pex3p-dependent class I pathway and a Pex19p- and Pex3p-independent class II pathway. We show here that Pex19p plays an essential role as the chaperone for full-length Pex3p in the cytosol. Pex19p forms a soluble complex with newly synthesized Pex3p in the cytosol and directly translocates it to peroxisomes. Knockdown of Pex19p inhibits peroxisomal targeting of newly synthesized full-length Pex3p and results in failure of the peroxisomal localization of Pex3p. Moreover, we demonstrate that Pex16p functions as the Pex3p-docking site and serves as the peroxisomal membrane receptor that is specific to the Pex3p–Pex19p complexes. Based on these novel findings, we suggest a model for the import of PMPs that provides new insights into the molecular mechanisms underlying the biogenesis of peroxisomes and its regulation involving Pex3p, Pex19p, and Pex16p.

3.1183 Dendrites of Mammalian Neurons Contain Specialized P-Body-Like Structures That Respond to Neuronal Activation
Cougot, N., Bhattacharrya, S.N., Tapia-Arancibia, L., Bordonne, R., Filipowicz, W., Bertrand, E. and Rage, F.
*J. Neurosci., **28(51)**, 13793-13804 (2008)*

Intracellular mRNA transport and local translation play a key role in neuronal physiology. Translationally repressed mRNAs are transported as a part of ribonucleoprotein (RNP) particles to distant dendritic sites, but the properties of different RNP particles and mechanisms of their repression and transport remain largely unknown. Here, we describe a new class of RNP-particles, the dendritic P-body-like structures (dlPbodies), which are present in the soma and dendrites of mammalian neurons and have both similarities and differences to P-bodies of non-neuronal cells. These structures stain positively for a number of P-body and microRNP components, a microRNA-repressed mRNA and some translational repressors. They appear more heterogeneous than P-bodies of HeLa cells, and they rarely contain the exonuclease Xrn1 but are positive for rRNA. These particles show motorized movements along dendrites and relocalize to distant sites in response to synaptic activation. Furthermore, Dcp1a is stably associated with dlP-bodies in unstimulated cells, but exchanges rapidly on neuronal activation, concomitantly with the loss of Ago2 from dlP-bodies. Thus, dlP-bodies may regulate local translation by storing repressed mRNPs in unstimulated cells, and releasing them on synaptic activation.

3.1184 **Proteomics in *Trypanosoma cruzi* – localization of novel proteins to various organelles**
Ferella, M., Nilsson, D., darban, H., Rodrigues, C., Bontempi, E.J., Docampo, R. and Andersson, B.
Proteomics, ***8(13)****, 2735-2749 (2008)*

The completion of the genome sequence of *Trypanosoma cruzi* has been followed by several studies of

protein expression, with the long-term aim to obtain a complete picture of the parasite proteome. We report a proteomic analysis of an organellar cell fraction from *T. cruzi* CL Brener epimastigotes. A total of 396 proteins were identified by LC-MS/MS. Of these, 138 were annotated as hypothetical in the genome databases and the rest could be assigned to several metabolic and biosynthetic pathways, transport, and structural functions. Comparative analysis with a whole cell proteome study resulted in the validation of the expression of 173 additional proteins. Of these, 38 proteins previously reported in other stages were not found in the only large-scale study of the total epimastigote stage proteome. A selected set of identified proteins was analyzed further to investigate gene copy number, sequence variation, transmembrane domains, and targeting signals. The genes were cloned and the proteins expressed with a c-myc epitope tag in *T. cruzi* epimastigotes. Immunofluorescence microscopy revealed the localization of these proteins in different cellular compartments such as ER, acidocalcisome, mitochondrion, and putative cytoplasmic transport or delivery vesicles. The results demonstrate that the use of enriched subcellular fractions allows the detection of *T. cruzi* proteins that are undetected by whole cell proteomic methods.

3.1185 **2-D DIGE analyses of enriched secretory lysosomes reveal heterogeneous profiles of functionally relevant proteins in leukemic and activated human NK cells**
Schmidt, H., Gelhaus, C., Nebendahl, M., Lettau, M., Wartzl, C., Kabelitz, D., Leippe, M. and Janssen, O.
Proteomics, ***8(14)****, 2911-2925 (2008)*

As part of the innate immune system, natural killer (NK) cells detect and lyse tumor and virus-infected cells without prior antigen-dependent recognition and expansion. To this end, they utilize dual-function organelles that combine properties of conventional lysosomes and exocytotic vesicles. Upon stimulation, these secretory lysosomes (SLs) release their cytotoxic molecules into the immunological synapse. In addition, several molecules associated with secretory vesicles become exposed on the plasma membrane. Recent studies often took advantage of the few established NK cell lines, for instance to analyze the exocytotic machinery associated with NK cell vesicles. NK cell lines and primary NK cells differ, however, substantially in the expression of "typical" surface receptors and their requirements to induce target cell lysis. Here, we directly compared the lysosomal compartments of different NK cell populations. We enriched SLs of two leukemic cell lines (YTS and NKL) and IL-2-expanded NK cells by subcellular fractionation and characterized their proteome by 2-D difference gel electrophoresis and MS. Although the overall protein composition of the lysosomal preparations was very similar and more than 90% of the proteins were present at comparable levels, we define a cell line-specific setup of functionally relevant proteins involved in antigen presentation and cytotoxic effector function.

3.1186 **Sub-cellular localization of membrane proteins**
Sadowski, P.G., Groen, A.J., Dupree, P. and Lilley, K.S.
Proteomics, ***8(19)****, 3991-4011 (2008)*

In eukaryotes, numerous complex sub-cellular structures exist. The majority of these are delineated by membranes. Many proteins are trafficked to these in order to be able to carry out their correct physiological function. Assigning the sub-cellular location of a protein is of paramount importance to biologists in the elucidation of its role and in the refinement of knowledge of cellular processes by tracing certain activities to specific organelles. Membrane proteins are a key set of proteins as these form part of the boundary of the organelles and represent many important functions such as transporters, receptors, and trafficking. They are, however, some of the most challenging proteins to work with due to poor solubility, a wide concentration range within the cell and inaccessibility to many of the tools employed in proteomics studies. This review focuses on membrane proteins with particular emphasis on sub-cellular localization in terms of methodologies that can be used to determine the accurate location of membrane proteins to organelles. We also discuss what is known about the membrane protein cohorts of major organelles.

3.1187 **Src-Tyrosine kinases are major agents in mitochondrial tyrosine phosphorylation**
Tibaldi, E., Brunati, A.M., Massimino, M.L., Stringaro, A., Colone, M., Agostinelli, e., Arancia, G. and Toninello, A.
J. Cell. Biochem., ***104(3)***, *840-849 (2008)*

Mitochondrial tyrosine phosphorylation is emerging as an important mechanism in regulating mitochondrial function. This article, aimed at identifying which kinases are the major agents in mitochondrial tyrosine phosphorylation, shows that this role should be attributed to Src family members. Indeed, various members of this family, for example, Fgr, Fyn, Lyn, c-Src, are constitutively present in the internal structure of mitochondria as well as Csk, a key enzyme in the regulation of the activity of this family. By means of different approaches, biochemical fractioning, Western blotting and immunogold analysis “in situ” of phosphotyrosine signaling, evidence is reported on the existence of a signal transduction pathway from plasma membrane to mitochondria, resulting in increasing Src-dependent mitochondrial tyrosine phosphorylation. The activation of Src kinases at mitochondrial level is associated with the proliferative status where several mitochondrial proteins are specifically tyrosine-phosphorylated.

3.1188 **Low substratum rigidity of collagen gel promotes ERK phosphorylation via lipid raft to augment cell migration**
Wei, W-C., Hsu, Y-C., Chiu, W-T., Wang, C-Z., Wu, C-M., Wang, Y-K., Shen, M-R. and Tang, M-J.
J. Cell. Biochem., ***103(4)***, *1111-1124 (2008)*

Previous study demonstrated that low substratum rigidity down-regulates focal adhesion proteins. In this study we found that cells cultured on collagen gel exhibited higher migration capacity than those cultured on collagen gel-coated dishes. Low rigidity of collagen gel induced delayed but persistent phosphorylation of ERK1/2. Inhibition of collagen gel-induced ERK1/2 phosphorylation by MEK inhibitors and ERK2 kinase mutant induced a rounding up of the cells and prevented collagen gel-induced cell migration. Interestingly, phosphorylated ERK1/2 induced by low rigidity was present in focal adhesion sites and the lipid raft. MβCD (Methyl-β-cyclodextrin), a lipid raft inhibitor, inhibited collagen gel-induced ERK1/2 phosphorylation, and cell migration. Overexpression of FAK C-terminal fragment (FRNK) in MDCK cells triggered ERK phosphorylation. Meanwhile, low substratum rigidity induced degradation of FAK into a 35 kDa C-terminal fragment. A calpain inhibitor that partially rescued FAK degradation also prevented low rigidity-induced ERK phosphorylation. However, MβCD did not prevent low rigidity-induced FAK degradation. Taken together, we demonstrate that the degradation product of FAK induced by collagen gel triggers activation of ERK1/2, which in turn facilitates cell spreading and migration through the lipid raft.

3.1189 *Escherichia coli* **interaction with human brain microvascular endothelial cells induces signal transducer and activator of transcription 3 association with the C-terminal domain of Ec-gp96, the outer membrane protein A receptor for invasion**
Maruvada, R., Argon, Y. and Prasadaroa, N.
Cell. Microbiol., ***10(11)***, *2326-2338 (2008)*

Our inability to develop new therapeutic strategies to prevent meningitis due to *Escherichia coli* K1 is attributed to our incomplete understanding of the pathophysiology of the disease. Previously, we demonstrated that outer membrane protein A of *E. coli* interacts with a gp96 homologue, Ec-gp96, on human brain microvascular endothelial cells (HBMEC) for invasion. However, signalling events mediated by Ec-gp96 that allow internalization of *E. coli* are incompletely understood. Here, we demonstrate that signal transducer and activator of transcription 3 (Stat3) activation and its interaction with Ec-gp96 were critical for *E. coli* invasion. The activated Stat3 was colocalized with Ec-gp96 at the actin condensation

sites, and overexpressing a dominant negative (DN) form of Stat3 in HBMEC significantly abrogated the invasion. Furthermore, overexpression of Ec-gp96Δ200, the C-terminal 214-amino-acid truncated Ec-gp96, prevented the invasion of *E. coli* in HBMEC. In contrast, lack of ATP binding by gp96 did not affect the invasion. Overexpression of DN forms of either phosphatidyl inositol-3 kinase (PI3-kinase) subunit p85 or protein kinase C-α (PKC-α) had no effect on the activation of Stat3 and its association with Ec-gp96, whereas overexpression of DN-Stat3 abolished the activation of both PI3-kinase and PKC-α. Together, our findings identified a novel interaction of Stat3 with Ec-gp96, upstream of PI3-kinase and PKC-α activation that is required for the invasion of *E. coli* into HBMEC.

3.1190 Functional interactions between anthrax toxin receptors and the WNT signalling protein LRP6
Abrami, L., Kunz, B., Deuquet, J., Bafico, A., Davidson, G and Giscoe van der Goot, F.
*Cell. Microbiol., **10(12)**, 2509-2519 (2008)*

To exert its activity, anthrax toxin must be endocytosed and its enzymatic toxic subunits delivered to the cytoplasm. It has been proposed that, in addition to the anthrax toxin receptors (ATRs), lipoprotein-receptor-related protein 6 (LRP6), known for its role in Wnt signalling, is also required for toxin endocytosis. These findings have however been challenged. We show that LRP6 can indeed form a complex with ATRs, and that this interaction plays a role both in Wnt signalling and in anthrax toxin endocytosis. We found that ATRs control the levels of LRP6 in cells, and thus the Wnt signalling capacity. RNAi against ATRs indeed led to a drastic decrease in LRP6 levels and a subsequent drop in Wnt signalling. Conversely, LRP6 plays a role in anthrax toxin endocytosis, but is not essential. We indeed found that toxin binding triggered tyrosine phosphorylation of LRP6, induced its redistribution into detergent-resistant domains, and its subsequent endocytosis. RNAis against LRP6 strongly delayed toxin endocytosis. As the physiological role of ATRs is probably to interact with the extracellular matrix, our findings raise the interesting possibility that, through the ATR–LRP6 interaction, adhesion to the extracellular matrix could locally control Wnt signalling.

3.1191 Caveolin-1 secreting LNCaP cells induce tumor growth of caveolin-1 negative LNCaP cells *in vivo*
Bartz, R., Zhou, J., Hsieh, J-T., Ying, Y., Li, W. and Liu, P.
*Int. J. Cancer, **122(3)**, 520-525 (2008)*

Caveolin-1 (Cav-1) was originally identified as a structural protein of caveolae, which is a plasma membrane domain that regulates a variety of signaling pathways involved in cell growth and migration. Here, we show that expression of Cav-1 in the Cav-1-deficient human prostate cancer cell line LNCaP both stimulates cell proliferation and promotes tumor growth in nude mice. Unexpectedly, Cav-1 expressing LNCaP ($LNCaP^{Cav\text{-}1}$) cells injected into one side of a nude mouse promoted tumor growth of Cav-1 negative LNCaP cells injected on the contralateral side of the same animal. The LNCaP tumors were positive for Cav-1, however, this signal was not caused by migrated $LNCaP^{Cav\text{-}1}$ cells, but we show that this Cav-1 was secreted by the $LNCaP^{Cav\text{-}1}$ tumors. We demonstrate that conditioned media from $LNCaP^{Cav\text{-}1}$ cells contained Cav-1 that was associated with a lipoprotein particle ranging in size from 15 to 30 nm and a density similar to high density lipoprotein particle. These results suggest that $LNCaP^{Cav\text{-}1}$ cells secreting Cav-1 particle produce an endocrine factor that stimulates tumor growth.

3.1192 A flow-cytometry method for analyzing the composition of membrane rafts
Morales-Garzia, M.G., Fournie, J-J., Morena-Altamirano, M.M.B., Rodriguez-Luna, G., Mondragon-Flores, R. and Sanchez-Garzia, F.J.
*Cytometry Part A, **73A(10),** 918-925 (2008)*

Membrane rafts are involved in a broad variety of biological processes. Their protein composition under growth factor stimulation, anti-inflammatory or proinflammatory microenvironments, or in the course of pathogenic infections still remains to be determined. However, current techniques aimed at the identification of particular proteins on membrane rafts are not devoid of pitfalls. Membrane rafts were obtained by detergent-free based differential centrifugation from Jurkat T cells and J774 macrophages. Membrane rafts were labeled with fluorochrome-labeled antibodies directed against different cell membrane molecules, and with fluorochrome-labeled cholera toxin B that targets GM1 and analyzed by flow cytometry. CD3, CD11a, and GM1 were shown to be differentially expressed on Jurkat T cell-derived membrane rafts, indicating heterogeneity in membrane rafts composition. On the other hand, it was shown in J774 cell-derived membrane rafts that most but not all CD14 is present in the GM1-containing membrane fragments, thus confirming the heterogeneity of membrane rafts composition in other cell lines. The method described here allows the fluorometric assessment of the relative expression of more than one

membrane raft component at a time, and at a single vesicle level in a fast and sensitive manner. This method seems to be a suitable approach to evaluate the molecular heterogeneity in membrane rafts composition.

3.1193 Proteomic and immunologic analyses of brain tumor exosomes
Graner, M.W., Alzate, O., Dechkovskaia, A.M., Keene, J.D., sampson, J.H., Mitchell, D.A. and Bigner, D.D.
FASEB J., ***23(5)****, 1541-1557 (2009)*

Brain tumors are horrific diseases with almost universally fatal outcomes; new therapeutics are desperately needed and will come from improved understandings of glioma biology. Exosomes are endosomally derived 30–100 nm membranous vesicles released from many cell types into the extracellular milieu; surprisingly, exosomes are virtually unstudied in neuro-oncology. These microvesicles were used as vaccines in other tumor settings, but their immunological significance is unevaluated in brain tumors. Our purpose here is to report the initial biochemical, proteomic, and immunological studies on murine brain tumor exosomes, following known procedures to isolate exosomes. Our findings show that these vesicles have biophysical characteristics and proteomic profiles similar to exosomes from other cell types but that brain tumor exosomes have unique features (*e.g.*, very basic isoelectric points, expressing the mutated tumor antigen EGFRvIII and the putatively immunosuppressive cytokine TGF-β). Administration of such exosomes into syngeneic animals produced both humoral and cellular immune responses in immunized hosts capable of rejecting subsequent tumor challenges but failed to prolong survival in established orthotopic models. Control animals received saline or cell lysate vaccines and showed no antitumor responses. Exosomes and microvesicles isolated from sera of patients with brain tumors also possess EGFR, EGFRvIII, and TGF-β. We conclude that exosomes released from brain tumor cells are biochemically/biophysically like other exosomes and have immune-modulating properties. They can escape the blood-brain barrier, with potential systemic and distal signaling and immune consequences

3.1194 Use of Bodipy-labeled sphingolipid and cholesterol analogs to examine membrane microdomains in cells
Marks, D.L., Bittman, r. and pagano, R.E.
Histochem. Cell. Biol., ***130(5)****, 819-832 (2008)*

Much evidence has accumulated to show that cellular membranes such as the plasma membrane, contain multiple “microdomains” of differing lipid and protein composition and function. These domains are sometimes enriched in cholesterol and sphingolipids and are believed to be important structures for the regulation of many biological and pathological processes. This review focuses on the use of fluorescent (Bodipy) labeled analogs of sphingolipids and cholesterol to study such domains. We discuss the similarities between the behavior of Bodipy-cholesterol and natural cholesterol in artificial bilayers and in cultured cells, and the use of Bodipy-sphingolipid analogs to visualize membrane domains in living cells based on the concentration-dependent monomer-excimer fluorescence properties of the Bodipy-fluorophore. The use of Bodipy-d-erythro-lactosylceramide is highlighted for detection of domains on the plasma membrane and endosome membranes, and the importance of the sphingolipid stereochemistry in modulating domain formation is discussed. Finally, we suggest that Bodipy-sphingolipids may be useful in future studies to examine the relationship between membrane domains at the cell surface and domains enriched in other lipids and proteins on the inner leaflet of the plasma membrane.

3.1195 A deleted prion protein that is neurotoxic in vivo is localized normally in cultured cells
Christensen, H.M. and Harris, D.A.
J. Neurochem., ***108****, 44-56 (2009)*

The prion protein (PrP) possesses sequence-specific domains that endow the molecule with neuroprotective and neurotoxic activities, and that may contribute to the pathogenesis of prion diseases. To further define critical neurotoxic determinants within PrP, we previously generated Tg([DELTA]CR) mice that express a form of PrP harboring a deletion of 21 amino acids within the central domain of the protein [Li et al., EMBO J. 26 (2007), 548]. These animals exhibit a neonatal lethal phenotype that is dose-dependently rescued by co-expression of wild-type PrP. In this study, we examined the localization and cell biological properties of the PrP([DELTA]CR) protein in cultured cells to further understand the mechanism of PrP([DELTA]CR) neurotoxicity. We found that the distribution of PrP([DELTA]CR) was identical to that of wild-type PrP in multiple cell lines of both neuronal and non-neuronal origin, and that co-expression of the two proteins did not alter the localization of either one. Both proteins were found in

lipid rafts, and both were localized to the apical surface in polarized epithelial cells. Taken together, our results suggest that PrP([DELTA]CR) toxicity is not a result of mislocalization or aggregation of the protein, and more likely stems from altered binding interactions leading to the activation of deleterious signaling pathways.

3.1196 De novo generation of a transmissible spongiform encephalopathy by mouse transgenesis
Sigurdson, C.J. et al
*PNAS, **106(1)**, 304-309 (2009)*

Most transmissible spongiform encephalopathies arise either spontaneously or by infection. Mutations of *PRNP*, which encodes the prion protein, PrP, segregate with phenotypically similar diseases. Here we report that moderate overexpression in transgenic mice of mPrP(170N,174T), a mouse PrP with two point mutations that subtly affect the structure of its globular domain, causes a fully penetrant lethal spongiform encephalopathy with cerebral PrP plaques. This genetic disease was reproduced with 100% attack rate by intracerebral inoculation of brain homogenate to *tga20* mice overexpressing WT PrP, and from the latter to WT mice, but not to PrP-deficient mice. Upon successive transmissions, the incubation periods decreased and PrP became more protease-resistant, indicating the presence of a strain barrier that was gradually overcome by repeated passaging. This shows that expression of a subtly altered prion protein, with known 3D structure, efficiently generates a prion disease.

3.1197 Human eosinophils constitutively express multiple Th1, Th2, and immunoregulatory cytokines that are secreted rapidly and differentially
Spencer, L.A., Szelaq, C.T., Perez, S.A.C., Kirschhofer, C.L., Neves, J.S., Radke, A.L and Weller, P.F.
*J. Leukoc. Biol., **85**, 117-123 (2009)*

Eosinophils are innate immune leukocytes implicated in the initiation and maintenance of type 2 immune responses, including asthma and allergy. The ability to store and rapidly secrete preformed cytokines distinguishes eosinophils from most lymphocytes, which must synthesize cytokine proteins prior to secretion and may be a factor in the apparent Th2 bias of eosinophils. Multiple studies confirm that human eosinophils from atopic or hypereosinophilic donors can secrete over 30 cytokines with a varying and often opposing immune-polarizing potential. However, it remains unclear whether all of these cytokines are constitutively preformed and available for rapid secretion from eosinophils in the circulation of healthy individuals or are restricted to eosinophils from atopic donors. Likewise, the relative concentrations of cytokines stored within eosinophils have not been studied. Here, we demonstrate that human blood eosinophils are not singularly outfitted with Th2-associated cytokines but rather, constitutively store a cache of cytokines with nominal Th1, Th2, and regulatory capacities, including IL-4, IL-13, IL-6, IL-10, IL-12, IFN-γ, and TNF-α. We demonstrate further rapid and differential release of each cytokine in response to specific stimuli. As agonists, strong Th1 and inflammatory cytokines elicited release of Th2-promoting IL-4 but not Th1-inducing IL-12. Moreover, a large quantity of IFN-γ was secreted in response to Th1, Th2, and inflammatory stimuli. Delineations of the multifarious nature of preformed eosinophil cytokines and the varied stimulus-dependent profiles of rapid cytokine secretion provide insights into the functions of human eosinophils in mediating inflammation and initiation of specific immunity.

3.1198 An Amphipathic α-Helix Controls Multiple Roles of Brome Mosaic Virus Protein 1a in RNA Replication Complex Assembly and Function
Liu, L., Westler, W.M., den Boon, J.A., Wang, X., Diaz, A., Steinberg, H.A. and Ahlquist, P.
*PloSPathogens, **5(3)**, e1000351 (2009)*

Brome mosaic virus (BMV) protein 1a has multiple key roles in viral RNA replication. 1a localizes to perinuclear endoplasmic reticulum (ER) membranes as a peripheral membrane protein, induces ER membrane invaginations in which RNA replication complexes form, and recruits and stabilizes BMV 2a polymerase ($2a^{Pol}$) and RNA replication templates at these sites to establish active replication complexes. During replication, 1a provides RNA capping, NTPase and possibly RNA helicase functions. Here we identify in BMV 1a an amphipathic α-helix, helix A, and use NMR analysis to define its structure and propensity to insert in hydrophobic membrane-mimicking micelles. We show that helix A is essential for efficient 1a–ER membrane association and normal perinuclear ER localization, and that deletion or mutation of helix A abolishes RNA replication. Strikingly, mutations in helix A give rise to two dramatically opposite 1a function phenotypes, implying that helix A acts as a molecular switch regulating the intricate balance between separable 1a functions. One class of helix A deletions and amino acid substitutions markedly inhibits 1a–membrane association and abolishes ER membrane invagination, viral

RNA template recruitment, and replication, but doubles the 1a-mediated increase in $2a^{Pol}$ accumulation. The second class of helix A mutations not only maintains efficient 1a–membrane association but also amplifies the number of 1a-induced membrane invaginations 5- to 8-fold and enhances viral RNA template recruitment, while failing to stimulate $2a^{Pol}$ accumulation. The results provide new insights into the pathways of RNA replication complex assembly and show that helix A is critical for assembly and function of the viral RNA replication complex, including its central role in targeting replication components and controlling modes of 1a action.

3.1199 Analysis of the Differential Host Cell Nuclear Proteome Induced by Attenuated and Virulent Hemorrhagic Arenavirus Infection
Bowick, G.C., Spratt, H.M., Hogg, A.E., Endsley, J.J., Wiktorowicz, J.E., Kurosky, A., Luxon, B.A., Gorenstein, D.G. and Herzog, N.K.
J. Virol., ***83(2)***, *687-700 (2009)*

Arenaviruses are important emerging pathogens and include a number of hemorrhagic fever viruses classified as NIAID category A priority pathogens and CDC potential biothreat agents. Infection of guinea pigs with the New World arenavirus *Pichindé virus* (PICV) has been used as a biosafety level 2 model for the *Lassa virus*. Despite continuing research, little is known about the molecular basis of pathogenesis, and this has hindered the design of novel antiviral therapeutics. Modulation of the host response is a potential strategy for the treatment of infectious diseases. We have previously investigated the global host response to attenuated and lethal arenavirus infections by using high-throughput immunoblotting and kinomics approaches. In this report, we describe the differential nuclear proteomes of a murine cell line induced by mock infection and infection with attenuated and lethal variants of PICV, investigated by using two-dimensional gel electrophoresis. Spot identification using tandem mass spectrometry revealed the involvement of a number of proteins that regulate inflammation via potential modulation of NF-κB activity and of several heterogeneous nuclear ribonuclear proteins. Pathway analysis revealed a potential role for transcription factor XBP-1, a transcription factor involved in major histocompatibility complex II (MHC-II) expression; differential DNA-binding activity was revealed by electrophoretic mobility shift assay, and differences in surface MHC-II expression were seen following PICV infection. These data are consistent with the results of several previous studies and highlight potential differences between transcriptional and translational regulation. This study provides a number of differentially expressed targets for further research and suggests that key events in pathogenesis may be established early in infection.

3.1200 Intracellular Signaling Mechanisms and Activities of Human Herpesvirus 8 Interleukin-6
Chen, D., Sandford, G. and Nicholas, J.
J. Virol., ***83(2)***, *722-733 (2009)*

Human herpesvirus 8 (HHV-8)-encoded viral interleukin-6 (vIL-6) has been implicated as a key factor in virus-associated neoplasia because of its proproliferative and survival effects and also in view of its angiogenic properties. A major difference between vIL-6 and human IL-6 (hIL-6) is that vIL-6, uniquely, is largely retained and can signal intracellularly. While vIL-6 is generally considered to be a lytic gene, several reports have noted its low-level expression in latently infected primary effusion lymphoma (PEL) cultures, in the absence of other lytic gene expression. Thus, intracellular autocrine signal transduction by the viral cytokine may be of particular relevance to the growth and survival of latently infected cells and to pathogenesis. Here we report that most intracellular vIL-6 is located in the endoplasmic reticulum (ER), signals via the gp130 signal transducer in this compartment, and does so independently of the gp80 α-subunit of the IL-6 receptor, required for hIL-6 signal transduction. Signaling and biological assays incorporating ER-retained vIL-6 and hIL-6 confirmed vIL-6 activity, specifically, in this compartment. Knockdown of vIL-6 expression in PEL cells led to markedly reduced cell growth in normal culture, independently of extracellular cytokines. This could be reversed by reintroduction via virus vector of exclusively ER-retained vIL-6. These data indicate that in virus biology vIL-6 may act to support the growth and survival of cells latently infected with HHV-8 in an autocrine manner via intracrine signaling and that these activities may contribute to the maintenance of latently infected cells and to virus-induced neoplasia.

3.1201 Novel N-terminal Cleavage of APP Precludes Aβ Generation in ACAT-Defective AC29 Cells
Huttunen, H.J., Puglielli, L., Ellis, B.C., MacKenzie Ingano, L.A. and Kovacs, D.M.
J. Mol. Neurosci., ***37(6)***, *6-15 (2009)*

A common pathogenic event that occurs in all forms of Alzheimer's disease is the progressive accumulation of amyloid β-peptide (Aβ) in brain regions responsible for higher cognitive functions. Inhibition of acyl-coenzyme A: cholesterol acyltransferase (ACAT), which generates intracellular cholesteryl esters from free cholesterol and fatty acids, reduces the biogenesis of the Aβ from the amyloid precursor protein (APP). Here we have used AC29 cells, defective in ACAT activity, to show that ACAT activity steers APP either toward or away from a novel proteolytic pathway that replaces both α and the amyloidogenic β cleavages of APP. This alternative pathway involves a novel cleavage of APP holoprotein at Glu281, which correlates with reduced ACAT activity and Aβ generation in AC29 cells. This sterol-dependent cleavage of APP occurs in the endosomal compartment after internalization of cell surface APP. The resulting novel C-terminal fragment APP-C470 is destined to proteasomal degradation limiting the availability of APP for the Aβ generating system. The proportion of APP molecules that are directed to the novel cleavage pathway is regulated by the ratio of free cholesterol and cholesteryl esters in cells. These results suggest that subcellular cholesterol distribution may be an important regulator of the cellular fate of APP holoprotein and that there may exist several competing proteolytic systems responsible for APP processing within the endosomal compartment.

3.1202 Analysis of Viral and Cellular Proteins in HIV-1 Reverse Transcription Complexes by Co-immunoprecipitation
Iordanskiy, S.N. and Bukrinsky, M.I.
Methods in Mol. Biol., ***485****, 121-134 (2009)*

Molecular details and temporal organization of the early (preintegration) phase of HIV life cycle remain among the least investigated and most controversial problems in the biology of HIV. To accomplish reverse transcription and intracellular transport of the viral genetic material, HIV forms multi-molecular complexes termed reverse transcription complexes (RTCs). Analysis of the kinetics of reverse transcription and nuclear import of RTCs, as well as assessment of the changes in their protein content in the course of reverse transcription and nuclear translocation is a necessary step in understanding the mechanisms of cytoplasmic maturation and nuclear import of HIV-1 RTCs. Here, we review methods that allow quantitative assessment of the dynamics of the maturation of HIV-1 RTCs and transformations of RTC protein composition associated with nuclear import of the complexes.

3.1203 Proteomics Study of the Hepatitis C Virus Replication Complex
Chang, K., Wang, T. and Luo, G.
Methods in Mol. Biol., ***510****, 185-193 (2009)*

RNA replication of HCV occurs in the multiprotein complexes associated with the endoplasmic reticular (ER) membranes. The HCV NS3 to NS5B proteins are necessary and sufficient for HCV RNA replication in the cell, but cellular proteins in the HCV replication complex (RC) have not been determined. Several methods have been used to isolate the HCV RC, including crude cell extract preparation, subcellular fractionation, and affinity purification. The components of the HCV RC can be separated by two-dimensional electrophoresis and then determined by proteolytical digestion and mass spectrometry analysis in conjunction with peptide/protein database search and immunobiochemistry and functional genomic studies.

3.1204 Proteins Associated with Immunopurified Granules from a Model Pancreatic Islet β-Cell System: Proteomic Snapshot of an Endocrine Secretory Granule
Hickey, A.J.R., Bradley, J.W.I., Skea, G.L., Middleditch, M.J., Buchanan, C.M., Phillips, A.R.J. and Cooper, G.J.S.
J. Proteome Res., ***8(1)****, 178-186 (2009)*

β-Cell granules contain proteins involved in fuel regulation, which when altered, contribute to metabolic disorders including diabetes mellitus. We analyzed proteins present in purified granules from the INS-1E β-cell model. Fifty-one component proteins were identified by LC-MS/MS including hormones, granins, protein processing components, cellular trafficking components, enzymes implicated in cellular metabolism and chaperone proteins. These findings may increase understanding of granule secretion and the processes leading to protein aggregation and β-cell death in type-2 diabetes.

3.1205 Ca^{2+} influx mechanisms in caveolae vesicles of pulmonary smooth muscle plasma membrane under inhibition of $\alpha_2\beta_1$ isozyme of Na^+/K^+-ATPase by ouabain
Ghosh, B., Kar, P., Mandal, A., Dey, K., Chakraborti, T. And Chakraborti, S.

*Life Sciences, **84**, 139-148 (2009)*

Aims
We sought to determine the mechanisms of an increase in Ca^{2+} level in caveolae vesicles in pulmonary smooth muscle plasma membrane during Na^+/K^+-ATPase inhibition by ouabain.
Main methods
The caveolae vesicles isolated by density gradient centrifugation were characterized by electron microscopic and immunologic studies and determined ouabain induced increase in Na^+ and Ca^{2+} levels in the vesicles with fluorescent probes, SBFI-AM and Fura2-AM, respectively.
Key findings
We identified the $\alpha_2\beta_1$ and $\alpha_1\beta_1$ isozymes of Na^+/K^+-ATPase in caveolae vesicles, and only the $\alpha_1\beta_1$ isozyme in noncaveolae fraction of the plasma membrane. The α_2-isoform contributes solely to the enzyme inhibition in the caveolae vesicles at 40 nM ouabain. Methylisobutylamiloride (Na^+/H^+-exchange inhibitor) and tetrodotoxin (voltage-gated Na^+-channel inhibitor) pretreatment prevented ouabain induced increase in Na^+ and Ca^{2+} levels. Ouabain induced increase in Ca^{2+} level was markedly, but not completely, inhibited by KB-R7943 (reverse-mode Na^+/Ca^{2+}-exchange inhibitor) and verapamil (L-type Ca^{2+}-channel inhibitor). However, pretreatment with tetrodotoxin in conjunction with KB-R7943 and verapamil blunted ouabain induced increase in Ca^{2+} level in the caveolae vesicles, indicating that apart from Na^+/Ca^+-exchanger and L-type Ca^{2+}-channels, "slip-mode conductance" of Na^+ channels could also be involved in this scenario.
Significance
Inhibition of α_2 isoform of Na^+/K^+-ATPase by ouabain plays a crucial role in modulating the Ca^{2+} influx regulatory components in the caveolae microdomain for marked increase in $(Ca^{2+})_i$ in the smooth muscle, which could be important for the manifestation of pulmonary hypertension.

3.1206 Moesin Regulates the Trafficking of Nascent Clathrin-coated Vesicles
Barroso-Gonzales, J., Machado, J-D., Garcia-Exposito, L. and Valenzuela-Fernandez, A.
*J. Biol. Chem., **284(4)**, 2419-2434 (2009)*

Clathrin-coated vesicles are responsible for the trafficking of several internalized biological cargos. We have observed that the endogenous F-actin-linker moesin co-distributes with constitutive components of clathrin-coated structures. Total internal reflection fluorescence microscopy studies have shown that short interference RNA of moesin enhances the lateral movement of clathrin-coated structures and provokes their abnormal clustering. The aggregation of clathrin-coated structures has also been observed in cells overexpressing N-moesin, a dominant-negative construct unable to bind to F-actin. Only overexpressed moesin constructs with an intact phosphatidylinositol 4,5-bisphosphate-binding domain co-distribute with clathrin-coated structures. Hence, this N-terminal domain is mostly responsible for moesin/clathrin-coated structure association. Biochemical endosome fractioning together with total internal reflection fluorescence microscopy comparative studies, between intact cells and plasma-membrane sheets, indicate that moesin knockdown provokes the accumulation of endocytic rab5-clathrin-coated vesicles carrying the transferrin receptor. The altered trafficking of these endocytic rab5-clathrin-coated vesicles accounts for a transferrin receptor recycling defect that reduces cell-surface expression of the transferrin receptor and increases the amount of sequestered transferrin ligand. Therefore, we propose that moesin is a clathrin-coated vesicle linker that drives cargo trafficking and acts on nascent rab5-clathrin-coated vesicles by simultaneously binding to clathrin-coated vesicle-associated phosphatidylinositol 4,5-bisphosphate and actin cytoskeleton. Hence, functional alterations of moesin may be involved in pathological disorders associated with clathrin-mediated internalization or receptor recycling.

3.1207 Kinesin Adapter JLP Links PIKfyve to Microtubule-based Endosome-to-Trans-Golgi Network Traffic of Furin
Ikonomov, O.C., Fligger, J., Sbrissa, D., Dondapati, R., Mlak, K., Deebn, R. And Shisheva, A.
*J. Biol. Chem., **284(6)**, 3750-3761 (2009)*

JIPs (c-Jun N-terminal kinase interacting proteins), which scaffold JNK/p38 MAP kinase signaling modules, also bind conventional kinesins and are implicated in microtubule-based membrane trafficking in neuronal cells. Here we have identified a novel splice variant of the *Jip4* gene product JLP_L (JNK-interacting leucine zipper protein) in yeast-two hybrid screens with the phosphoinositide kinase PIKfyve. The interaction was confirmed by pulldown and coimmunoprecipitation assays in native cells. It engages the PIKfyve cpn60_TCP1 consensus sequence and the last 75 residues of the JLP C terminus. Subpopulations of both proteins cofractionated and populated similar structures at the cell perinuclear region. Because PIKfyve is essential in endosome-to-trans-Golgi network (TGN) cargo transport, we tested

whether JLP is a PIKfyve functional partner in this trafficking pathway. Short interfering RNA (siRNA)-mediated depletion of endogenous JLP or PIKfyve profoundly delayed the microtubule-based transport of chimeric furin (Tac-furin) from endosomes to the TGN in a CHO cell line, which was rescued upon ectopic expression of siRNA-resistant JLP or PIKfyve constructs. Peptides from the contact sites in PIKfyve and JLP, or a dominant-negative PIKfyve mutant introduced into cells by ectopic expression or microinjection, induced a similar defect. Because Tac-TGN38 delivery from endosomes to the TGN, unlike that of Tac-furin, does not require intact microtubules, we monitored the effect of JLP and PIKfyve depletion or the interacting peptides administration on Tac-TGN38 trafficking. Remarkably, neither maneuver altered the Tac-TGN38 delivery to the TGN. Our data indicate that JLP interacts with PIKfyve and that both proteins and their association are required in microtubule-based, but not in microtubule-independent, endosome-to-TGN cargo transport.

3.1208 Stabilizing effects of eicosapentaenoic acid on Kv1.5 channel protein expressed in mammalian cells
Koshida, S. et al
*Eur. J. Pharmacol., **604**, 93-102 (2009)*

We investigated the effects of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) on the stability of Kv1.5 channel protein. The expression and function of Kv1.5 (Kv1.5-FLAG) in transfected African green monkey kidney fibroblast cells as well as rat atrium were estimated by immunoblotting, immunoprecipitation, immunofluorescence and patch-clamp techniques. Both EPA and DHA immediately blocked Kv1.5 channel current in a dose-dependent manner, accompanied by reduction of their phosphorylation. Chronic treatment (for 12 h) with EPA at lower concentrations (0.3–10 μM) increased the level of Kv1.5-FLAG protein as well as Kv1.5 channel current without changes in its gating kinetics, prolonging its half-life; in contrast, both EPA and DHA at higher concentrations (30–100 μM) decreased the expression of Kv1.5-FLAG. EPA at the higher concentrations also decreased mRNA of Kv1.5 and synapse-associated protein 97 expression. EPA at the lower concentrations increased Kv1.5 expression in the endoplasmic reticulum, Golgi apparatus and cell membrane. EPA-induced increase of Kv1.5 channel expression and current was abolished by pretreatment with the protein transport inhibitor brefeldin A or colchicines, and by the Kv1.5 channel blocker 4-aminopyridine. Oral administration of EPA (30 mg/kg) increased the level of endogenous Kv1.5 in rat atria. These results indicate that chronic treatment with EPA at lower concentrations stabilizes Kv1.5 channel protein in the endoplasmic reticulum and Golgi apparatus thereby enhancing the Kv1.5 channel current on the cell membrane.

3.1209 The N-terminal half of the receptor domain of botulinum neurotoxin A binds to microdomains of the plasma membrane
Muraro, L., Tosatto, S., Motterlini, L., Rosetto, O. and Montecucco, C.
*Biochem. Biophys. Res. Comm., **380**, 76-80 (2009)*

Botulinum neurotoxin type A (BoNT/A) is largely employed in human therapy because of its specific inhibition of peripheral cholinergic nerve terminals. BoNT/A binds to them rapidly and with high specificity via its receptor binding domain termed HC. Recent evidence indicate that BoNT/A interacts specifically with polysialogangliosides and with a luminal loop of the synaptic vesicle protein SV2 via the C-terminal half of HC.
Here we show that the N-terminal half of HC binds to sphingomyelin-enriched membrane microdomains and that it has a defined interaction with phosphatidylinositol phosphates (PIP). We have identified a PIP binding site in this half of HC and we show how this interaction could predispose BoNT/A for membrane insertion, which is the step subsequent to binding, in the four-steps route leading BoNT/A inside nerve terminals.

3.1210 Biochemical and proteomic approaches for the study of membrane microdomains
Zheng, Y.Z. and Foster, L.J.
*J. Proteomics, **72**, 12-22 (2009)*

Many cellular signaling and communication events take place at the plasma membrane and thus the characterization of the plasma membrane proteome has been a hot research area in the hopes of learning more about these processes. Membrane microdomains are large protein and lipid complexes found on the cell surface membrane, able to concentrate or recruit signaling molecules or factors. The first step of any organelle proteomics study is to get a pure and enriched protein sample yet this has always been problematic in membrane proteomics as it is virtually impossible to purify a specific membrane type to homogeneity. In this review, we summarize the biochemical and proteomic approaches that have been

used recently in the isolation and identification of several membrane microdomains and non-typical membrane proteins.

3.1211 Recruitment of protein phosphatase 2A to dorsal ruffles by platelet-derived growth factor in smooth muscle cells: Dephosphorylation of Hsp27
Berrou, E and Brykaert, M.
*Exp. Cell Res., **315**, 836-848 (2009)*

In this study, we investigated the mechanism underlying Hsp27 dephosphorylation in smooth muscle cells. We found that protein phosphatase 2A (PP2A) dephosphorylates Hsp27. In addition, Hsp27 dephosphorylation was regulated by membrane cholesterol content. We showed that PDGF induced a three-fold increase in the proportion of PP2A activity regulated by cholesterol in the Triton-insoluble fraction of cell lysates. Moreover, cholesterol depletion decreased the amount of PP2A recovered in Triton-insoluble fraction. Thus, PDGF might regulate a small pool of PP2A associated with lipid rafts. Isolation of detergent-resistant membrane fragments by Optiprep-gradient density indicated that this pool of PP2A was not associated with caveolae, but was recovered in a higher density fraction (DRM-H) with ganglioside GM1, α-actinin, Hsp27 and p34, a component of Arp2/3 complex. These proteins were also present in dorsal ruffles containing GM1 but not caveolin-1. Phosphorylated Hsp27 levels detected in dorsal ruffles were variable. Cholesterol depletion, which inhibits dorsal ruffle formation, decreased PP2A levels and increased the Hsp27-P to Hsp27 ratio in DRM-H. These findings suggest that Hsp27 is dephosphorylated by PP2A in dorsal ruffles, in non-caveolar lipid raft microdomains. However, similarly to p34, non-phosphorylated Hsp27 is associated to non-raft membrane domains at the leading edge of lamellipodia.

3.1212 HTLV-1 Tax Is a Critical Lipid Raft Modulator That Hijacks IκB Kinases to the Microdomains for Persistent Activation of NF-κB
Huang, J., Ren, T., Guan, H., Jiang, Y. And Cheng, H.
*J.Biol. Chem., **284(10)**, 6208-6217 (2009)*

Upon T cell activation, IκB kinases (IKKs) are transiently recruited to the plasma membrane-associated lipid raft microdomains for activation of NF-κB in promoting T cell proliferation. Retroviral Tax proteins from human T cell leukemia virus type 1 and type 2 (HTLV-1 and -2) are capable of activating IKK, yet only HTLV-1 infection causes T cell leukemia, which correlates with persistent activation of NF-κB induced by Tax1. Here, we show that the Tax proteins exhibit differential modes of IKK activation. The subunits of IKK are constitutively present in lipid rafts in activated forms in HTLV-1-infected T cells that express Tax. Disruption of lipid rafts impairs IκB kinase activation by Tax1. We also show that the cytoplasmic Tax1 protein persistently resides in the Golgi-associated lipid raft microdomains. Tax1 directs lipid raft translocation of IKK through selective interaction with IKKγ and accordingly, depletion of IKKγ impairs Tax1-directed lipid raft recruitment of IKKα and IKKβ. In contrast, Tax2 activates NF-κB in a manner independent of lipid raft recruitment of IKK. These findings indicate that Tax1 actively recruits IKK to the lipid raft microdomains for persistent activation of NF-κB, thereby contributing to HTLV-1 oncogenesis.

3.1213 Proteomic profiling of secretory granules of different T cell subpopulations
Schmidt, H., Gelhaus, C., Nebendahl, M., Leippe, M. and Janssen, O.
*Cell Communication and Signaling, **7 (Suppl 1),** A85 (2009)*

In cytotoxic T lymphocytes and Natural Killer (NK) cells, effector molecules including granzymes, perforin, granulysin and FasL are stored in specialized granules termed secretory lysosomes (SL). These vesicles represent dual-functional organelles that obviously combine degradative and exocytotic properties [1]. We previously established an enrichment protocol to define the proteome of SL from NK cells. We found that the protein content of SL very much depends on the function of a given cell type or clone, best reflected by crucial differences in functionally relevant proteins in transformed NK cell lines [2].
In order to compare the lysosomal content of different T cell subpopulations, we enriched SL from alpha/beta (CD4 or CD8) and gamma/delta (Vdelta 1 or Vdelta2) T cell lines and clones. To this end, the T cell lysates were separated by density gradient centrifugation on Iodixanol gradients. As described before, for the differential proteome analysis we focused on the fraction that contained most FasL, Lamp1 and

Lamp3 (as specific SL or general lysosomal markers) and compared the isolated lysosomal fractions by 2D-DIGE. We found that the protein content of SL of *in vitro* expanded CD4 and CD8 cells as well as Vdelta1 and Vdelta 2 cells is more similar than for example gamma/delta cells compared to alpha/beta cells. A detailed MALDI-based profile of individual SL proteomes based on more than 1000 picked spots from several DIGE experiments will be presented with a focus on the functionally relevant proteins mentioned above. The observed differences might reveal new aspects of population-specific dynamics of activation/maturation and effector function in the T cell compartment.

3.1214 The Comprehensive Native Interactome of a Fully Functional Tagged Prion Protein
Rutishauer, D., Mertz, K.D., Moos, R., Brunner, E., Rülicke, T., Calella, A.M. and Aguzzi, A.
PloSOne, ***4(2)***, *e446 (2009)*

The enumeration of the interaction partners of the cellular prion protein, PrP^{C}, may help clarifying its elusive molecular function. Here we added a carboxy proximal myc epitope tag to PrP^{C}. When expressed in transgenic mice, PrP_{myc} carried a GPI anchor, was targeted to lipid rafts, and was glycosylated similarly to PrP^{C}. PrP_{myc} antagonized the toxicity of truncated PrP, restored prion infectibility of PrP^{C}-deficient mice, and was physically incorporated into PrP^{Sc} aggregates, indicating that it possessed all functional characteristics of genuine PrP^{C}. We then immunopurified myc epitope-containing protein complexes from PrP_{myc} transgenic mouse brains. Gentle differential elution with epitope-mimetic decapeptides, or a scrambled version thereof, yielded 96 specifically released proteins. Quantitative mass spectrometry with isotope-coded tags identified seven proteins which co-eluted equimolarly with PrP^{C} and may represent component of a multiprotein complex. Selected PrP^{C} interactors were validated using independent methods. Several of these proteins appear to exert functions in axomyelinic maintenance.

3.1215 Depletion of Kinesin 5B Affects Lysosomal Distribution and Stability and Induces Peri-Nuclear Accumulation of Autophagosomes in Cancer Cells
Cardoso, C.M.P., Groth-Pedersen, L., Høyer-Hansen, M., Kirkegaard, T., Corcelle, E., Andersen, J.S.-, Jäättelä, M. and Nylandsted, J.
PloSOne, ***4(2)***, *e4424 (2009)*

Background
Enhanced lysosomal trafficking is associated with metastatic cancer. In an attempt to discover cancer relevant lysosomal motor proteins, we compared the lysosomal proteomes from parental MCF-7 breast cancer cells with those from highly invasive MCF-7 cells that express an active form of the ErbB2 (ΔN-ErbB2).
Methodology/Principal Findings
Mass spectrometry analysis identified kinesin heavy chain protein KIF5B as the only microtubule motor associated with the lysosomes in MCF-7 cells, and ectopic ΔN-ErbB2 enhanced its lysosomal association. KIF5B associated with lysosomes also in HeLa cervix carcinoma cells as analyzed by subcellular fractionation. The depletion of KIF5B triggered peripheral aggregations of lysosomes followed by lysosomal destabilization, and cell death in HeLa cells. Lysosomal exocytosis in response to plasma membrane damage as well as fluid phase endocytosis functioned, however, normally in these cells. Both HeLa and MCF-7 cells appeared to express similar levels of the KIF5B isoform but the death phenotype was weaker in KIF5B-depleted MCF-7 cells. Surprisingly, KIF5B depletion inhibited the rapamycin-induced accumulation of autophagosomes in MCF-7 cells. In KIF5B-depleted cells the autophagosomes formed and accumulated in the close proximity to the Golgi apparatus, whereas in the control cells they appeared uniformly distributed in the cytoplasm.
Conclusions/Significance
Our data identify KIF5B as a cancer relevant lysosomal motor protein with additional functions in autophagosome formation.

3.1216 Passage through the Golgi is necessary for Shiga toxin B subunit to reach the endoplasmic reticulum
McKinzie, J., Johannes, L., Taguchi, T. and Sheff, D.
FEBS J., ***276***, *1581-1595 (2009)*

Both Shiga holotoxin and the isolated B subunit, navigate a retrograde pathway from the plasma membrane to the endoplasmic reticulum (ER) of mammalian cells to deliver catalytic A subunits into the cytosol. This route passes through early/recycling endosomes and then through the Golgi. Although passage through the endosomes takes only 30 min, passage through the Golgi is much slower, taking hours. This suggests that Golgi passage is a key step in retrograde traffic. However, there is no empirical data demonstrating that Golgi passage is required for the toxins to enter the ER. In fact, an alternate pathway bypassing the Golgi is utilized by SV40 virus. Here we find that blocking Shiga toxin B access to the entire Golgi with AlF_4^- treatment, temperature block or subcellular surgery prevented Shiga toxin B from reaching the ER. This suggests that there is no direct endosome to ER route available for retrograde traffic. Curiously, when Shiga toxin B was trapped in endosomes, it entered the cytosol directly from the endosomal compartment. Our results suggest that trafficking through the Golgi apparatus is required for Shiga toxin B to reach the ER and that diversion into the Golgi may prevent toxin escape from endosomes into the cytosol.

3.1217 Channel-forming activities of peroxisomal membrane proteins from the yeast *Saccharomyces cerevisiae*

Grunau, S., Mindthoff, S., Rottensteiner, H., Sormuen, R.T., Hitunen, J.K., Erdmann, R. And Antonenkov, V.D.

*FEBS J., **276**, 1698-1708 (2009)*

Highly-purified peroxisomes from the yeast *Saccharomyces cerevisiae* grown on oleic acid were investigated for the presence of channel (pore)-forming proteins in the membrane of these organelles. Solubilized membrane proteins were reconstituted in planar lipid bilayers and their pore-forming activity was studied by means of multiple-channel monitoring or single-channel analysis. Two abundant pore-forming activities were detected with an average conductance of 0.2 and 0.6 nS in 1.0 M KCl, respectively. The high-conductance pore (0.6 nS in 1.0 M KCl) is slightly selective to cations (P_{K+}/P_{Cl-} ~ 1.3) and showed an unusual flickering at elevated (> ±40 mV) holding potentials directed upward relative to the open state of the channel. The data obtained for the properties of the low-conductance pore (0.2 nS in 1.0 M KCl) support the notion that the high-conductance channel represents a cluster of two low-conductance pores. The results lead to conclusion that the yeast peroxisomes contain membrane pore-forming proteins that may aid the transfer of small solutes between the peroxisomal lumen and cytoplasm.

3.1218 Pseudomonas aeruginosa vesicles associate with and are internalized by human lung epithelial cells

Bauman, S.J. and Kuehn, M.J.

*BMC Microbiol., **9**, 26-37 (2009)*

Background

Pseudomonas aeruginosa is the major pathogen associated with chronic and ultimately fatal lung infections in patients with cystic fibrosis (CF). To investigate how *P. aeruginosa*-derived vesicles may contribute to lung disease, we explored their ability to associate with human lung cells.

Results

Purified vesicles associated with lung cells and were internalized in a time- and dose-dependent manner. Vesicles from a CF isolate exhibited a 3- to 4-fold greater association with lung cells than vesicles from the lab strain PAO1. Vesicle internalization was temperature-dependent and was inhibited by hypertonic sucrose and cyclodextrins. Surface-bound vesicles rarely colocalized with clathrin. Internalized vesicles colocalized with the endoplasmic reticulum (ER) marker, TRAPα, as well as with ER-localized pools of cholera toxin and transferrin. CF isolates of *P. aeruginosa* abundantly secrete PaAP (PA2939), an aminopeptidase that associates with the surface of vesicles. Vesicles from a PaAP knockout strain exhibited a 40% decrease in cell association. Likewise, vesicles from PAO1 overexpressing PaAP displayed a significant increase in cell association.

Conclusion

These data reveal that PaAP promotes the association of vesicles with lung cells. Taken together, these results suggest that *P. aeruginosa* vesicles can interact with and be internalized by lung epithelial cells and contribute to the inflammatory response during infection.

3.1219 HIV entry in macrophages is dependent on intact lipid rafts

Carter, G.C., Bernstone, L., Sangani, D., Bee, W.J., Harder, T. and James, W.

*Virology, **386**, 192-202 (2009)*

Macrophages are an important natural target cell for HIV-1, but previous studies of virus entry into these cells are limited, and the involvement of membrane cholesterol and lipid rafts is unknown. Cholesterol disruption of macrophage membranes using four pharmacological agents acting by different mechanisms: methyl-β cyclodextrin, nystatin, filipin complex and Lovastatin, all significantly inhibited productive HIV entry and reverse transcription. The inhibitory effects of these drugs resulted in decreased virus release from infected cells, and could be substantially reversed by the addition of water-soluble cholesterol. The virus bound equally to cholesterol-disrupted cells even though HIV receptor expression levels were significantly reduced. Macrophage CD4 and CCR5 were found to partition with the detergent-resistant membranes with a typical raft-associating protein flotillin-1. HIV particles were observed co-localising with a marker of lipid rafts (CTB-FITC) early post infection. These data suggest that macrophage membrane cholesterol is essential for HIV entry, and implicate lipid raft involvement.

3.1220 Biochemical and functional characterization of the Ror2/BRIb receptor complex
Sammar, M., Sieber, C. and Knaus, P.
Biochem. Biophys. Res. Comm., ***381***, *1-6 (2009)*

Ror2 belongs to the Ror family of receptor tyrosine kinases. Two distinct human disorders result from mutations in Ror2 suggesting a role in cartilage formation, chondrocyte differentiation, and joint formation. We have previously demonstrated functional and physical association of Ror2 with the BMP receptor type Ib (BRIb). The interaction site was mapped to the extracellular CRD domain of Ror2. Here we show specific association with and transphosphorylation by BRIb, but not BMP receptors Ia or II. This association is independent of *N*-glycosylation, excluding the possibility that the interaction is mediated by carbohydrate moieties present in the CRD region of Ror2. The Ror2/BRIb complex proved very stable under high ionic and reducing conditions, yet it appeared sensitive to SDS-treatment. Besides we provide evidence that the Ror2/BRIb complex forms in distinct microdomains at the plasma membrane (DRMs), indicating that Ror2 may interfere with BMP signaling complexes within these membrane domains.

3.1221 Transmembrane Form Agrin-induced Process Formation Requires Lipid Rafts and the Activation of Fyn and MAPK
Ramseger, R., White, R. and Kröger, S.
J. Biol. Chem., ***284(12***, *7697-7705 (2009)*

Overexpression or clustering of the transmembrane form of the extracellular matrix heparan sulfate proteoglycan agrin (TM-agrin) induces the formation of highly dynamic filopodia-like processes on axons and dendrites from central and peripheral nervous system-derived neurons. Here we show that the formation of these processes is paralleled by a partitioning of TM-agrin into lipid rafts, that lipid rafts and transmembrane-agrin colocalize on the processes, that extraction of lipid rafts with methyl-β-cyclodextrin leads to a dose-dependent reduction of process formation, that inhibition of lipid raft synthesis prevents process formation, and that the continuous presence of lipid rafts is required for the maintenance of the processes. Association of TM-agrin with lipid rafts results in the phosphorylation and activation of the Src family kinase Fyn and subsequently in the phosphorylation and activation of MAPK. Inhibition of Fyn or MAPK activation inhibits process formation. These results demonstrate that the formation of filopodia-like processes by TM-agrin is the result of the activation of a complex intracellular signaling cascade, supporting the hypothesis that TM-agrin is a receptor or coreceptor on neurons.

3.1222 Contribution of PIP-5 kinase Iα to raft-based FcγRIIA signaling
Symanska, E., Korzeniowski, M., Raynal, P., Sobota, A. and Kwiatkowska, K.
Exp. Cell Res., ***315***, *981-995 (2009)*

Receptor FcγIIA (FcγRIIA) associates with plasma membrane rafts upon activation to trigger signaling cascades leading to actin polymerization. We examined whether compartmentalization of $PI(4,5)P_2$ and $PI(4,5)P_2$-synthesizing PIP5-kinase Iα to rafts contributes to FcγRIIA signaling. A fraction of PIP5-kinase Iα was detected in raft-originating detergent-resistant membranes (DRM) isolated from U937 monocytes and other cells. The DRM of U937 monocytes contained also a major fraction of $PI(4,5)P_2$. PIP5-kinase Iα bound $PI(4,5)P_2$, and depletion of the lipid displaced PIP5-kinase Iα from the DRM. Activation of FcγRIIA in BHK transfectants led to recruitment of the kinase to the plasma membrane and enrichment of DRM in $PI(4,5)P_2$. Immunofluorescence studies revealed that in resting cells the kinase was associated with the

plasma membrane, cytoplasmic vesicles and the nucleus. After FcγRIIA activation, PIP5-kinase Iα and $PI(4,5)P_2$ co-localized transiently with the activated receptor at distinct cellular locations. Immunoelectron microscopy studies revealed that PIP5-kinase Iα and $PI(4,5)P_2$ were present at the edges of electron-dense assemblies containing activated FcγRIIA in their core. The data suggest that activation of FcγRIIA leads to membrane rafts coalescing into signaling platforms containing PIP5-kinase Iα and $PI(4,5)P_2$.

3.1223 The tyrosine phosphatase SHP-2 controls urokinase-dependent signaling and functions in human vascular smooth muscle cells

Kiyan, J., Haller, H. and Dumler, I.
*Exp. Cell Res., **315**, 1029-1039 (2009)*

The urokinase (uPA)/urokinase receptor (uPAR) multifunctional system is an important mediator of functional behaviour of human vascular smooth muscle cells (VSMC). uPAR associates with platelet-derived growth factor receptor β (PDGFR-β), which serves as a transmembrane adaptor for uPAR in VSMC, to transduce intracellular signaling and initiate functional changes. The precise and rapid propagation of these signaling cascades demands both strict and flexible regulatory mechanisms that remain unexplored. We provide evidence that the tyrosine phosphatase SHP-2 mediates these processes. uPA regulated SHP-2 phosphorylation, catalytic activity, and its co-localization and association with the PDGFR-β. Active PDGFR-β was required for the uPA-induced SHP-2 phosphorylation. uPAR-directed STAT1 pathway was disturbed in cells expressing SHP-2 inactive mutant. Both, cell proliferation and migration were impaired in VSMC with downregulated SHP-2. Elucidating the underlying mechanisms, we found that uPA induced SHP-2 recruitment to lipid rafts. Disruption of rafts abolished uPA-related control of SHP-2 phosphorylation, its association with PDGFR-β and finally the VSMC functional responses. Our results demonstrate that SHP-2 plays an important role in uPA-directed signaling and functional control of human VSMC and suggest that this phosphatase might contribute to the pathogenesis of the uPA-related vascular remodeling.

3.1224 Flagellar membrane localization via association with lipid rafts

Tyler, K.M., Fridberg, A., Toriello, K.M., Olson, C.L., Cieslak, J.A., Hazlett, T.L. and Engman, D.M.
*J. Cell. Sci., **122**, 859-866 (2009)*

The eukaryotic flagellar membrane has a distinct composition from other domains of the plasmalemma. Our work shows that the specialized composition of the trypanosome flagellar membrane reflects increased concentrations of sterols and saturated fatty acids, correlating with direct observation of high liquid order by laurdan fluorescence microscopy. These findings indicate that the trypanosome flagellar membrane possesses high concentrations of lipid rafts: discrete regions of lateral heterogeneity in plasma membranes that serve to sequester and organize specialized protein complexes. Consistent with this, a dually acylated Ca^{2+} sensor that is concentrated in the flagellum is found in detergent-resistant membranes and mislocalizes if the lipid rafts are disrupted. Detergent-extracted cells have discrete membrane patches localized on the surface of the flagellar axoneme, suggestive of intraflagellar transport particles. Together, these results provide biophysical and biochemical evidence to indicate that lipid rafts are enriched in the trypanosome flagellar membrane, providing a unique mechanism for flagellar protein localization and illustrating a novel means by which specialized cellular functions may be partitioned to discrete membrane domains.

3.1225 Identification of a palmitoyl acyltransferase required for protein sorting to the flagellar membrane

Emmer, B.T., Souther, C., Tooriello, K.M., Olson, C.L., Epting, C.L. and Engman, D.M.
*J. Cell Sci., **122**, 867-874 (2009)*

Protein palmitoylation has diverse effects in regulating protein membrane affinity, localization, binding partner interactions, turnover and function. Here, we show that palmitoylation also contributes to the sorting of proteins to the eukaryotic flagellum. African trypanosomes are protozoan pathogens that express a family of unique Ca^{2+}-binding proteins, the calflagins, which undergo N-terminal myristoylation and palmitoylation. The localization of calflagins depends on their acylation status. Myristoylation alone is sufficient for membrane association, but, in the absence of palmitoylation, the calflagins localize to the pellicular (cell body) membrane. Palmitoylation, which is mediated by a specific palmitoyl acyltransferase, is then required for subsequent trafficking of calflagin to the flagellar membrane. Coincident with the redistribution of calflagin from the pellicular to the flagellar membrane is their association with lipid rafts,

which are highly enriched in the flagellar membrane. Screening of candidate palmitoyl acyltranferases identified a single enzyme, TbPAT7, that is necessary for calflagin palmitoylation and flagellar membrane targeting. Our results implicate protein palmitoylation in flagellar trafficking, and demonstrate the conservation and specificity of palmitoyl acyltransferase activity by DHHC-CRD proteins across kingdoms.

3.1226 Can we generate new hypotheses about Dent's disease from gene analysis of a mouse model?
Guggino, S.E.
Exp. Physiol., ***94(2)***, *191-196 (2009)*

In humans, Dent's disease, an X-linked renal tubular disorder, is characterized by low molecular weight proteinuria, aminoaciduria, glycosuria, hyperphosphaturia, hypercalciuria, nephrolithiasis, progressive renal failure and sometimes rickets or osteomalacia. The aetiology of X-linked Dent's disease is established to be caused by mutations of the *CLCN5* gene. The protein product of this gene is the voltage-gated chloride–proton exchanger CLC-5. Previous studies by the Johns Hopkins group (Guggino) and the Hamburg group (Jentsch) have established that the *Clcn5* knockout mouse recapitulates the renal attributes of Dent's disease. In order to understand the changes in kidney function that accompany the knockout of the *Clcn5* gene, we examined gene expression profiles from dissected proximal segment 1 (S1) and segment 2 (S2) tubules of mouse kidneys. Overall, 725 genes are expressed differentially in the proximal tubules of the Dent *Clcn5* knockout mouse model compared with those of control wild-type mice. A major finding is the change in the cholesterol synthesis pathway. Some interesting changes also occur in genes encoding transport proteins. One of these transport proteins, the sodium bile cotransporter gene, *Slc10a2*, has transcripts increased by 17-fold in the *Clcn5* knockout mouse. The Clc-3 protein encoded by *Clcn3*, a chloride–proton exchanger related to Clc-5, has a 1.9-fold increase in transcripts. The Npt2c protein, a proximal tubule sodium phosphate cotransporter encoded by *Slc34a3*, has a 0.6-fold decrease in the number of transcripts. The sodium–proton exchanger-like protein, Nhe10/sperm, encoded by *Slc9a10*, has a 0.5-fold decrease in transcript number. These genes are discussed with regard to the possible physiological outcomes of their transcript or protein changes.

3.1227 The Ubiquitin Ligase c-Cbl Down-Regulates FcγRIIa Activation in Human Neutrophils
Marois, L., Vaillancourt, M., Marois, S., Proulx, S., Pare, G., Rollet-Labelle, E. and Naccache, P.H.
J. Immunol., ***182***, *2374-2384 (2009)*

Little is known about the mechanisms that arrest FcγRIIa signaling in human neutrophils once engaged by immune complexes or opsonized pathogens. In our previous studies, we observed a loss of immunoreactivity of Abs directed against FcγRIIa following its cross-linking. In this study, we report on the mechanisms involved in this event. A stimulated internalization of FcγRIIa leading to the down-regulation of its surface expression was observed by flow cytometry and confocal microscopy. Immunoprecipitation of the receptor showed that FcγRIIa is ubiquitinated after stimulation. MG132 and clasto-lactacystin β-lactone inhibited the loss of immunoreactivity of FcγRIIa, suggesting that this receptor was down-regulated via the proteasomal pathway. The E3 ubiquitin ligase c-Cbl was found to translocate from the cytosol to the plasma membrane following receptor cross-linking. Furthermore, c-Cbl was recruited to the same subset of high-density, detergent-resistant membrane fractions as stimulated FcγRIIa itself. Silencing the expression of c-Cbl by small interfering RNA decreased FcγRIIa ubiquitination and prevented its degradation without affecting the internalisation process. It also prolonged the stimulation of the tyrosine phosphorylation response to the cross-linking of the receptor. We conclude that c-Cbl mediates the ubiquitination of stimulated FcγRIIa and thereby contributes to the termination of FcγRIIa signaling via its proteasomal degradation, thus leading to the down-regulation of neutrophil signalisation and function (phagocytosis) through this receptor.

3.1228 Activation of a nuclear-localized SIPK in tobacco cells challenged by cryptogein, an elicitor of plant defence reactions
Dahan, J., Pichereaux, C., Rossignol, M., Blanc, S., Wendenhenne, D., Pugin, A. and Bourque, S.
Biochem. J., ***418***, *191-200 (2009)*

When a plant cell is challenged by a well-defined stimulus, complex signal transduction pathways are activated to promote the modulation of specific sets of genes and eventually to develop adaptive responses. In this context, protein phosphorylation plays a fundamental role through the activation of multiple protein kinase families. Although the involvement of protein kinases at the plasma membrane and cytosolic levels

are now well-documented, their nuclear counterparts are still poorly investigated. In the field of plant defence reactions, no known study has yet reported the activation of a nuclear protein kinase and/or its nuclear activity in plant cells, although some protein kinases, e.g. MAPK (mitogen-activated protein kinase), are known to be translocated into the nucleus. In the present study, we investigated the ability of cryptogein, a proteinaceous elicitor of tobacco defence reactions, to induce different nuclear protein kinase activities. We found that at least four nuclear protein kinases are activated in response to cryptogein treatment in a time-dependent manner, some of them exhibiting Ca^{2+}-dependent activity. The present study focused on one 47 kDa protein kinase with a Ca^{2+}-independent activity, closely related to the MAPK family. After purification and microsequencing, this protein kinase was formally identified as SIPK (salicyclic acid-induced protein kinase), a biotic and abiotic stress-activated MAPK of tobacco. We also showed that cytosolic activation of SIPK is not sufficient to promote a nuclear SIPK activity, the latter being correlated with cell death. In that way, the present study provides evidence of a functional nuclear MAPK activity involved in response to an elicitor treatment.

3.1229 **Quantification of plasmid DNA copies in the nucleus after lipoplex and polyplex transfection**
Cohen, R.N., van der Aa, M.A.E.M., Macaraeg, N., Lee, A.P. and Szoka Jr., F.C.
J. Controlled Release, ***135***, *166-174 (2009)*

Nuclear uptake of plasmid DNA is one of the many cellular barriers that limit the efficiency of non-viral gene delivery systems. We have determined the number of plasmids that reach the nucleus of a transfected cell using an internally standardized quantitative PCR (qPCR) assay. We isolated nuclei using two different protocols: a density gradient technique and a detergent-based method. The density gradient procedure yielded nuclei with substantially less adhering plasmids on the outside of the nuclei. Using the density gradient protocol we determined that cells transfected with Lipofectamine™ lipoplexes or polyethylenimine polyplexes contained between 75 and 50,000 plasmids/nucleus, depending on the applied plasmid dose. Any increase above 3000 plasmids/nucleus resulted in only marginal increases in transgene expression. Furthermore, lipoplex-delivered plasmids were more efficiently expressed, on the basis of protein expression per plasmid number in the nucleus, than polyplex-delivered plasmids. This indicates that polymer may remain bound to some plasmids in the nucleus. Lastly, by sorting transfected cells into high- and low-expressing sub-populations, we observe that a sub-population of cells contain 3× greater plasmids/nucleus but express nearly 100× more transgene than other cells within a single transfection reaction. Taken together these results suggest the importance of considering the processes downstream from nuclear entry for strategies to improve the efficiency of gene transfer reagents.

Corrigendum to "Quantification of plasmid DNA copies in the nucleus after lipoplex and polyplex transfection"
Cohen, R.N., van der Aa, M.A.E.M., Macaraeg, N., Lee, A.P. and Szoka Jr., F.C.

Kume, H., Konishis, Y., Murayama, K.S., kametani, F. and Araki, W.
Neuropathol. and Appl. Neurobiol., ***35***, *178-188 (2009)*

Aims:: Reticulon 3 (RTN3), a member of the reticulon family of proteins, interacts with the β-secretase, β-site amyloid precursor protein-cleaving enzyme 1 (BACE1), and inhibits its activity to produce β-amyloid protein. The aim of the present study was to clarify the biological role of RTN3 in the brain and its potential involvement in the neuropathology of Alzheimer's disease (AD).
Methods:: We performed immunohistochemical and biochemical analyses using a specific antibody against RTN3 to investigate the expression and subcellular localization of RTN3 in control and AD brain tissue samples.
Results:: Western blot analysis revealed no significant differences in the RTN3 levels between control and AD brains. Immunohistochemical staining showed that RTN3 immunoreactivity was predominantly localized in pyramidal neurones of the cerebral cortex. The patterns of RTN3 immunostaining were similar in control and AD cerebral cortices, and senile plaques were generally negative for RTN3. Biochemical

subcellular fractionation disclosed that RTN3 colocalized with BACE1 in various fractions, including the endoplasmic reticulum and the Golgi apparatus. Double-immunofluorescence staining additionally indicated that RTN3 was localized in both endoplasmic reticulum and Golgi compartments in neurones. **Conclusions:**: These results show that RTN3 is primarily expressed in pyramidal neurones of the human cerebral cortex and that no clear difference of RTN3 immunoreactivity is observable between control and AD brains. Our data also suggest that there is considerable colocalization of RTN3 with BACE1 at a subcellular level.

3.1231 A high-cholesterol diet increases the association between caveolae and insulin receptors in rat liver
Hahn-Obercyger, M., Graeve, L. and Madar, Z.
J. Lipid Res., ***50***, *98-107 (2009)*

Caveolin-1, a component of caveolae, regulates signaling pathway compartmentalization by interacting with tyrosine (Tyr) kinase receptors and their substrates. Perturbations in caveolae lipid composition have been shown in vitro to displace proteins from lipid microdomains, thereby altering their functionality and subsequent downstream signaling. The role of caveolin-1 in insulin receptor (IR) signaling has been widely investigated in vitro mainly in 3T3-L1 adipocyte cells. However, in vivo experiments investigating this connection in liver tissue have not been carried out. The objective of the present study was to investigate the effects of a high-cholesterol diet on caveolin-1 expression and IR localization and activity in the rat liver. Compared with a standard diet, rats fed with diet rich in cholesterol significantly altered liver caveolae by increasing both caveolin-1 (66%, $P < 0.05$) and caveolin-2 (55%, $P < 0.05$) expression while caveolin-1 mRNA levels were reduced. Concomitantly, a 25% increase in localization of the caveolae-resident signaling protein IR was observed. The distribution of caveolar and noncaveolar phosphorylated IR was unaffected but insulin-induced IR activation was significantly enhanced following consumption of the high-cholesterol diet (120%, $P < 0.001$). However, the downstream molecules IRS-1 and Akt have shown impaired activity in cholesterol-fed rats suggesting insulin resistance condition. Insulin stimulation failed to induce Tyr phosphorylation of caveolin-1 in cholesterol-fed rats. These findings suggest a mechanism by which a high-cholesterol diet altered caveolin-1 expression in vivo accompanied by altered IR localization and activity.

3.1232 Membrane microdomains from early gastrula embryos of medaka, Oryzias latipes , are a platform of E-cadherin- and carbohydrate-mediated cell–cell interactions during epiboly
Adachi, T., Sato, C., Kishi, Y., Totani, K., Murata, T., Usui, T. and Kitajima, K.
Glycoconj. J., ***26***, *285-299 (2009)*

Formation of membrane microdomain is critical for cell migration (epiboly) during gastrulation of medaka fish [Adachi *et al*. (Biochem. Biophys. Res. Commun. 358:848–853, *2007*)]. In this study, we characterized membrane microdomain from gastrula embryos to understand its roles in epiboly. A cell adhesion molecule (E-cadherin), its associated protein (β-catenin), transducer proteins (PLCγ, cSrc), and a cytoskeleton protein (β-actin) were enriched in the membrane microdomain. Le^X-containing glycolipids and glycoproteins (Le^X-gp) were exclusively enriched in the membrane microdomain. Interestingly, the isolated membrane microdomain had the ability to bind to each other in the presence of Ca^{2+}. This membrane microdomain binding was achieved through the E-cadherin homophilic and the Le^X-glycan-mediated interactions. E-cadherin and Le^X-gp were co-localized on the same membrane microdomain, suggesting that these two interactions are operative at the same time. Thus, the membrane microdomain functions as a platform of the E-cadherin- and Le^X-glycan-mediated cell adhesion and signal transduction.

3.1233 Src Family Kinases Accelerate Prolactin Receptor Internalization, Modulating Trafficking and Signaling in Breast Cancer Cells
Piazza, T.M., Lu, J-C., Carver, K.C. and Schuler, L.A.
Mol. Endocrinol., ***23***, *202-212 (2009)*

Despite the growing body of evidence supporting prolactin (PRL) actions in human breast cancer, little is known regarding PRL regulation of its own receptor in these cells. Ligand-initiated endocytosis is a key process in the regulation of receptor availability and signaling cascades that may lead to oncogenic actions. Although exposure to exogenous PRL accelerates degradation of the long isoform of the PRL receptor (lPRLR), neither the signals initiated by PRL that lead to lPRLR internalization and subsequent down-regulation, nor the relationship to downstream pathways are understood in breast cancer cells. In this study, we showed that PRL-induced down-regulation of the lPRLR was reduced by inhibition of src family kinases (SFKs), but not Janus kinase 2, in MCF-7 cells. Inhibition of SFKs also resulted in accumulation of

a PRL-induced PRLR fragment containing the extracellular domain, which appeared to be generated from newly synthesized PRLR. lPRLR was constitutively associated with SFKs in lipid rafts. PRL-induced SFK activation led to recruitment of the guanosine triphosphatase, dynamin-2, to an internalization complex, resulting in endocytosis. Inhibition of endocytosis by small interfering RNA-mediated knockdown of dynamin-2 blocked PRL-induced down-regulation of lPRLR, confirming that internalization is essential for this process. Endocytosis also was required for optimal phosphorylation of ERK1/2 and Akt, but not for Janus kinase 2 or signal transducer and activator of transcription 5, indicating that internalization selectively modulates signaling cascades. Together, these data indicate that SFKs are key mediators of ligand-initiated lPRLR internalization, down-regulation, and signal transduction in breast cancer cells, and underscore the importance of target cell context in receptor trafficking and signal transduction.

3.1234 Downregulation of sodium transporters and NHERF proteins in IBD patients and mouse colitis models: Potential contributors to IBD-associated diarrhea

Sullivan, S., Alex, P., Dassopoulos, T., Zachos, N.C., Iacobuzio-Donahue, C., Donowitz, M., Brant, S.R., Cuffari, C., Harris, M.L., Wu Datta, L., Conklin, L., Chen, Y. and Li, X.
Inflamm. Bowel. Dis., ***15(2)***, *261-274 (2009)*

Background: One of the most common symptoms among patients with inflammatory bowel disease (IBD) is diarrhea, which is thought to be contributed by changes in electrolyte transport associated with intestinal inflammation. This study was designed to test the hypothesis that intestinal Na+-related transporters/channels and their regulatory proteins may be downregulated as a potential contributor to IBD-associated diarrhea.
Methods: SDS-PAGE and Western blotting and/or confocal immunomicroscopy were used to examine the expression of Na+/H+-exchangers 1-3 (NHE1-3), epithelial Na+ channel (ENaC), Na+/K+-ATPase, the intracellular Cl- channel 5 (ClC-5), and NHE3 regulatory factors (NHERF1,2) in ileal and colonic pinch biopsies from IBD patients and noninflammatory controls, as well as from colonic mucosa of dextran sodium sulfate (DSS)- and TNBS-induced acute murine IBD models.
Results: NHE1,3 (but not NHE2), β-ENaC, Na+/K+-ATPase-α, ClC-5, and NHERF1 were all downregulated in sigmoid mucosal biopsies from most cases of active UC and/or CD compared to controls. NHE3 was also decreased in ileal mucosal biopsies of active CD, as well as in ≈50% of sigmoid biopsies from inactive UC or CD. Importantly, similar downregulation of NHE1,3, β-ENaC, and NHERF1,2 was also observed in the mouse colon (but not ileum) of DSS- and TNBS-induced colitis.
Conclusions: IBD-associated diarrhea may be due to a coordinated downregulation of multiple Na+ transporter and related regulatory proteins, including NHE1,3, Na+/K+-ATPase, and ENaC, as well as NHERF1,2, and ClC-5, all of which are involved directly or indirectly in intestinal Na+ absorption.

3.1235 Guanosine Triphosphate Cyclohydrolase I Expression and Enzymatic Activity Are Present in Caveolae of Endothelial Cells

Peterson, T.E., d'Uscio, L.V., Cao, S., Wang, X-L. and Katusic, Z.S.
Hypertension, ***53***, *189-195 (2009)*

Tetrahydrobiopterin is an essential cofactor required for the synthesis of NO. GTP cyclohydrolase I (GTPCH I) is the rate-limiting enzyme for tetrahydrobiopterin production in endothelial cells, yet little is known about the subcellular localization of this enzyme. In this study, we demonstrated that GTPCH I is localized to caveolar membrane microdomains along with caveolin-1 and endothelial NO synthase. GTPCH I activity was detected in isolated caveolar membranes from cultured endothelial cells. Confocal and electron microscopy analyses confirmed GTPCH I colocalization with caveolin-1. Consistent with in vitro studies, GTPCH I activity was evident in isolated caveolar microdomains from lung homogenates of wild-type mice. Importantly, a 2-fold increase in GTPCH I activity was detected in the aortas of caveolin-1–deficient mice, suggesting that caveolin-1 may be involved in the control of GTPCH I enzymatic activity. Indeed, overexpression of caveolin-1 inhibits GTPCH I activity, and tetrahydrobiopterin biosynthesis is activated by the disruption of caveolae structure. These studies demonstrate that GTPCH I is targeted to caveolae microdomains in vascular endothelial cells, and tetrahydrobiopterin production occurs in close proximity to endothelial NO synthase. In addition, our findings provide new insights into the regulation of GTPCH I activity by the caveolar coat protein, caveolin-1.

3.1236 **Isolation of rafts from mouse brain tissue by a detergent-free method**
Persaud-Sawin, D-A., Lightcap, S. and Harry, G.J.
J. Lipid Res., ***50***, *759-767 (2009)*

Membrane rafts are rich in cholesterol and sphingolipids and have specific proteins associated with them. Due to their small size, their identification and isolation have proved to be problematic. Their insolubility in nonionic detergents, such as Triton-X 100, at 4°C has been the most common means of isolation. However, detergent presence can produce artifacts or interfere with ganglioside distribution. The direction is therefore toward the use of detergent-free protocols. We report an optimized method of raft isolation from lipid-rich brain tissue using a detergent-free method. We compared this to Triton-X 100-based isolation along sucrose or **Optiprep**™ gradients using the following endpoints: low protein content, high cholesterol content, presence of Flotillin 1 (Flot1), and absence of transferrin receptor (TfR) proteins. These criteria were met in raft fractions isolated in a detergent-free buffer along a sucrose gradient of 5%/35%/42.5%. The use of **optiprep** gave less consistent results with respect to protein distribution. We demonstrate that clean raft fractions with minimal myelin contamination can be reproducibly obtained in the top three low-density fractions along a sucrose step gradient.

3.1237 **Lipid Raft Segregation Modulates TRPM8 Channel Activity**
Morenilla-Palao, C., Pertusa, M., Meseguer, V., Cabedo, H. and Viana, F.
J. Biol. Chem., ***284(14)***, *9215-9224 (2009)*

Transient receptor potential channels are a family of cation channels involved in diverse cellular functions. Most of these channels are expressed in the nervous system and play a key role in sensory physiology. TRPM8 (transient receptor potential melastatine 8), a member of this family, is activated by cold, cooling substances such menthol and icilin and voltage. Although TRPM8 is a thermosensitive channel highly expressed in cold sensory neurons, the mechanisms underlying its temperature sensitivity are still poorly understood. Here we show that, in sensory neurons, TRPM8 channel is localized in cholesterol-rich specialized membrane domains known as lipid rafts. We also show that, in heterologous expression systems, lipid raft segregation of TRPM8 is favored by glycosylation at the Asn^{934} residue of the polypeptide. In electrophysiological and imaging experiments, using cold and menthol as agonists, we also demonstrate that lipid raft association modulates TRPM8 channel activity. We found that menthol- and cold-mediated responses of TRPM8 are potentiated when the lipid raft association of the channel is prevented. In addition, lipid raft disruption shifts the threshold for TRPM8 activation to a warmer temperature. In view of these data, we suggest a role for lipid rafts in the activity and temperature sensitivity of TRPM8. We propose a model wherein different lipid membrane environments affect the cold sensing properties of TRPM8, modulating the response of cold thermoreceptors.

3.1238 **The amino-terminal region of Atg3 is essential for association with phosphatidylethanolamine in Atg8 lipidation**
Hanada, T., Satomi, Y., Takao, T. and Ohsumi, Y.
FEBS Lett., ***583***, *1078-1083 (2009)*

Autophagy is a bulk degradation process conserved among eukaryotes. In macro-autophagy, autophagosomes sequester cytoplasmic components and deliver their contents to lysosomes/vacuoles. Autophagosome formation requires the conjugation of Atg8, a ubiquitin-like protein, to phosphatidylethanolamine (PE). Here we report that the amino (N)-terminal region of Atg3, an E2-like enzyme for Atg8, plays a crucial role in Atg8–PE conjugation. The conjugating activities of Atg3 mutants lacking the 7 N-terminal amino acid residues or containing a Leu-to-Asp mutation at position 6 were severely impaired both in vivo and in vitro. In addition, the amino-terminal region is critical for interaction with the substrate, PE.

3.1239 **Acute hypertension provokes acute trafficking of distal tubule Na-Cl cotransporter (NCC) to subapical cytoplasmic vesicles**
Lee, D.H., Riquier, A.D.M., Yang, L.E., Leong, P.K.K., Maunsbach, A.B. and McDonough, A.A.
Am. J. Physiol. Renal Physiol., ***296***, *F810-F818 (2009)*

When blood pressure (BP) is elevated above baseline, a pressure natriuresis-diuresis response ensues, critical to volume and BP homeostasis. Distal convoluted tubule Na^+-Cl^- cotransporter (NCC) is regulated by trafficking between the apical plasma membrane (APM) and subapical cytoplasmic vesicles (SCV). We aimed to determine whether NCC trafficking contributes to pressure diuresis by decreasing APM NCC or compensates for increased volume flow to the DCT by increasing APM NCC. BP was raised 50 mmHg (high BP) in rats by arterial constriction for 5 or 20–30 min, provoking a 10-fold diuresis at both times. Kidneys were excised, and NCC subcellular distribution was analyzed by *1*) sorbitol density gradient fractionation and immunoblotting and *2*) immunoelectron microscopy (immuno-EM). NCC distribution did not change after 5-min high BP. After 20–30 min of high BP, 20% of NCC redistributed from low-density, APM-enriched fractions to higher density, endosome-enriched fractions, and, by quantitative immuno-EM, pool size of APM NCC decreased 14% and SCV pool size increased. Because of the time lag of the response, we tested the hypothesis that internalization of NCC was secondary to the decrease in ANG II that accompanies high BP. Clamping ANG II at a nonpressor level by coinfusion of captopril (12 μg/min) and ANG II (20 $ng \cdot kg^{-1} \cdot min^{-1}$) during 30-min high BP reduced diuresis to eightfold and prevented redistribution of NCC from APM- to SCV-enriched fractions. We conclude that DCT NCC may participate in pressure natriuresis-diuresis by retraction out of apical plasma membranes and that the retraction is, at least in part, driven by the fall in ANG II that accompanies acute hypertension.

3.1240 **Phosphotyrosine-dependent *in vitro* reconstitution of recombinant LAT-nucleated multiprotein signalling complexes on liposomes**

Sangani, D., Venien-Bryan, C. and Harder, T.
Mol. Membrane Biol., ***26(2)***, *159-170 (2009)*

Numerous cell surface receptors propagate activation signals to the interior of the cell via tyrosine phosphorylation of transmembrane proteins. This leads to the phosphotyrosine (PiY)-mediated recruitment of cytoplasmic signalling protein complexes which catalyze crucial biochemical signalling reactions. Here we describe the first *in vitro* reconstitution of such PiY-nucleated protein complexes on an artificial lipid membrane. A tyrosine phosphorylated recombinant variant of the transmembrane adaptor protein Linker for Activation of T cells (PiYLAT) was anchored in liposomes. These PiYLAT proteoliposomes specifically recruited cooperative high avidity signalling protein complexes from Jurkat cytosol. Nucleation of signalling protein assemblies readily occurred on PiYLAT liposomes composed of phosphatidylserine, but not on PiYLAT liposomes composed of phosphatidylcholine. Purified recombinant grb2 alone did not stably associate with tyrosine phosphorylated LAT proteoliposomes. However, when grb2 was presented to the PiYLAT proteoliposomes in the context of Jurkat cytosol it was incorporated into multiprotein signalling complexes. Together the data suggest that these reconstituted high-avidity signalling protein complexes represent a cooperative protein network. This novel *in vitro* approach offers a novel technology permitting biochemical, structural, and pharmacological analyses of plasma membrane receptor signalling complexes.

3.1241 **Renal NHE3 and NaPi2 partition into distinct membrane domains**

Riquuier, A.D.M., Lee, D.H., and McDonough, A.A.
Am. J. Physiol. Cell Physiol., ***296***, *C900-C910 (2009)*

Hypertension provokes differential trafficking of the renal proximal tubule Na^+/H^+ exchanger 3 (NHE3) to the base of the apical microvilli and Na^+-P_i cotransporter 2 (NaPi2) to endosomes. The resultant diuresis and natriuresis are key to blood pressure control. We tested the hypothesis that this differential trafficking of NHE3 vs. NaPi2 was associated with partitioning to distinct membrane domains. In anesthetized rats, arterial pressure was increased (104 ± 2 to 142 ± 4 mmHg, 15 min) by arterial constriction and urine output increased 23-fold. Renal membranes were fractionated by cold 1% Triton X-100 extraction then centrifugation through **OptiPrep** flotation gradients. In controls, 84 ± 9% of NHE3 localized to flotillin-enriched lipid raft domains and 69 ± 5% of NaPi2 localized to transferrin receptor-enriched nonrafts. MyosinVI and dipeptidyl peptidase IV, associated with NHE3 regulation, coenriched in lipid rafts with NHE3, while NHE regulatory factor-1 coenriched in nonrafts with NaPi2. Partitioning was not altered by hypertension. Detergent insoluble membranes were pelleted after detergent extraction. NHE3 detergent insolubility decreased as it redistributed from body (80 ± 10% detergent insoluble) to base (75 ± 3%) of the apical microvilli, while NaPi2 partitioned into more insoluble domains as it moved from the microvilli (45 ± 7% detergent insoluble) to endosomes (82 ± 1%). In conclusion, NHE3 and NaPi2, while both localized to apical microvilli, are segregated into domains: NHE3 to lipid rafts and NaPi2 to nonrafts. These domain properties may play a role in the distinct trafficking patterns observed during elevated pressures: NHE3 remains in rafts and settles to the base of the microvilli while NaPi2 is freely endocytosed.

3.1242 Soybean proteomics and its application to functional analysis
Komatsu, S. and Ahsan, N.
*J. Proteomics, **72**, 325-336 (2009)*

Complete genome sequences, which are available for rice and *Arabidopsis*, provide insights into many fundamental aspects of plant biology; they do not, however, address some important aspects of legume biology. Legumes are important for maintenance of human health and as crops for sustainable agriculture. Two model species of legume, *Lotus japonicus* and *Medicago truncatula*, have been the focus of projects on genome sequencing and functional genomics. A project aimed at sequencing the genome of the agricultural legume soybean recently began, but functional genomics studies of this plant are in their infancy, and therefore proteomics approaches could be a powerful tool for functional analysis. In this review, we discuss the strengths and weaknesses of proteomics technologies in soybean biology and we examine the limitations of current techniques.

3.1243 Hydroponics on a chip: Analysis of the Fe deficient Arabidopsis thylakoid membrane proteome
Laganowsky, A., Gomez, S.M., Whitelegge, J.P. and Nishio, J.N.
*J. Proteomics, **72(3)**, 397-415 (2009)*

The model plant *Arabidopsis thaliana* was used to evaluate the thylakoid membrane proteome under Fe-deficient conditions. Plants were cultivated using a novel hydroponic system, called "hydroponics on a chip", which yields highly reproducible plant tissue samples for physiological analyses, and can be easily used for *in vivo* stable isotope labeling. The thylakoid membrane proteome, from intact chloroplasts isolated from Fe-sufficient and Fe-deficient plants grown with hydroponics on a chip, was analyzed using liquid chromatography coupled to mass spectrometry. Intact masses of thylakoid membrane proteins were measured, many for the first time, and several proteins were identified with post-translational modifications that were altered by Fe deficiency; for example, the doubly phosphorylated form of the photosystem II oxygen evolving complex, PSBH, increased under Fe-deficiency. Increased levels of photosystem II protein subunit PSBS were detected in the Fe-deficient samples. Antioxidant enzymes, including ascorbate peroxidase and peroxiredoxin Q, were only detected in the Fe-deficient samples. We present the first biochemical evidence that the two major LHC IIb proteins (LHCB1 and LHCB2) may have significantly different functions in the thylakoid membrane. The study illustrates the utility of intact mass proteomics as an indispensable tool for functional genomics. "Hydroponics on a chip" provides the ability to grow *A. thaliana* under defined conditions that will be useful for systems biology.

3.1244 Advancements in plant proteomics using quantitative mass spectrometry
Oeljeklaus, S., Meyer, H.E. and warscheid, B.
*J. Proteomics, **72(3)**, 545-554 (2009)*

Due to innovative advancements in quantitative MS technologies, proteomics has evolved from taking mere "snapshots" of distinct proteomes in a defined state to monitoring, for instance, changes in abundance, location and/or posttranslational modification(s) of proteins under various conditions, thereby facilitating the functional characterization of proteins in large scale experiments. In plant biology, MS-based quantitative proteomics strategies utilizing stable isotope labeling or label-free methods for protein quantification have only recently been started to find increasing application to comparative and functional proteomics analyses. This review summarizes latest trends and applications in MS-based quantitative plant proteomics and provides insight into different technologies available. In addition, the studies presented here illustrate the enormous potential of quantitative MS for the analysis of important functional aspects with the emphasis on organellar and phosphoproteomics as well as dynamics and turnover of proteins in plants.

3.1245 Long-Distance Delivery of Bacterial Virulence Factors by *Pseudomonas aeruginosa* Outer Membrane Vesicles
Bomberger, J.M., Maceachran, D.P., Coutermarsh, B.A., Ye, S., O'Toole, G.A. and Stanton, B.A.
*PloSPathogens, **5(4)**, e1000382 (2009)*

Bacteria use a variety of secreted virulence factors to manipulate host cells, thereby causing significant morbidity and mortality. We report a mechanism for the long-distance delivery of multiple bacterial virulence factors, simultaneously and directly into the host cell cytoplasm, thus obviating the need for

direct interaction of the pathogen with the host cell to cause cytotoxicity. We show that outer membrane–derived vesicles (OMV) secreted by the opportunistic human pathogen *Pseudomonas aeruginosa* deliver multiple virulence factors, including β-lactamase, alkaline phosphatase, hemolytic phospholipase C, and Cif, directly into the host cytoplasm via fusion of OMV with lipid rafts in the host plasma membrane. These virulence factors enter the cytoplasm of the host cell via N-WASP–mediated actin trafficking, where they rapidly distribute to specific subcellular locations to affect host cell biology. We propose that secreted virulence factors are not released individually as naked proteins into the surrounding milieu where they may randomly contact the surface of the host cell, but instead bacterial derived OMV deliver multiple virulence factors simultaneously and directly into the host cell cytoplasm in a coordinated manner.

3.1246 Characterization of a myristoylated, monomeric HIV Gag protein
Dou, J., Wang, J-J., Chen, X., Li, H., Ding, L. and Spearman, P.
Virology, ***387***, *341-352 (2009)*

The process of HIV assembly requires extensive homomultimerization of the Gag polyprotein on cellular membranes to generate the nascent particle bud. Here we generated a full-length, monomeric Gag polyprotein bearing mutations that eliminated multimerization in living cells as indicated by fluorescence resonance energy transfer (FRET). Monomeric Gag resembled non-myristoylated Gag in its weak membrane binding characteristics and lack of association with detergent-resistant membranes (DRMs or lipid rafts). Monomeric Gag failed to assemble virus-like particles, but was inefficiently rescued into particles by wildtype Gag through the influence of the matrix domain. The subcellular distribution of monomeric Gag was remarkably different than either non-myristoylated Gag or wildtype Gag. Monomeric Gag was found on intracellular membranes and at the plasma membrane, where it highlighted plasma membrane extensions and ruffles. This study indicates that monomeric Gag can traffic to assembly sites in the cell, where it interacts weakly with membranes.

3.1247 Subcellular fractionation of human eosinophils: Isolation of functional specific granules on isoosmotic density gradients
Neves, J.S., Perez, S.A.C., Spencer, L.A., Melo, R.C.N. and Weller, P.F.
J. Immunol., Methods, ***344***, *64-72 (2009)*

Subcellular fractionation has been an important tool in investigating human eosinophil structure and function, including localizing of cytokine/chemokines within granules, investigating granule protein translocation and intracellular transport during eosinophil secretion, and studying secretory mechanisms of granules. The resolution of organelles obtained by subcellular fractionation was improved considerably after the introduction of nonionic iodinated density-gradient metrizamide and Nycodenz media that, unlike sucrose, exhibit relatively low tonicity throughout the gradient. However, the structure and membrane preservation of isolated organelles were still compromised due to the lack of gradient isoosmolarity. This paper describes a detailed protocol of subcellular fractionation of nitrogen cavitated eosinophils on an isoosmotic iodinated density gradient (iodixanol – OptiPrep) and the isolation of well preserved and functional membrane-bound specific granules.

3.1248 Mitochondrial degeneration and not apoptosis is the primary cause of embryonic lethality in ceramide transfer protein mutant mice
Wang, X., Rao, R.P., Kasakowska-Cholody, T., Massod, M.A., Southon, E., Zhang, H., Berthel, C., Nagashim, K., Veenstra, T.K., Tessarollo, L., Acharya, U. and Acharya, J.K.
J. Cell Biol., ***184(1)***, *143-158 (2009)*

Ceramide transfer protein (CERT) functions in the transfer of ceramide from the endoplasmic reticulum (ER) to the Golgi. In this study, we show that CERT is an essential gene for mouse development and embryonic survival and, quite strikingly, is critical for mitochondrial integrity. CERT mutant embryos accumulate ceramide in the ER but also mislocalize ceramide to the mitochondria, compromising their function. Cells in mutant embryos show abnormal dilation of the ER and degenerating mitochondria. These subcellular changes manifest as heart defects and cause severely compromised cardiac function and embryonic death around embryonic day 11.5. In spite of ceramide accumulation, CERT mutant mice do not die as a result of enhanced apoptosis. Instead, cell proliferation is impaired, and expression levels of cell cycle–associated proteins are altered. Individual cells survive, perhaps because cell survival mechanisms are activated. Thus, global compromise of ER and mitochondrial integrity caused by ceramide accumulation in CERT mutant mice primarily affects organogenesis rather than causing cell death via apoptotic pathways.

3.1249 Akt-Mediated Transactivation of the S1P1 Receptor in Caveolin-Enriched Microdomains Regulates Endothelial Barrier Enhancement by Oxidized Phospholipids

Singleton, P.A., Chatchavalvanich, C., Fu, P., Xing, J., Birukova, A.A., Fortune, J.A., Klibanov, A.M., garcia, J.G.N. and Birukov, K.G.

Circ. Res., ***104****, 978-986 (2009)*
